and as it may be set free at a late period patients should

be cautioned against violent efforts or straining for some

time after an abdominal operation. I lost a patient from

this accident during the third week after operation, she had

been sitting by the fire talking to the other patients and

was in the act of pulling off her boots when she suddenly

was seized with a feeling of suffocation, precordial anxiety,

gasping respiration, and cyanosis, and she died in a few

minutes

Of tetanus I have had no personal experience

PERITONITIS.

A question of much importance is, whether peritonitis is

always septic? Many would answer this question in the

affirmative, but there is much to be said on the other side.

There is a condition called traumatic or plastic peritonitis,

it is best marked in cases where the intestines have been

long exposed and much manipulated and where wide areas

of adhesion have been separated. In the worst forms of

this affection there are vomiting, severe pain in the lower

abdomen, tympanitis, tenderness on pressure, accelerated

pulse, and elevation of temperature. Death may result in

such cases from pressure of the distended intestines on the

diaphragm or from ileus. The treatment of this condition

recommended some years ago by Lawson Tait—namely,

free punctation—i.e., I believe at the present time the recog-

nized method. The non infective character of many of

these inflammations has been proved by Howard Kelly

who, when obliged to reopen the abdomen to relieve

obstructed bowels, found extensive union between adjacent

peritoneal surfaces, but these cases failed to show any kind

of micro-organisms in the peritoneal cavity and yet the

evidence of the pointing out of a plastic lymph with the

subsequent formation of adhesions was abundant

I now come to septic infection. The part played by

living organisms in the production of disease has been most

firmly established by many infallible proofs, and appears

to me as certain as the law of gravitation or the shape of the

earth. Some who place their faith in procuring an absolutely

septic conditions spare no pains in a variety of this objec-

while others regard septic conditions as an extreme ritualist,

and having at the bottom of their minds as extreme ritualist,

some even describing all procedures excepting cleanliness and still

in operating. For myself I must confess that I am a

perfect aseptic treatment consists essentially in

perfect cleanliness and whatever others may say I have no

hesitation in stating that the doctrine of cleanliness origi-

nated with, and has been based upon, the reasoning and

practice of Lawson Tait and Bantock. Years ago, whilst

most of us were practising antiseptic methods, they in the

face of bitter opposition insisted upon the importance of

perfect cleanliness and pointed out the importance of

chemical substances in irritating and poisoning the tissues

And at the present time we differ from them only in the

meaning of the word "perfect," for whilst they are in a great

measure obtain not only microscope but also microscopic

cleanliness.

By perfect asepsis then, we understand that everything

which comes in contact with the field of operation must be

absolutely pure. Every thing touches not only the operator

and his assistants but instruments and dressings, but also

the air and water. An operation may be carried out

separately in any ordinary room, but this is not covered with

great difficulty and risk, so that in my opinion so serious a

procedure as compulsory asepsis should be performed in a

circumstances of emergency, it may be performed in a

special apartment constructed for the purpose, ample

supplies of pure water and good light, and heated to about

100° F.

[Dr Smiley here described the arrangement of the

of the rectum was lacerated all round its circumference from the anus to the upper end of the wound—that is, for seven inches from the anal opening. The omentum was adherent by an old adhesion to the caecum and presented near the adherent point a small recent bruise. On lifting it up, lying between the colon and the right kidney, which was moveable, was found a cake of soap considerably worn, three inches long by two inches broad and three quarters of an inch thick. The Fallopian tubes showed old salpingitis. The uterus was nulliparous, all the other organs were healthy. Although the woman was said to have been very drunk, the only sign noticed was a slight smell in her breath on admission. Post mortem there was no smell or other indication of alcohol or any other drug in the stomach contents. The man having been arrested was tried and condemned for the murder of the patient.

The first question which arose was whether these injuries could have been self inflicted. The situation, extent, and severity of the wounds are all much against this theory. It is conceivable that a person might by thrusting an instrument up the rectum produce a perforation of the rectum or that such might be the result of accidentally sitting down on some sharp spike, as in various recorded cases, but these theories would not account for the excessive lacerations, the injuries to the vagina and the dilatation and rupture of the sphincter. Also, in these cases an instrument would have been found near the patient, while had it been the result of an accident some noise would have been heard and the patient would certainly have tried to get assistance. The motive for the infliction of the injuries is very obscure. It is not likely that they were the result of an attempt at an abortion, since both rectum and vagina were injured, and there is no reason from the post-mortem examination to think that the patient imagined herself pregnant. Lust-murder might be suggested, but against this is the evidence that there was no noise heard no sounds of a struggle, and that the woman made no complaint of an attempt to harm her. Although this part of the landlady's evidence seems almost incredible seeing the excruciating pain that the infliction of these injuries must have caused even in a drunken person, yet there was no reason for the landlady to have concealed the fact and she heard anything out of the common, and it is therefore, I think fair to assume that the patient was a consenting party to the infliction of the injuries. Without doubt the piece of soap itself was incapable of causing the injuries, and it must have entered the peritoneal cavity after the perforation of the rectum had been made. It is possible that it was introduced into the rectum for some immoral purpose and that the injuries resulted from the clumsy attempts made to remove it, and this seems the most reasonable explanation of the crime.

Then comes the question as to the means by which the injuries were inflicted. The wounds of both vagina and rectum could have been easily explained if some rough instrument had been used and the bruise on the omentum would be accounted for by assuming that such an instrument passed through the perforation of the rectum, but no instrument was found in the house, although of course it might have been cleared away by the landlady. It is possible that the injuries were caused by the introduction of the hand into the rectum. Introduction of the fingers alone into the rectum could not have caused the laceration of the mucous membrane seven inches from the anus, and considering the large foreign bodies mentioned in the text-books which have been found in the rectum without causing much damage it is obvious that great violence must have been used. The man had been wearing a gold buckle ring with a projecting tag to the buckle, and although this might have caused laceration of the rectal mucous membrane it is somewhat doubtful if it would have inflicted the deep scores which were present in the tough vaginal mucous membrane, which it is fair to infer were inflicted by the same means as the rectal injuries, and therefore it is more probable that the injuries were inflicted by an instrument than by the hand, although no such instrument was found. No incriminating evidence could be found on the man although there were a few trivial blood stains on his clothing, but these were not more, either could easily be accounted for. However, he should be reports which I have heard, apart from the ex with her head in court, to be a sexual pervert.

Taking all the facts into consideration (fetus and stimulus) conclusion seems to be that the injuries at enema in such the clumsy attempt by the condemned man containing two

soap which had previously been introduced into the rectum of the woman who was a consenting party to the attempts, but that whether the injuries were caused by an instrument or by the hand it is impossible to say.

Hull

A CASE OF CYSTICERCUS CELLULOSE

By JOHN H. GOODLIFFE, M.D. ABERD.

SENIOR ASSISTANT MEDICAL OFFICER, COUNTY ASYLUM, BERRYWOOD, NORTHAMPTON.

THE occurrence of the larval stage of the *tænia solium* is, I believe, uncommon in the human subject in this country, and the following case may therefore be of interest.

The patient in whom the cysticercus was found was an epileptic dement who had been an inmate of the asylum for more than five years at the time of her death. Any previous history was unobtainable, except that she had lived a considerable time in India. On admission the patient was hemiplegic, and this condition persisted up to the time of her death. She was very demented, and was in the habit of eating leaves and rubbish which she picked up. She never complained of any definite symptoms whilst in the asylum. Death was due to diarrhoea and exhaustion. The presence of the parasite was not suspected during life. At the necropsy small calcareous nodules of about the size of a lentil seed were found in the subcutaneous tissues throughout the body. They could be easily felt through the skin in most parts and were quite moveable. On opening the pericardium the heart was seen to be studded with calcareous bodies, varying in size from that of a pea to that of a small marble. In addition to these a few cysts containing clear fluid were found, some of which had calcareous deposits in their walls whilst others had calcareous matter in the form of granules lying loose in the fluid contents. The condition was best seen on the posterior aspect of the left ventricle. There was no

Figure showing the position of the cysticercus cellulose in the abdominal cavity. In any case acute employed to induce the bowels be washed out and copiously with a long tube, and dilute it calomel, Glauber or be administered. Should these abdomen should be reopened with the prognosis. As to prophylactic measures evidence of the position is one of the most important condition of the bowels are out of the way and are not disturbed, but especial care must be taken when the patient is restored to the horizontal position in arranging the intestines in their normal position and seeing that they preserve their natural relation to the omentum. Coating raw surfaces with collodium has been recommended and Martin of Berlin introduces a sponge soaked in sterilised oil, but most operators attach more importance to drawing down the omentum between the abdominal wound and the intestines and as far as possible covering all raw surfaces with peritoneum.

[illegible]

A CASE OF COLLOID CARCINOMA OF THE BREAST, RECURRENT AND DISSEMINATION

BY O E M KELLY, M D, M S LOND, F R O S ENG,

W D'ESTE EMERY M D, B SO LOVD

THE history of this case is that in June, 1890, the patient a married woman, 39 years of age, was admitted

HILL, the greater part of the breast being removed, for a growth which was thought to be duct-epithelioma. (The tumour is described and illustrated in "Erb's System of Surgery," vol II, p 281, tenth edition.) There was no recurrence until December, 1894, when she noticed a small lump in the same breast, but as it was painless she did not have any thing done, although it was increasing in size, until August, 1896, when she was again admitted to University College Hospital. It was then found that the seat of the disease, extending obliquely upwards to within two inches of the axilla, had enlarged to within two inches of the axilla. At the upper end, the one on the chest wall was rounded and caused a little cyst which could be picked up. The other was thin and sharp edged and was placed over the pectoral muscle. By perfect asepsis, then, we undertook to remove the growth which comes in contact with the field of operation, absolutely pure. "Every thing," and not only the air and water, but the instruments and dressings, was sterilized by dry heat, and the patient was kept in an ordinary room, but as the growth was so close to the axilla, so that it was impossible to get away from it, we had to operate under a special arrangement, with pure air from draughts, and supplies of pure water and good light and heated to about 80° F.] Dr Smyly here described the arrangement of the

the lungs the nodules were much smaller, but there was a considerable amount of colloid degeneration which, however, reached its greatest development in the sternum, the manubrium being practically entirely replaced by a mass on the substance, the bone being almost entirely removed. In this situation each small alveolus of growth was surrounded by a thick layer of colloid. The growth also extended into the body of the sternum but was less advanced in this situation.

The chief interest is attached to the growth in the skull and sections were made of the edge of the aperture in this bone with the membrane near it. The bone was found to be undergoing a process of rarefaction, this being most marked nearest to the edge of the gap. The spaces left were filled up by young-looking fibrous tissue with elongated or spindle-

and deeply, appeared to be degenerated, while the alveoli were smaller and less numerous in proportion as they were distant from the bone. There was no trace of any colloid change in any part of the bone or membrane.

It would appear that this remarkable aperture in the skull was formed by a process of absorption of the bone running parallel with the deposit of alveoli of carcinoma cells and probably the new formation of fibrous tissue and that the alveoli of growth had but a short life and did not attain any large size so as to form a definite tumour, but, on the contrary, rapidly underwent degeneration so as to leave in place of the original bone merely a membrane containing a few compact masses of nuclei the remains of the original growth. This fibrous tissue was much denser than where it occupied the interstices of the bone and with the dura mater and

FIG 1

Microphotograph illustrating the deposit of cancer in the membranous part of the skull. $\times 30$.

FIG 2

Illustrating the change in the skull at the edge of the deposit of cancer $\times 30$.

shaped nuclei and in the middle of this fibrous tissue were round or oval alveoli of growth, these being most numerous where the bone ceased. The cells composing them had round nuclei which were very prominent, but their protoplasm was indistinct, in many cases nothing but nuclei could be made out. When these alveoli of growth were traced into the membrane they were found to become much more compact and only the nuclei were visible, all traces of protoplasm disappearing, and these nuclei, although staining well

FIG 3

FIG 4

Figs. 3 and 4 show the absorption of the true bone and its replacement by cancerous material. $\times 110$.

periosteum added was not more than one-eighth of an inch thick.

The most interesting points in the case appear to be the curious appearance of the primary growth which so closely resembles a duct-papilloma. The growth progressed at the average rate in most reported cases of this variety of cancer, the secondary recurrence occurring in three and a half years and death in eight years. No glandular enlargement

upwards and backwards so that the points of future approximation come together. I think, too, that some help is given by tying each stitch as it is passed, leaving the ends long for holding up the gut wall, but the stitch passing through the floor of the space is more easily placed before those immediately beside it are tied and tied afterwards. The tendency is usually to pass the first stitch further behind the left mesentery than originally intended, but this is a matter of no practical importance, as it only means an addition to the number of inter-mesenteric stitches.

If Mansell's method be preferred the separation of the two mesenteries is easily effected by passing the first guiding suture through the walls of the segment in front of one mesentery and behind the other, the second thread is passed at the opposite point to the first and the operation proceeds as usual. It must be borne in mind that the longitudinal incision is not in a line with the second stitch, but is opposite the mesentery of the segment in which it is made. I have also tried the proposed method of fixing the attached borders, using the short continuous Lambert suture as recommended by Robinson. This plan certainly shortens the time spent over the operation and seems to give a very good result, at least in the dead bowel. As the base of the triangular space is very little under one-third of an inch across and the rising layers do not come together for nearly three quarters of an inch, the sutures involving these layers on either side are necessarily when first placed further apart than at their insertions in the other segment, but owing to the looseness of the mesenteric layers at this point they turn in and fit accurately when tied.

As has been indicated, the great theoretical advantage which lies in the principle suggested is in the fact that at every point in the sutured circumference there is peritoneum on one or both sides, thus allowing no more danger at the attached borders than at any other part of the divided edges. To this I venture to add the practical advantages of adaptability to any form of stitching preferred by the operator and rapidity of execution, for not only are the stitches easily applied, but the time spent in securing the mesenteric regions is at the same moment spent in suturing a corresponding length of the whole circumference.

West Dulwich S.E.

A CONTRIBUTION TO THE ANATOMY OF THE PERITONEUM

By FRED J. SMITH, M.D. OXON, F.R.C.P. LOND.,
SENIOR PATHOLOGIST TO THE LONDON HOSPITAL.

C. MANSELL MOULLIN, F.R.O.S. ENG.,
SURGEON TO THE LONDON HOSPITAL,

AND

ARTHUR KEITH, M.D. ABERD., F.R.O.S. ENG.,
SENIOR DEMONSTRATOR OF ANATOMY TO THE LONDON HOSPITAL
MEDICAL COLLEGE.

THAT the two following extraordinarily rare cases should come under observation within six weeks of one another in the post-mortem room of one hospital is an illustration of the manner in which pathological curiosities seem to occur in groups.

CASE 1—A man was admitted to the London Hospital on Dec. 2nd, 1898, with signs of acute peritonitis. Laparotomy was speedily followed by death which occurred on Dec. 5th. On opening the abdomen post-mortem purulent peritonitis was found with a feculent smell suggesting perforation of the gut. Turning over the intestines in search of the wound Dr. F. J. Smith became aware of a dense, hard, fibrous ring, through which a mass of small intestine seemed to have passed. More careful examination led to the localisation of this ring. It was situated just at the lower end of the ascending colon, nearly opposite the cæcum, an inch or so from its inner border. The ring itself was very hard and definite. It was about two inches in diameter with a complete and uniform circumference. Before the herniated gut could be withdrawn the ring required to be freely incised, as soon as this incision was made the operator was able to withdraw an incarcerated ball of small intestine of about the size of a large orange! There were no signs of strangulation at all, but a perforation was found at the neck of the mass, due apparently to attrition against the

hard unyielding ring of the sac. This was the cause of the peritonitis and cleared up the case from a clinical point of view. The ring and sac were cut out and are now in the museum of the London Hospital.

CASE 2—A man, aged 20 years, was admitted into the London Hospital for fracture of the spine on Jan. 11th, 1899. He was in perfect health till the time of the accident and the abdominal condition was purely incidental with no bearing or influence upon his case. The patient died on the same day. On opening the abdomen and lifting the omentum it at once became apparent that there was an unusual condition of things to be investigated. The small intestines, instead of being loose and moveable upon one another, were found to be enclosed in a large sac with a thin peritoneal covering in front of them so that the coils could not be actually touched or individually separated. The ascending colon was situated a little to the left of the mid-abdominal line and had almost the whole of the small intestine lying to the right of it. Investigation showed that this peculiar relationship was due to the fact that the small gut—almost the whole of it—had slipped through a hole at the lower and inner margin of the ascending colon situated in precisely the same spot as in Case 1. The margin or ring of the cavity thus formed was very different in condition in this case from that of Case 1. It was definite and defined enough but very thin, membranous, and lax, and had exerted no strangling or incarcerating influence on the contents of the sac, it was so thin and so easily continuous with the mesentery—i.e., without definite change of feel or struc-

ture—as to be incapable of removal. After passing through this ring the small intestine had insinuated itself upwards and downwards along the whole length of the ascending colon and cæcum and appendix in the space ordinarily termed retro-peritoneal, removing them entirely from their usual position and relations on the right of the abdominal cavity and lifting them bodily to or beyond the middle line. The ring and tissues of the sac were so thin that Dr. F. J. Smith is unable to state whether between the herniated intestine and the omentum there were one or two layers of

CASES OF GASTROPLASTY AND
PYLOROPLASTY

BY THOMAS H MORSE, F.R.O.S Eng

THE very interesting and instructive paper by Mr Mayland in THE LANCET of April 8th, 1899, on the subject of Exploratory Operations upon the Stomach for Obsolete Gastric Symptoms marks another distinct advance in abdominal surgery—namely, that it should be considered justifiable to explore the inside of the stomach for diagnostic purposes. Doubtless many of the cases which have hitherto been treated medically will in future be cured by operation. The two cases which follow are illustrations of this and they also show that the stomach is very tolerant

of exploratory surgery

There was no special tenderness over the stomach and no tumor could be felt. I was inclined to the diagnosis of cancer of the pylorus. The same symptoms, however, continued without becoming any more and in December, 1897, I discharged with him the advisability of an exploratory operation, feeling sure that the case could not be one of malignant disease. In consequence he shortly afterwards entered the Norfolk and Norwich Hospital and was under the care of Dr Burton Kinnang. The diagnosis then made was that the stomach was bound down by adhesions and thus interfered with its functions, possibly the result of an old inflammation around a gastric ulcer.

Remarks by Dr SMITH—Though the existence of a pouch of peritonæum in the situation indicated by the above description is commonly recognised and reorganised, its development into a true hernia is very rare indeed and I cannot say to contain a true hernia. I have represented some features of clinical interest and I have consequently asked Mr Monro, to whom I am indebted for permission to publish the case, to make a few remarks upon it. Further references to the general question of the anatomy of the condition I have placed in the hands of Mr Keith whose authority on matters anatomical is undisputed. Mr Keith in addition to very kindly furnishing the excellent drawing of the preparation of Case 1 added the remarks which appear below.

for me to add to the excellent account which has been given by Dr R. J. Smith of Case I. The patient who was a rather feeble man with old standing spinal disease was admitted with the diagnosis of indurated appendicitis. There was a history of several previous similar attacks, each accompanied by vomiting, constipation, and pain and tenderness in the right iliac fossa. On this occasion the symptoms had commenced without any very obvious reason a few days before admission. There was definite tenderness with a sense of resistance in the right iliac fossa and the mass could be distinctly felt per rectum. After admission the symptoms subsided considerably, probably owing to the rest in bed and the careful dieting. The bowels acted slightly three times after enemas. The local tenderness diminished and at the end of 48 hours the patient felt so much better that he wished to leave and was with difficulty persuaded to stay. Then suddenly the next day, probably at the time that performance took place, general peritonitis set in with vomiting, abdominal tenderness and distension, and a quick, feeble pulse. Laparotomy was performed and the peritoneum was already injected and dull. The rug described by Dr R. J. Smith was felt at once and the finger nail inserted beneath it. This was instantly followed by a profuse discharge of a foul smelling brownish liquid similar to that which the patient had vomited on the last occasion. No attempt was made to divide the rug or withdraw it from the bowel. Todoliform gaseous was packed around and shot off with the general peritonitis as far as possible and a large drainage-tube then was inserted, but the patient rallied and died in a few hours from acute septic poisoning.

So far as I am aware the diagnosis of retro-cerebral hernia has never been made during life. In this instance it was definitely noticed that the size of the hernia varied. It diminished during the first two days and then increased again. The diminution was thought to be accounted for as the time by the release of impacted faeces under the influence of the enemas, and the subsequent increase by the extension of inflammation, for the difference was not too great to be explained in this way. Had it been possible to watch the case for a longer time this might have served as a clue.

*Remarks by Mr KEITH—*Case I without any doubt is the very rare hernia ilaco-subcostalis. The illustration explains that for it shows the position of the other two pouches in this region—the retro-cerebral and ileo-cerebral fossae. It is such is proved positively by the external iliac artery striking the inner wall of the sac. The hernia passes through the weak central part of the iliac fascia pushing the peritoneum in front of it. It is difficult to form a definite diagnosis of the nature of the hernia in Case 2, but it is probably an example of the very rare right diaphragmatic hernia described by Monaghan.

1 The LANCET March 4th and 11th, 1899.

BRISTOL CHILDREN'S HOSPITAL—The fifth

annual meeting of the supporters of the Connaught Home for Children, the institution established at Weston super-Mare in connection with the Bristol Royal Hospital for Children, was held on May 1st under the presidency of the High Sheriff of Somerset (Colonel Long). The report stated that during 1898 there were 297 children admitted. The accounts showed that there was a deficit balance of £104

richness of the blood. But although it has been surprising that this little patient's heart has shown so little signs of weakness after frequent and very considerable losses of blood he has suffered from palpitation and quickening of the heart's beat in the last few hemorrhages—the effect of nervousness, I believe. There has been no rise in temperature. Red bone marrow in tabloids and in the fluid form of elixir was tried with fairly satisfactory results. It is supposed to increase the production of red blood corpuscles and of hæmoglobin and it certainly improved my patient's appetite and brought him round much quicker after a severe hemorrhage than had been the case when it was not used. It does not seem to have any effect on the bleeding, but it does seem to be a most useful food and stimulant to eating while bleeding is going on. This was found also to be the case with a little child, also a "bleeder," under my care at the Lincoln County Hospital.

Lincoln

A NOTE ON X RAYS AND COLOUR BLINDNESS

By SYDNEY STEPHENSON, M.B., F.R.C.S. EDIN.,

OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL AND TO THE NORTH EASTERN HOSPITAL FOR CHILDREN,

AND

DAVID WALSH, M.D. EDIN.,

PHYSICIAN TO THE WESTERN SKIN HOSPITAL AND HONORARY SECRETARY TO THE ROENTGEN SOCIETY

FROM time to time sensational reports have been published as to the effects of the Roentgen rays upon various defective conditions of the eye. It was asserted, for instance, that cases of blindness had been relieved by the aid of the focus tube. In the hands of competent observers, however, the results of similar experiments have proved negative. The fallacy of the original observations may have lain in the fact that they dealt with cases of hysterical blindness—that is to say, with patients who might profess themselves cured under any novel plan of treatment. Or again, the blindness may have been due to opacity of the cornea or of the lens, whereby ordinary light would be excluded but no resistance would be offered by the opaque tissues to the passage of the Roentgen rays. A reference to some of the early literature on the subject shows that none of the alleged cases stand the test of critical examination.

Professor Muriati of Milan investigated five cases. One of congenital and two of acquired blindness, and two of light perception without sense of form. The two latter saw the glimmer of the screen and one of the two could count the shadows of the bones of the hand although unable to distinguish the form of keys, the three others saw nothing.

It has lately been claimed that the return of colour blind persons were acted upon strongly by the Roentgen rays. In order to test this assertion four colour blind children were subjected to the rays emitted from an ordinary bianodal focus tube attached to a 12-inch coil working at nine inches. The children were two of them aged eight years, one nine years, and the fourth 11 years and of good intelligence. Their colour sense was defective in red green and their form-sense was normal. Perception of light and form proved normal when tested by the screen enclosed in a bellows fluoroscope. When the children looked steadily at the brilliantly lighted tube they showed no signs of photophobia. They all recognised objects, such as keys, when held against the bare tube or against the screen. The after-phosphorescence of the tube was seen by all of them, as well as the greater intensity of the area in front of the anti-cathodal plane. Lastly, there was no sensation of light when the eyes were shut and bandaged and the children put in front of the "live" tube at the level of the eyes. To sum up, there was no reason to suppose that the return of these four colour blind children reacted to the focus tube in any way differently from those of folk with normal colour sense.

ST MARY'S HOSPITAL

A CASE OF TETANUS TREATED BY THE INJECTION OF ROUX'S ANTI TETANIC SERUM INTO THE SUBDURAL SPACE, RECOVERY

(Under the care of Mr H. S. COLLIER.)

WE have reported recently several cases of tetanus in which the antitoxin has been employed, and we are able now to record two other instances in which this treatment has been resorted to. The case in the Royal Hants County Hospital is a good example of a severe case with a comparatively short incubation period—namely, seven days, the disease itself lasted only, about 48 hours, and although 20 cubic centimetres of antitoxin were injected, yet death ensued. In the other case the antitoxin was injected into the subdural space. In April, 1898, Roux and Barret¹ published the results of some experiments on tetanus which showed that if the toxin of tetanus has already affected any nerve cells the antitoxin is powerless against it, but if the antitoxin be injected into the substance of the brain at an early stage of the disease when the lower nervous centres only have been affected the antitoxin will render the higher centres immune to the toxin. The method was tried in Paris and recovery followed,² and in 20 or more cases in France this treatment has been followed. Major Semple, R.A.M.C., has recorded a case in which this treatment was followed by recovery.³ In the case at St. Mary's Hospital which is reported below the injection was made into the subdural space instead of into the substance of the brain, this is evidently less dangerous and is well deserving of more extended trial. In the present state of our knowledge all cases should be put on record. For the notes of that case we are indebted to Mr O. H. Suttor, late house surgeon.

A man, aged 27 years, was admitted to St. Mary's Hospital on Feb 25th, 1899, for difficulty in swallowing and stiffness of the lower jaw. 14 days previously, while chopping wood, he cut the tip of his left thumb. At the time he took no notice of it, though it seems to have been rather a severe cut. He continued his work as a coachman and stable hand. On Feb 20th, five days before admission and nine after the injury, he noticed a good deal of pain and stiffness in his chest which he attributed to cold. The next day he had pain in the abdomen which "seemed to draw his chest down on to his stomach." On the 23rd his jaw became stiff and there was difficulty in moving the muscles of his neck and head. On the 24th swallowing became difficult and opening the mouth almost impossible. On the 25th, being worse, he attended at the hospital and was admitted.

On admission the patient was in a very anxious state, he was quite unable to swallow solids and could only swallow liquids with very great difficulty. The body was very rigid and when voluntary movements were attempted they took a very jerky form. The sterno-mastoids were very rigid and stood out like bars on either side of the head. Lateral movement of the head was impossible. The masseters were strongly contracted, but on effort the jaw could be dropped so as to leave an interval of about half an inch between the upper and lower incisor teeth. There was a depression of the angles of the mouth with contraction of the corrugator supercilii, giving the typical facies. The recti abdominis were very rigid, the other abdominal muscles being less so, the pectorals and intercostals were slightly rigid. The limb muscles were relaxed. The knee jerks were exaggerated. While being washed he had a short, sudden, shuddering

¹ Annales de l'Institut Pasteur, April, 1898.

² La Presse Médicale, June 18th 1898.

³ Brit. Med. Jour., vol. 1, 1899, p. 10.

attached, but there were at this time no convulsions. On examining the local lesion it was seen that the left thumb pad became severely inflamed, the tip was in a very red state and in the discharges from it some more degenerated rods were to be found than had been before. The leucocytes were depressed with carbolic acid injections. That was the beginning of tetanus bacilli.

The patient was dressed and was found to be quite healed. The thumb pad had cleared up and was nearly healed. On the fifth day the patient's general condition was very good, he could open his mouth for quite an inch. The muscles as he lay in bed became quite relaxed, but on his attempting to sit up they became very rigid, he could just get his body into an erect position with his legs over the edge of the bed, but all the muscles of his back stood out very sharply, the muscles remaining soft and moderate in tension. On the 16th of the chloral was stopped altogether, there was no return of the symptoms. On the 30th the patient was sent to a convalescent home.

*Remarks by Mr. COLLIER.—*I have asked Mr. Stratton to add this to the list of published cases of tetanus treated with nitrochloroform serum and we consider the report valuable as a contribution to that list. Considered by itself it warrants no conclusion as to the value of anti-tetanic serum. The case was of the subacute type and only on the night of Feb 26th was the outlook very gloomy. Until the time of the subdural injection the degree of muscular spasms progressively increased but after the first injection the muscular spasms were relieved. Improvements went on in the muscles until those of the neck were well advanced. The diminution of the spasms of other groups of muscles was very gradual. I have to thank Mr. Pittman, the pathologist to St Mary's Hospital, for his very valuable counsel in the treatment of this case.

ROYAL HANTS COUNTY HOSPITAL,
WINCHESTER
A CASE OF TETANUS TREATED BY TETANUS
ANTITOXIN, DEATH
(Under the care of Mr Cyril Wace.)
For the notes of the case we are indebted to Mr John
English, house surgeon.

A man aged 22 years, was on April 6th, 1899 admitted to the Royal Hanley County Hospital with the history that on March 20th he fell from a ladder on to a spike casing and lacerated wound of his leg to the outer side of the anterior edge of the tibia. He was taken home and the wound was dressed up. On April 5th there was slight stiffness of the jaw and the back of the neck with some pain and he was admitted into the hospital at 8.30 p.m. The temperature was then 100° F. the pulse was 73, and the respirations were 22. The teeth were firmly clenched, but the patient could speak distinctly. There was stiffness of the muscles of the neck, but retraction of the head was not marked. The abdomen was hard and rather retracted. He coughed every few minutes, the cough each time being accompanied by common spasms, during which the angles of the mouth were contracted and the teeth were tightly clenched. He had been led on milk through a bag where a good deal of food was missing. The legs were not so rigid as the arms. The knees and ankles were found to be unclenched and separated from the body and were found to be underdone and the feet from the knee to the ankle washed and put on dry socks. The patient was placed on his back and the legs were bent from the hip joints to the knees to a quantity of food was given. The patient was kept from washing and was not allowed to get up. The patient was kept from walking and was not allowed to get up. The patient was kept from walking and was not allowed to get up.

GUTHRIE, HOUSE SURGEON

Chloroform having been administered Mr Collier made an incision in the right occipital region, curved and about an inch and three-quarters in length, exposing the bone which was cleared of soft tissues. The half-inch trephine was applied and the disc of bone was removed. The dura mater was exposed and punctured with a needle. A blunted needle attached to an anastomotic syringe was inserted and the opening was stopped with subcutaneous tissue. During this process the pulse rate was up from 70 to over 100, coming down again in a few minutes to 81. The wound was sutured over the opening. There was no change in the temperature or respiration during the operation. Two hours later the pulse rate was 120 and the respirations were 25. The patient passed a quiet night. The chloral was discontinued on March 2nd the muscles of the back were distinctly less rigid and the movements of the back were more free. The patient was as before. Spinalgia was more or less relieved and the muscles of the neck were sufficiently relaxed to allow the head to be supported on pillows. He was, however, very restless all the morning, during the afternoon he had periodic attacks of rigidity of the muscles of the hip and afternoon and at six o'clock was 101.7, the pulse being 133. After this the temperature fell steadily and at ten o'clock the next morning was 100.4. During the night spinalgia became normal. On the 3rd the abdominal muscles were rather more rigid than on the previous day and the limbs were quite relaxed, the symptoms subsided and the patient was very hard. The lumbar spine was very fixed. Speaking and swallowing were no longer followed by perspiration. On the 4th the temperature was 99.4 and the pulse was 112, the muscles of the neck were less rigid so that he could move his head from side to side and could lie on his side with comfort. The masseter were still and the mouth could not be opened for more than three-quarters of an inch. There was no marked rigidity of the cervical column, the neck being relaxed still and as in one place, there

20 cubic centimetres of tetanus antitoxin were injected into the right flank. The patient slept at intervals, moaning in his sleep and perspiring a great deal, occasional spasms were brought on by coughing. He was fed at first by a spoon, but as swallowing became more difficult rectal feeding was resorted to. At 1 A.M. on the 7th the cough was more troublesome, the patient expectorating thick tenacious phlegm streaked with blood. At 4.40 A.M. he had a severe spasm lasting half a minute. At 2 A.M. the temperature was 100.2°, the pulse was 110, and the respirations were 28. Three minims of morphia were injected hypodermically. At 4 A.M. the spasms were more frequent and severe, the face being cyanosed, there was slight bleeding from the left nostril and the mouth was open during sleep. At 6 A.M. the temperature was 101°, the pulse was 138, and the respirations were 30, he was perspiring greatly. At 9 A.M. he was about to have a second injection of antitoxin when he became much worse, the pulse was very feeble and the breathing was difficult. The cyanosis passed off and pallor came on, and the patient died at 9.45 A.M. The last spasm occurred about five minutes before death, it was not severe and there was no opisthotonos or arching of the wrists. The temperature after death was 99°. There was an inquest, but unfortunately no post mortem examination was allowed.

To summarise the above case, the injury occurred on March 29th, on April 5th the onset of tetanus took place, on the 6th the patient was admitted into the hospital and tetanus antitoxin was injected, and on the 7th death supervened. The case presents one or two striking points. It was acute as regards onset and duration but the spasms were not at any time very marked. The head was held stiff and slightly retracted, but at no time was there opisthotonos or anything approaching the "head heel" position.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Rheumatic Pericarditis—Allaptonuria

A MEETING of this society was held on May 9th, the President, Mr BRYANT, being in the chair.

Dr J. POYNTON read a paper on Rheumatic Pericarditis. He said that his microscopic investigations supported the views expressed by Dr Lees and himself in two papers read before the society in June, 1898, and were a further contribution to the pathology of rheumatic dilatation. A brief allusion was made to the two papers upon acute dilatation in rheumatism and chorea and to the subsequent discussion. The patient from whose heart sections were made was a youth, aged 15 years, who was suffering from rheumatic pericarditis. During his last illness there was clinically progressive cardiac dilatation. At the necropsy the dilatation was found to be extreme although there was little valvulitis and only plasitic pericarditis. The microscopic investigations showed morbid changes in the vessels, interstitial tissues, and muscle of the heart-wall. These changes were general and not especially localised in the neighbourhood of the inflamed pericardium. Two of the clinical features were especially dwelt upon, one the extreme dilatation, the other the occurrence of Dr Roth's sign with the absence of pericardial effusion. The following reasons were given in support of the view that the myocardial changes were concurrent and not secondary to the pericarditis: (a) dilatation might occur without pericarditis and therefore it was unlikely that the myocardial changes were secondary to pericarditis when pericarditis was also present, (b) microscopic evidence pointed to the changes in the heart wall being general and not localised to the surface, and even in early pericarditis numerous foci of inflammation were found deep in the heart-wall, (c) the hypothesis of a rheumatic toxin probably of bacterial origin favoured the view of a simultaneous infection, when all parts of the heart were found diseased after death, and (d) though the post-mortem appearances of pericarditis were far more obtrusive than those due to changes in the myocardium, it did not necessarily mean that they were more frequent or had a greater significance. The anatomical characteristics of the pericardium

probably favoured a free reaction to the rheumatic poison, the firm cardiac wall probably allowed less reaction, yet it might be much affected by the toxin. Attention was directed to the marked dilatation which might occur in rheumatism with comparatively slight clinical symptoms. It was pointed out that even in acute and fatal cases of rheumatic carditis the changes in the muscle, though definite, were not extreme, whereas in other conditions—for example, "fatty heart"—the myocardial changes might be extreme and yet there be no obvious dilatation. Dr Poynton suggested that the explanation lay in the complexity of such a tissue as the cardiac muscle. It was liable to diverse pathological changes which probably had different interpretations. Some of these changes might be extremely destructive to the vital properties of the muscle and cause death from syncope with but little dilatation, others might pervert or impair the function of the muscle, and death occur with marked dilatation. The myocardial changes in rheumatism were not so gross as in cases of "fatty heart," yet the first definite clinical symptom of the latter might be sudden death, and therefore in rheumatism with less severe myocardial changes the clinical symptoms might not be urgent. The reparative processes after an attack of carditis were considered with especial reference to those taking place in the myocardium. Finally, allusion was made to adherent pericardium and the condition of the myocardium in those cases of morbus cordis in adults in which the symptoms far exceed the physical signs. Microscopic sections were shown in support of the statements made in the paper, with explanatory sketches by Dr A. W. SANDERS.—Dr D. B. LEES said that the paper afforded valuable evidence on several controverted points. First of all it confirmed Dr Herringham's contention that the limits of the cardiac dulness could be made out with accuracy by percussion as verified by post-mortem observation. Secondly, it confirmed the possibility of dilatation of the heart to an even greater extent than was shown to exist in living patients by percussion in the paper which was read by Dr Poynton and himself last year. At the time the paper was read some scepticism was expressed whether such extensive precardial dulness could be due to dilatation alone and was not due to pericarditis. The necropsy on Dr Poynton's case revealed greater dilatation than was indicated in any of their cases and there was no pericardial effusion. The importance of recognising that such dulness might be due to extension of the area occupied by the heart itself was very great, as he knew of several instances in which danger had occurred from an attempt being made to incise the pericardium in cases of dilatation under the belief that the heart was embarrassed by an effusion. Thirdly, the paper showed that Roth's sign was not conclusive of the presence of effusion. This had been maintained by Dr Lees at the discussion on heart disease in childhood at the Edinburgh meeting of the British Medical Association and it then received the support of Sir William Broadbent. The condition of the myocardium had been neglected, but there was no doubt that it might be affected independently since the changes found were situated throughout the muscle and not just under the epicardium or endocardium. He believed that in many cases of mitral stenosis or pericarditis which went down hill it was the muscular condition which was responsible for the fatal result.—Dr JOHN BROADBENT said that one of the cases to which Dr Poynton had briefly referred seemed thoroughly to bear out his contention as to the independent development of myocarditis. The patient had recurrent rheumatism and died during the second attack, when there were found recent interstitial change and also fibroid patches in the muscular substance probably dating from the previous attack of rheumatism. Assuming that the changes were due to toxins it was curious that in cases of diphtheria or enteric fever where dilatation of the heart occurred interstitial changes were not, he thought, met with and he suggested that this might be due to the toxins being produced in the heart itself in the case of rheumatism.—Dr T. J. McOLAGAN agreed as to the important part which there being a similar change in the voluntary muscles ought not to be overlooked and he thought that the abundant formation of lactic acid in rheumatism pointed in this direction.—Dr T. BARLOW mentioned the case of a girl, 15 years of age, who was under treatment for acute rheumatism. She developed pleural effusion which was tapped, giving her much relief. She died, however, and the heart was found to be greatly dilated,

Although there was neither endocarditis nor pericarditis a microscopic examination by Dr. Charles Wood Turner showed that there was extensive myocarditis. He quite agreed that the muscular change was not limited to the cardiac muscle, the protrusion in cases of acute rheumatism being comparable in some cases to that in erysipelas. The anatomic study of the intercostal and muscles of the forearm which was so striking in cases of acute rheumatism even without neuritis of the ulnar nerve were best explained on the ground of myositis. — Dr. FORSTNER, in reply, said he thought that there were two processes, toxic and reaccitive. The loss of muscular tone which occurred in diptheria as well as in rheumatism was a toxic process, while the interstitial changes which occurred later in rheumatic cases were part of the process of reaction. He was already investigating the state of the voluntary muscles in acute rheumatism.

Dr. ARCHIBALD GARNOD contributed a paper on alkaptonuria. He observed that although a very rare anomaly alkaptonuria possessed much interest both in the physiological and clinical aspects. The urine of alkaptonuric individuals darkened rapidly after it was passed, acquiring a deep brown colour. The change was much more marked on the addition of an alkali and was attended by absorption of oxygen. The urine reduced Fehling's solution with the aid of heat and ammoniacal silver nitrate solution in the cold. It was optically inactive and the reducing substance did not ferment. Fabrics moistened with the urine became deeply stained on exposure to the air. The reducing action of the urine might cause the condition to be mistaken for glycosuria. The history of alkaptonuria dated from an observation of Böttcher in 1889, but a case almost certainly of this nature was read to the Royal Medical and Chirurgical Society by Dr. J. Mares in 1822. Dr. Garrod had only been able to find 24 examples in a table together with seven additional cases embedded in a table recorded examples of alkaptonuria which were hitherto unrecorded. For the notes of five of these he was indebted to Dr. Ray, as also for some specimens of urine.

Alkaptonuria was usually congenital and lifelong and was apparently without injurious influence upon the health of the patient. The great majority of the patients were males, of the congenital cases a considerable number had occurred in brothers and sisters. In a few instances temporary alkaptonuria had been observed. Böttcher isolated from the urine of his patient a substance which he called "alkapton-catechuic acid" and was thought to be the abnormal constituents present. Kirk isolated and analysed a crystalline acid which he called uronic acid. Marshall gave the name of glycosuria acid to a substance obtained from the urine of an alkaptonuric patient homozygous for hydroxyphenone acetic acid, which substance had been met with in all subsequent cases in which it had been sought for. Happen to uronic acid homozygous acid had not hitherto been detected in any recorded cases except those of Kirk, but as a rule its presence did not appear to have been excluded. Observations by Wolkow and Baumann seemed to show conclusively that tyrosin was the parent substance of homozygous acid in the organism and they regarded it as probable that the latter was formed in the intestine by the action of a special micro-organism. Later observations, although they did not directly negative this suggestion, had failed to lead to any support. It was at one time supposed that alkapton urines were extremely degenerated, but later observations did not support this observation. Dr. Garrod had had no support of examining the urine of five alkaptonuric individuals. Case I was that of an infant kindly transferred to his care by Dr. Fockler. The staining of the napkins was noticed on the day following birth. The patient was old and was in good health. The faeces were now 15 months in all previous cases in which they had been examined, to be free from homogentisine acid. A bacteriological examination made by Dr. Dreyfuss led to no conclusions. The urine had all the properties of the normal urine. The urine was brought to the hospital on account of the peculiar colour of the urine. Owing to the daily excretion could be as yet carried out but uric acid was found to be present in undiminished quantity.

urine and was extracted in the form of its lead salt by Volkow and Baumann's process as well as by a simpler process recently described by Dr Garrod. Analytical figures were given showing that the lead salt obtained was lead homogeneous and from it the free acid was prepared and its melting point determined. A further search for the uronic acid of Alk was attended with a negative result. Case 2.—The patient was a school boy, aged 14 years, whose sister was also alkaptonuric. Her case was described by Dr Armstrong and Dr Walter Smith in 1882. The boy was a patient under the care of Dr C E Baker. From the urine of this patient also homogeneous acid was extracted by both the processes above referred to. Here also the search for uronic acid was attended with a negative result. Cases 3, 4, and 5.—The urines of these patients who were two brothers and a sister, were kindly given to Dr Garrod by Dr Ray. The specimens were small in bulk and had been kept no less than eight years. It was, however, still possible to demonstrate the presence of homogeneous acid in two of the specimens. The bulk of the third specimen was unfortunately lost, and the result was therefore inconclusive as to the presence of homogeneous acid, although there was good reason to believe that this substance was present in this case also. The observations described in this paper tended to support the view that the presence of homogeneous acid in the urine was the essential feature of alkaptonuria and that uronic acid, when present, was of the nature of a by-product of the abnormal metabolic process. A complete bibliography of the literature of alkaptonuria was appended to the paper.—Dr F RAY said that he had been fortunate enough to meet with five of these cases and he had been very glad to hand them over to Dr Garrod whose paper, he thought, would be a classified one. It was curious that the passages of this substance did not affect the general health of the patients and did not even affect the colour of the urine at the time it was passed. A somewhat parallel condition as regards the uronic acid was present in the case of the patient who suffered from incontinence unless a collection of crystals formed in the bladder. There was no evidence of a metabolic origin in either case. It was of great importance that the condition should be recognised, as the reducing action of the urine on Fehling's solution might lead a life insurance examiner to think that sugar was present.—Dr J MACGILL said that he had only come across one case of this kind, but there were many other forms of alkaptonuria in which the urine turned alkaline when it became alkaline. One example was carbamides, in which the urine passed was not dark till it became alkaline. He mentioned the case of a man with cystitis and pyrophosphorus whose kidneys was incised and a *straw* formed in the loin. The man developed carbamides and while the acid urine passed through the fistula was normal in this, the alkaline urine passed by the urethra was dark. He wondered whether Dr Garrod could tell him the composition of the pigments. Dark urine was also seen in cases of poisoning by nitrobenzol and antifebrin which contained the benzene group and the amino group respectively.—Dr F G HOPKINS said that he had to examine 3000 specimens of morbid urine and only one had shown definite signs of alkaptonuria, although in two others there was a vague darkening which remained unexplained.—Dr GARROD, in reply, said that he did not know the nature of the pigments. He thought that the name "alkaptonuria" should be restricted to those specimens which not only turned dark when alkaline but also reduced Fehling's solution.

Librarian Dr Sidney Martin Honorary secretaries Dr James Calvert and Mr Frederick O Wallis Honorary Secretary for Foreign Correspondence Dr William Ewart Council Dr William H Allohin, Mr William H Baker, Mr William H Battle, Mr Stanley Boyd, Dr Henry A Calley, Dr Walter S Colman, Mr J W Dennis Dallaway, Mr Alban H G Doran, Dr J Kingston Fowler, Dr George W Isaac, Dr Robert Maguire, Mr John H Morgan, Dr J Baldwin Nias, Dr Humphry D Rolleston, Mr Morton Smale, Dr Frederic J Smith, Dr Herbert R Spencer, Mr Charters J Symonds, Dr Arthur F. Voelcker, and Dr Edward G Younger

Subsequently an ordinary meeting was held, Mr OWEN being in the chair

Mr BRUCE CLARKE read a paper on Encysted Vesical Calculi, with an account of 27 cases. After referring to an earlier paper in which six similar cases had been described by him in St Bartholomew's Hospital Reports for 1891, vol xxvii, Mr Bruce Clarke pointed out that in these cases where the stone was fixed to the bladder wall the usual symptoms of stone were absent. Hematuria and pain rarely occurred and cystitis was usually the only symptom with which the cases were associated. At an early stage the symptoms they presented were assumed to be due to some other cause and the stone was often only detected when the bladder was opened. In half the cases which were described in the paper this was the case. The exact position of the stone in the bladder wall varied considerably. Some were embedded in the prostate and some lay loose in cysts in other parts of the bladder, but these cysts were usually found near the base. One instance was recorded where the patient was castrated in consequence of an enlarged prostate and after death a stone was found embedded in its substance. In others the bladder wall was so thinned where the stone lay that inflammation and in some instances suppuration of the surrounding parts occurred. Mr Bruce Clarke showed that most of these cases occurred in individuals between 60 and 70 years of age and pointed out the need for exploring doubtful cases of cystitis which did not yield to ordinary methods of treatment. The PRESIDENT said that Mr Bruce Clarke's experience must be unique as these cases were very rare. He was interested to hear of the frequency with which the cystoscope gave negative results. He fully agreed that in obscure cases of cystitis the correct plan was to make a suprapubic exploration and remarked that the use of a vaginal speculum was often of great assistance. Mr SWINFORD EDWARDS said that he had only met with two cases out of 200 of vesical calculus. The enlarged prostate often interfered with the introduction of the cystoscope, but when it could be introduced he would expect it to be of value. Attempts to catch the end of an encysted stone and crush it *in situ* or drag it into the bladder were as a rule inadvisable, it being best to reach them through a suprapubic opening. In one case, however, he was able to dislodge a stone which was encysted above the pubes and crush it when it had been displaced into the bladder. Mr BUCKSTON BROWN said that calculi lying in the post-prostatic pouch were not to be confounded with true encysted calculi, those actually embedded in the walls of the bladder, the surgical treatment of the two classes being entirely different. Mr P J FREYER said that he had only met with 20 cases of this kind out of 2000 cases of vesical calculus. Mr BRUCE CLARKE, in reply, said that the cystoscope was of use in some of the cases, but in many the stone was so completely embedded that it could hardly be seen or felt when the bladder was opened. He agreed that it would be best to crush the stone *in situ* when the opening was large enough. In all of his cases the stone was actually embedded and not lying in the post prostatic pouch.

Mr FREDERIC EVE read a paper on Two cases of Resection of the Large Intestine with Recovery. Case 1 was that of a man, aged 46 years, with a large left scrotal hernia which had been strangulated for three days. The sac contained a knuckle of the transverse colon which was gangrenous. A glass tube was inserted into the intestine and the latter was attached to the wound. Five weeks later the intestine forming the artificial anus was brought out of the abdomen after opening the peritoneum, resected, and sutured. The intestine was returned and the abdomen closed. Primary union and recovery without complication ensued. Case 2 was an example of carcinoma of the descending colon, for which Mr Eve was indebted to Dr F J Smith. A woman, aged 47 years, had suffered with pain in the abdomen, vomiting, constipation, and occasional melena for seven months. A tumour in the

left loin had been noticed for some months. The constipation culminated in an attack of obstruction during which the first operation was performed. This consisted in bringing out the tumour with several inches of healthy bowel and fixing the bowel to the parietes. The bowel was drained by the insertion of a glass tube. 10 days later the protruding portion of the bowel was removed and the mesenteric edges of the divided ends were brought together with sutures. After allowing an interval of a month for the inflammatory effusion around the wound to become absorbed an incision was made around the artificial anus down to the peritoneum. The latter was not opened but was separated from the parietes for about two inches all round the protruding bowel. The free ends of the intestine were refreshed and brought together with Lembert's sutures. The parietes were then closed over the bowel. The wound was completely healed three weeks after the operation. At the present time the patient appeared perfectly well and had suffered no inconvenience. Mr EVE was of opinion that in these and similar cases the bowel should be drained even although only moderate symptoms of obstruction existed. He thought that for the large intestine at any rate suture was safer than the use of Murphy's button except when rapidity was necessary. Case 2 was published especially to draw attention to the merits of extra peritoneal resection and suture for artificial anus as the safest method. It was introduced by the late Mr Greig Smith. This operation was attempted in Case 1 but had to be abandoned owing to the extreme thinness and friability of the peritoneum. This was probably due to stretching of the membrane from the presence of a large hernial sac in its neighbourhood. Mr W H BATTLE agreed that it was inadvisable to resect the bowel at the same time that obstruction was relieved. He remarked that it was not always possible to get the affected portion of the bowel to the surface, especially if there was much distension. He used lateral anastomosis to end-to-end anastomosis and preferred careful suturing to the use of bobbins. Mr F O WALLIS agreed that suturing was better than the use of Murphy's button or bobbins in the case of the large intestine but thought that in the case of the small intestine they were sometimes of use. Mr EVE, in reply, said that in resecting the growth he purposely cut away more of the mesenteric side of the gut in order to lessen the formation of a spur.

Mr PEARCE GOULD brought up the report of the committee, consisting of Mr Marmaduke Sheld, Mr Stanley Boyd, and himself, on the case of supposed cure of Sarcoma by Coley's Fluid reported by Mr Battle. After considering the clinical record and Mr Shattock's report and examining some sections they were of opinion that the pathological appearances were not conclusive of sarcoma and that the possibility of the lesion being a syphilitic one was not excluded.

OBSTETRICAL SOCIETY OF LONDON

Fibroid Tumours—Exhibition of Specimens

A MEETING of this society was held at 20, Hanover square, W., on May 3rd, Mr ALBAN DORAN, President, being in the chair.

The PRESIDENT read a paper on Fibroid of the Broad Ligament weighing 44½ lb (20 kilogrammes) removed by enucleation, recovery, with table and analysis of 39 cases. The patient was 28 years of age and her last confinement was six years before operation. Shortly afterwards a tumour developed in the left iliac fossa, three years later it became impacted in the pelvis. Dr Ward Cousins succeeded in pushing it into the abdominal cavity, this gave great relief, but the tumour grew rapidly and albuminuria and anasarca set in. The catamenia remained normal throughout. The tumour grew in such a manner that the lower ribs were not stretched out but pushed back behind it. In order to spare as much blood as possible the ovarian and round ligament vessels were ligatured proximally and distally, the capsule was divided between the ligatures which were then tightened, and lastly the incisions in the capsule were united, so that after its complete division horizontally and the securing of the cervix uteri the tumour was enucleated without loss of blood. The cut edge of the capsule was drawn together with a purse-string suture its cavity being packed with iodoform gauze. The serennecid was left on the cervix as it answered well its purpose and lay separated by the capsule

Dr HUBERT HOBERTS read notes of a case of a large retro-peritoneal fibroid undergoing suppuration. The patient was a married multipara, aged 50 years. There was a history of an abdominal tumour for over 13 years. Suppuration ceased eight months ago since which date the tumour had lost flesh and the tumour had increased in size. A large tumour (which, including the pus weighed 33 lb.) was removed up to the external carotid. The fundus uteri could be felt just above the symphysis. The cervix could not be reached per vaginam. At the operation (performed by Mr Meredith) adhesions were found between the tumour and the peritoneum. The tumour contained 13 ounces of odorous pus, it was removed by enucleation together with the body of the uterus and the pedicle was treated extra peritoneally. The patient 19 days later was making an excellent recovery. The tumour grew steadily in the broad ligament and had only slight adhesion to the uterus—Dr ERIC MACLEAY referred to a specimen of broad ligament myoma which he had removed and exhibited to the society. The patient was 45 years of age and the menstrual function had been normal since the birth of her only child. Some seven years previously she had been conscious of a pelvic swelling and of "bearing down." During the last two years the tumour had increased much in size. A broad ligament myoma, weighing 14 lb., was enucleated from the left side and its pedicular attachment to the upper part of the uterus was ligatured and divided. Hemorrhage due to the rapid retraction of the pedicle necessitated the removal of the uterus and its appendages. The patient made a good recovery—Mr BRUCE SMITH asked what was the position of the uterus in the case reported by Dr Roberts. In all the cases of intra-ligamentous tumours which had come under his own observation the uterus was pushed or drawn up high in front of the tumour and in many cases that organ could be felt through the abdominal wall.—The PRESIDENT, in reply, mentioned these more cases of fibroid of the broad ligament. Dr HOBERTS, in reply, said that in the case reported the uterus was quite small and displaced forwards and upwards close behind the symphysis. He registered that none of the cases in degenerating fibroids could throw further light on the suppurative process.

The following specimens were shown—
Dr PUTNAM (Birmingham) (1) A fetus enclosed in the Amniotic Sac only and (2) a cyst of the broad ligament.
Dr GALLIE, Ruptured Tubal Pregnancy.
Dr ADAMS, Ruptured Tubal Pregnancy.
Mr TACCHET Two cases of Bilateral Tuberculous Pso-

It is a means for the Relief of Pain

Vice-President Mr. PLATTON, being in the chair
Mr. LOCKWOOD read a paper on Antichromy for the Rebel
of Pain, Memorial of Synonymal Fritzes, Loose Bodies, and

[illegible]

instances the affection had been met with in women and twice in children under 10 years of age

Mr HERBERT ALLINGHAM had operated in 50 cases for one or another of the various conditions mentioned in Mr Lockwood's paper. The series included 18 cases in which the internal semilunar cartilage was excised and 13 in which the dislocated cartilage was sutured in position, and 11 cases in which loose cartilages and three in which osteophytes were removed. In one case of chronic rheumatism the joint was drained and in three cases although nothing definite was found to explain the symptoms the latter were relieved by arthrotomy. In Mr Allingham's opinion the most satisfactory view of the interior of the knee joint was obtained by a longitudinal division of the patella through an incision beginning at the upper part of the joint and continued downwards into the ligamentum patellæ.

Mr W J WALSHAM had during the last 18 months also operated upon about 20 cases of the kind under discussion without any mishap. He insisted upon the importance of careful preparation of the patient for such operation and thought it very advisable to keep the knee fixed on a splint for a week if possible beforehand. He strongly advocated transverse division of the patella as the best means of freely exposing the knee joint. Mr Walsham agreed that the symptoms of a dislocated semilunar cartilage were often not such as were described in the text-books and might consist of little more than a crack or snap during the movements of the joint. In the treatment of such cases after operation he advised that movement should be commenced at the end of a fortnight and that the patient should be allowed to walk at the end of three weeks.

Mr JACKSON CLARKE referred to the case of an athletic man who had had pain in a knee-joint for four years originating in a sprain received at golf. The symptoms were so severe that at first it seemed likely that the joint would require to be opened. Mr Clarke, however, first tried the effect of a support which prevented lateral and rotatory movement at the knee. This measure proved successful and enabled the patient to play football, polo, and other vigorous games. At the end of a year the apparatus was left off and the patient had no further trouble.

Mr RAYMOND JOHNSON referred to a case in which suppuration in the knee joint followed an operation for the removal of a semilunar cartilage. He at once drained the joint by free lateral incision and recovery followed with a very fair amount of movement. He believed the infection of the joint took place from the skin and was in part accounted for by the fact that at the time of the operation there was still a good deal of fluid in the joint. It was certainly much safer in these cases to delay operation until the attack of synovitis had subsided. A question was asked as to the probable nature of some cases of diffuse villous synovitis in which there were no definite evidences of osteo-arthritis. Mr Johnson also referred to the comparative rarity of the origin of loose cartilages in joints resulting from detachment by injury of a portion of the articular surface.

The CHAIRMAN congratulated Mr Lockwood upon the success with which he had followed up such a considerable series of cases. The long villous processes found in the synovial membrane of some cases of rheumatoid arthritis were microscopically identical with the villous processes normally found in the rabbit's knee and which had masses of "mucoid" material projecting from them.

Mr Lockwood replied

but also in the ranks of the medical profession. Owing, however, to improved social conditions amongst the lower classes and better hygienic conditions generally epidemics of typhus fever have practically disappeared and even an outbreak such as the one now described was an exceptional event. Accurate information regarding the prevalence of the disease in the city previously to the adoption of the Notification Act in 1879 was impossible, but Murchison gave the figures of those admitted to the Edinburgh Royal Infirmary during the years 1862 to 1871, and these amounted in all to 2824 cases—a small proportion only of those affected. During the 10 years 1880-89 there were 355 cases notified and during the last nine years 127 cases were reported. If, however, the number in the recent epidemic (79) was excluded the average number of cases per year from 1890 to 1897 was only six. It was of interest to note the diminution in the death rate in recent years. From 1880 to 1889 the mortality was equal to 28 per cent, while in the subsequent nine years it had sunk to 14 per cent. The following was a brief history of the recent epidemic. In the first week of October, 1898, four doubtful cases were admitted to the City Hospital. All of these patients came from one neighbourhood (Simon square) and resided within 100 yards of each other. In the following week three other cases were admitted. The number of admissions steadily increased during the remainder of October and November, but decreased again in December and was followed by the disappearance of the disease completely by the middle of January of this year. The presence of the disease in many towns and districts of Scotland afforded sufficient grounds for maintaining that the infection was certainly introduced into the city from without and it had probably existed for several weeks before it was recognised in October, as at this period several cases arose simultaneously in families where supposed influenza had existed previously. A man who had resided in one of the worst parts of the affected area died in the beginning of September from "pneumonia" and a "wake" was held for two days over his body. This was in all probability a case of typhus fever, for three of those who "waked" the body were ill with supposed influenza and still later three others suffered from typical typhus fever. The cases, with a few exceptions, occurred within a radius of a quarter of a mile and amongst families who were in constant intercommunication. Those cases which occurred out side this area were clearly traced to infection from this focus. Actual contact was proved in every case of those affected. Members of the patient's family might mix with other families on the staircase or outside the house apparently with impunity. The dissemination of the disease by actual contact was demonstrated by interesting examples in this epidemic. In one case 22 members of a single family caught the disease and seven of them died. It was proved also in this epidemic that the infection might be carried by fomites though they were not nearly so active as was generally believed. The means which ought to be adopted to prevent the spread of the disease were—(1) isolation of the patient in hospital, and (2) quarantining for at least 15 days of all persons living in the same house as, and all those who had been in close communication with, the patient. This was, as a rule, easily carried out amongst the class of people they had to deal with, provided some small compensation was given and means were taken to prevent their losing their employment. The houses themselves and their contents should be thoroughly disinfected.

Dr KER, after alluding briefly to the disease as it was described by Murchison and Moore, said that in three cases accurately observed in this epidemic the incubation periods were respectively 12, 13, and 17 days. At the beginning of the illness the temperature rose at once and usually reached its acme within three days. In this epidemic the rash was usually well out by the fourth day. Dr Ker then described fully the usual clinical features of the disease. In this group of cases the temperature was never less than two days in falling to the normal and in the majority of cases it took three days. The urine gave Ehrlich's diazo reaction in 15 cases which were examined and this showed how little reliance could be placed on the so-called test as a differentiation between enteric and typhus fevers. One patient suffered from the same disease six years previously. Two women went through the disease without interruption to their pregnancy. Nine deaths took place out of a total of 79 cases—equal to 11.39 per cent. Age had the greatest influence on the death rate. Of 24 cases under 12 years of age none died and of 35 under 20 years only one

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

Meeting of Intestine—Typhus Fever

A meeting of the Society was held on May 3rd, Sir JOHN LALOR presiding.

Dr KER exhibited the Intestines from a patient who had died of Typhoid Ulcers. The patient was a healthy woman and no dissection was required.

Dr KER exhibited the Intestines from a patient who had died of Typhoid Ulcers. The patient was a healthy woman and no dissection was required.

ROYAL ACADEMY OF MEDICINE IN

IRELAND

SECTION OF OBSTETRICS

The Samaritan Hospital for Women, Belfast.—Urbane

At 20 years of age and upwards there were eight deaths. Of these nine deceased cases were strong, well-developed men and five were distinctly alcoholic. As regards differential diagnosis from typhoid fever the best method to use when in doubt. Strong beer-tea and meat juices were used partly to replace alcoholic stimulants. The staple diet was milk supplemented in some cases by Benger's food. Cold water was given freely, also white fish, bread and milk, and eggs were allowed so soon as the temperature became normal. In about three-quarters of the adult cases and one-quarter of the children alcohol was required in doses of about half an ounce every two or three hours to each adult. Cardiac tonics were not found to be of much service. Hypnotics were required by about half the adults. Their early and free use was found to be very beneficial, and paraldehyde was those most frequently employed. No antipyretic drugs were administered. Even in cases where the temperature remained at 105° F. only frequent tepid sponging was employed. Each patient was only allowed one sheet and one blanket as long as his temperature remained high. Besides this any patient who passed his evacuations involuntarily was kept naked in bed in order to save exhaustion caused by changing the nightgown. The ward temperature was usually not above 55° during the day and 50° during the night. When a patient developed the crisis extra blankets were added to the bed and as soon as possible he was removed to a convalescent ward kept at an ordinary temperature. In all 16 nurses and four medical men had charge of the cases and none of these caught the infection. This immunity might have been in part due to frequent baths and plenty of open air exercise. Another precaution might have contributed to the health of the staff—that was the sponging twice daily of the whole body of each patient with Jeyes' fluid diluted with water. The patients and of an ointment of boric acid and menthol being used every few hours. In conclusion Dr. Kerr said that this outbreak was at least of average severity and that there had been no change of type since the days when the fever used to infect the city.—Dr. JAMES CAMPBELL said that when he was resident in the Royal Infirmary in 1865 there were 311 cases treated in the wards in 15 months and the mortality was then 12 per cent. At that time a large proportion of students and residents (including Dr. Carmichael himself) took the disease.—Sir JOHN BARRY (Kerr, Dr. ALEXANDER, Dr. JAMES DRAGBELL, ROBERTSON, and Dr. CHURCH also joined in the discussion.

A MEETING of this section was held on April 21st, Dr. J. W. KERR, the President, being in the chair. Dr. JOHN CAMPBELL read a paper entitled "Two Years' Work at the Samaritan Hospital for Women, Belfast." This hospital was founded in 1872 by the late Dr. W. K. M'Kendrick and the present building was erected in 1874 through the munificence of the late Mr. Edward Benn. In 1893 Mr. Forster Green generously added two cancer wards. The hospital contained 30 beds. Each patient brought a printed form signed by her medical attendant recommending her "as a fit person to receive gratuitous advice and treatment." This system worked well and there was the responsibility of consulting a hospital abuse on the members of the local medical profession. Patients to be operated on were well scrubbed with soap-and-water and wore boric compresses over the seat of operation for three or four days before being removed to the ward. The day before operation the region was well washed with soap-and-water, and finally washed with one in 1000 sublimate solution and covered by a compress wings out of the same. This pre-operation was repeated on the morning of the operation day. The operation was cleared by thorough washing, followed by sponging in warm water and again in soap-and-water. They were then put through the permanganate and sublimate processes in succession. Instrumental sponges were used.

used if a septic case had been recently handled. The gloves were boiled. Chloroform was given by funnel in smaller and in cases in which glaucoma had escaped into the abdomen. Drainage was used after draining in cases where much peritoneal fluid had been present and in cases in which pus had escaped. The current of opinion had now set in too strongly against drainage. A glass tube with a gauze wick was to be preferred and the bed-head should be raised. Sterilized gauze was the dressing used for most cases. Iodoform was used for wounds which were drained. During 1897-98 there were 44 instrumental operations performed in the hospital by Dr. Campbell with a mortality of 4 per cent. Before dangerous operations the patient and a near relative signed a printed form authorizing Dr. Campbell "to perform whatever operation he may think necessary." The President expressed his approval of these printed forms. He thought that gloves should be used in operations only when it was suspected that the hands could not be rendered completely aseptic. He did not agree with Dr. Campbell's opinion that all the dangers of chloroform were due to maladministration. When chloroform was administered gutta serena he had seen no ill effects. Dr. Campbell's mortality of 4 per cent was very satisfactory.—Dr. BARRY said that he had practically given up drainage. He believed that he did not believe there was any need for the printed form to be signed by patients about to undergo operation.—Dr. JAMES DRAGBELL agreed with Mr. Alexander's remarks about the printed form.—Dr. FERRIS said he was one of those who practised drainage but he never used a rigid tube. Dr. MOXER MANN read a paper on Uterine Cancer and its Treatment, in which he laid stress on the early recognition of this disease by local investigation as well as by microscopic examination of specimens removed by curetting in every instance of possibly adenomatous or cancerous disease of the uterus. He believed that that disease was primarily developed in the cervix in the vast majority of instances. Moreover, he held that it frequently remained localized there for a sufficient period to permit its complete and effectual cure by the timely amputation of the cervix, which, followed by the application of the actual cautery to the wound so produced, he regarded as the best method of treatment. In 31 instances in which the cervix was thus amputated, there was no mortality consequent on the operation, in one of these, however, the disease returned in the uterus four months subsequently. In five cases it returned there or elsewhere within a year, in 10 within two years, in one within three years, and in one nearly four years after operation. But on the other hand in 10 cases there was no return within a period of four years and in some there was no recurrence 10 years after the amputation of the cervix. For the relief of pain in cases of inoperable uterine cancer the recommended cauterium and orthotomy. To mitigate the fear of disfigurement he relied on terebinthine injections peroxide of hydrogen, and a 1 per cent solution of formalin. As local applications in open carcinoma he had experienced most benefit from the employment of celandine and methylene blue.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 18th, the President, Dr. BERRY, being in the chair. Dr. J. B. HALL showed (1) a microscopic Demonstration.—Dr. J. B. HALL showed (1) a small Dermoid Cyst of the Ovary in which there were three ovaries, the first containing hair the second teeth and bone, and the third a mucoid fluid, and (2) a Calculus removed six months after lithotomy.—Dr. BERRY showed a case of Ophthalmitis following removal of a patient suffering from a patient who had suffered from facial neuralgia. Dr. WILSON showed a patient who had recently had treatment of Uterine Cancer accompanied by a paper on the Operative Treatment of Cancer which he had had recently under treatment. Dr. Alexander discussed the relative propriety of the operations of supra vaginal amputation and of vaginal hysterectomy. While admitting that there was a very large body of modern opinion in favour of complete hysterectomy he

cited Schroeder, John Williams, and others who advocated supra vaginal amputation, and pointed out that the immediate mortality from hysterectomy was higher than from supra vaginal amputation, while the recurrence rate was no lower. The advocates of hysterectomy said that the high recurrence rate was due to the fact that hysterectomy had been reserved for more severe cases while supra vaginal amputation has been practised on the early cases. Dr Metcalfe then described the distribution of the pelvic lymphatics and expressed the opinion that it was impossible by vaginal hysterectomy to remove the whole of the diseased area together with the lymphatic glands, and consequently that if the disease had spread beyond the limits of the uterus recurrence was probable after either hysterectomy or amputation of the cervix.—Dr Rabagliati, Dr Wood, Dr Hall, and Mr Althorp discussed the paper and Dr Metcalfe replied.—Mr Alfia read a paper on Contagion from a Historical Point of View. He said that disease was in very early times considered to be transmissible by charms and ceremonies, some of which were still extant. Thucydides records the contagious character of the plague at Athens, B.C. 430, and about the same time Hermitippus, the comic poet, mentions the itch as transmissible. A little later Isocrates alludes to consumption as contagious and Aristotle has no doubt of the contagious nature of the plague. But the strictly medical writers in Greece before the Christian era ignore contagion. Aretaeus was the first medical author who recognised contagion at all, this was in the second century A.D. Bubonic plague could be traced back further than any epidemic disease, it was now possible to identify it in the sixth century A.D., when it pervaded the Roman Empire, Eastern and Western, for 50 years. According to Gibbon it depopulated the most flourishing countries, some of which have never recovered. For three months from 5000 to 10,000 persons died daily at Constantinople. At this time Mayrius looks upon it as decidedly contagious, while Procopius, another contemporary historian, denies contagion in strong terms. For a thousand years after this the same disease appeared at intervals in every country in Europe. The recognition of small pox by Rhazes in the tenth century was an important event in the history of epidemics, for though the disease had probably appeared long before it was not properly marked off by physicians. From that time measles, chicken pox, and ultimately scarlet fever, typhus fever, and enteric fever were gradually analysed and separated from one another. The belief in contagion was gradually placed on a firmer foundation. Rhazes does not lay much stress on it, though he admits that small pox and measles are contagious. He dwells principally on the great susceptibility of children and the less susceptibility of older persons. There were thus three lines of thought in ancient history in regard to epidemics—the idea of contagion, that of the patient's susceptibility, and that of a common cause for epidemics. These three theories still contended with one another.

LIVERPOOL MEDICAL INSTITUTION—A meeting of this society was held on April 27th, Dr Macfie Campbell, President, being in the chair.—Dr John Hay read notes of Three Cases of Pulsus Paradoxus. In the first the abnormal pulse condition was associated with the dyspnoea of acute bronchitis in a child, aged three years, and was only a temporary phenomenon. The second case was one of pericarditis with effusion complicated by serous effusion into the right pleural cavity, the removal of this fluid improved the pulse condition, but the pulsus paradoxus again became well marked without a reaccumulation of fluid in the pleural cavity. The third case was one of reversed pulsus paradoxus, the arterial pulsation in the vessels of the right side of the neck and right arm disappearing during expiration. It was observed in a man suffering from aneurysmal dilatation of the arch of the aorta. The cases were illustrated by pulse tracings and charts of the chest conditions.—Dr Bradshaw considered that the anacrotic character of the pulse in the last case was due to the percussion wave being largely lost in its transmission through the sac of the aneurysm. It was followed by a slowly advancing tidal wave. The increased anacrotism during expiration was to be explained by increased interference with the passage of the tidal wave.—Mr Frank T. Paul exhibited a patient upon whom he had performed Colotomy by a new method. The divided large intestine was conducted for some distance between the muscles of the abdominal wall and then brought

to the surface. This allowed of efficient control by a light horseshoe truss.—Mr Rushton Parker exhibited a boy whose Right Upper Extremity had been almost totally avulsed by machinery, necessitating the removal of the whole except a short piece of the clavicle. The subclavian artery had been torn across. The injection of saline solution into the veins acted very beneficially.—Dr Whitford exhibited a patient who had been more or less under his care and treatment for Lupus for a period of 17 years. The patient came of a very tuberculous family. Some of the scars as the result of treatment were elastic and almost like normal skin. The treatment had been scraping with the application of caustic potash in sticks.—Dr Permewan related a case of Acute Rhinitis which had caused general infection of the system and in which treatment of the nasal condition caused rapid subsidence of the fever.—Dr Carter said that in all cases of apparently inexplicable fever the nasal cavities should be carefully examined. He illustrated this general statement by brief reports of several cases.—Dr Clemmey in giving an account of a case of Rupture of the Kidney said that the patient received a kick from a horse on the front of the abdomen on Sept. 21st, 1898. The first symptoms of pain, collapse, retching, and hematuria were treated by fomentations and opium. On Sept. 30th, owing to the temperature rising and pain of a grinding character becoming more acute, the loin was opened exposing the ruptured kidney. The rupture extended half way through the substance, right across the posterior aspect, and into the pelvis of the kidney. Smart bleeding was controlled by ice and packing followed. On Dec. 6th the tube was removed and on April 13th, 1899, the wound was healed. The patient had since followed his employment as a "timber carrier." In three other cases of severe injury to the kidney with the ordinary symptoms of rupture no operation was required, rest, fomentations, ice, and opium being the treatment adopted. Whether secondary lesion of the kidney would follow in this case it was at present too short a time to say.—Dr Imlach, Dr Given, Mr Paul, and Mr Rushton Parker spoke on the case.—This being the last meeting the President briefly reviewed the proceedings of the session.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY—An ordinary meeting of this society was held in the society's rooms at the West London Hospital on May 5th, the President, Dr S. D. Clippingdale, being in the chair.—Dr Charles Chapman showed specimens of (1) Adherent Pericardium in a child and (2) Calcification of the Aortic Valves.—Mr H. J. Paterson read a paper on the Use of Gas in General and Dental Surgery. After explaining that his object was to plead for a more extended use of nitrous oxide anaesthesia he pointed out that although using the single word "gas" he implied thereby that it was given with a suitable proportion of air or oxygen. It had clearly been brought out by Dr Hewitt that gas should not be administered except in such combination. The advantages of gas were its safety, pleasantness, and freedom from causing after effects. He contended that it was safe, provided that asphyxial symptoms were avoided, to prolong nitrous oxide anaesthesia for one or more hours and recorded a case in which anaesthesia was maintained by means of gas and oxygen for two hours and 10 minutes. The patient was ready for his tea within half an hour of his return to the ward. There was no collapse whatever. Mr Paterson expressed the view that the action of nitrous oxide was to prevent the elimination of carbon dioxide from the blood, so diminishing the oxidative processes of the tissues by a process of "internal asphyxia." There was no evidence that prolonged administrations affected the heart and injuriously, provided that asphyxia was guarded against, and any effect on the heart was due to neglect of this precaution. In giving gas the danger, signs were readily observed and gradually developed, hence he had come to the conclusion clinically that for operations long or short nitrous oxide gas mixed with air or, better, with pure oxygen was the safest anaesthetic they possessed. Women as a rule took gas better than men. Heavy smokers, and especially the heavy drinkers, were bad subjects for this anaesthetic. The danger of passing from gas anaesthesia to chloroform was pointed out. Mr Paterson expressed the opinion that there were few operations which could not be performed under gas if desired and many in which this anaesthetic was preferable to either ether or chloroform. Manipulating joints,

A DAY OF REST IN THE COUNTRY FOR LONDON NURSES—For three years past the nurses of the London hospitals and metropolitan nursing institutions have been invited to spend a day at Hertfordbury. The object has been to combine with an opportunity of physical rest the spiritual help afforded by two short services held in the parish church. By the invitation of Canon Barnard this provision will be renewed on Thursday, June 1st when the Bishop of Southwark has kindly consented to give the address. The only expense to the nurses will be a railway fare of 2s 6d and those who can be spared from their work will be warmly welcomed. All information may be obtained from the Rev A G Locke chaplain of St. Georges Hospital, or from Canon Barnard, rector of Hertfordbury, Hertford.

Reviews and Notices of Books.

A Practical Handbook on the Muscular Anomalies of the Eye By HOWARD F. HANSELL, A.M., M.D., Clinical Professor of Ophthalmology, Jefferson Medical College, and WENDELL REBER, M.D., Instructor in Ophthalmology, Philadelphia Polytechnic and College for Graduates in Medicine With 28 Illustrations and one Plate London H. Kimpton 1899 Pp 182 Price 6s net

THE functional anomalies of the muscles of the eye have attracted of late years a large amount of attention in America and the subject is treated at great length in the treatises which have been published on the other side of the Atlantic. New terms have been suggested and have been accepted, and all ophthalmological treatises now consider orthophoria, esophoria and esotropia, exophoria and exotropia, hyperphoria and hypertropia, cyclophoria and heterophoria, conditions which were formerly very imperfectly described and understood. This present volume places before the reader in short compass the symptomatology, diagnosis, and treatment of each of these conditions and of the more complex states caused by their combinations—such as hyperexophoria and hypoxophoria, hyperesophoria and hypoesophoria. The volume commences with a brief but exact description of the anatomical features of each of the muscles moving the eye, as well as of the levator palpebræ and orbicularis palpebrarum, with their vascular and nervous supply and their precise action. The authors point out that the main symptoms by which ocular palsies reveal themselves are limitation of movement, false fixation, diplopia, vertigo, and, lastly, vicarious rotation of the head. The effects of paralysis of each of the muscles are given in detail. The means of diagnosis are well given and consist of the prism test, the Maddox rod test, the convex spherical glass test, the parallax test, the cover test, the cobalt test, and the Maddox double prism test.

There is a good chapter on Musculo-dynamics, describing the various instruments which have been devised to determine the power of the muscles to overcome the displacement caused by prisms put in different positions—such as Risley and Jackson's rotary prisms, Stevens's and Wilson's photometers, Stevens's tropometer and clinometer, and Landolt's ophthalmodynamometer. In regard to treatment, the authors contend that it should invariably be inaugurated by correction of any optical defect which may be present, then should follow in succession the internal administration of nerve tonics, convergence training, correction by prisms, and finally, tenotomy. A short section is devoted to this pulse and another to the operation for advancement of the tendons. The book will prove serviceable and should be read attentively by all who are practising the several operations.

By BARTON COOKE HIRST, M.D.
Ophthalmology. London: The Reban Publishing Co. 8vo Pp 850 1899 Price 28s

A Text-book of Ophthalmology By BARTON COOKE HIRST to the With 653 Illustrations. London: The Reban Publishing Co. 8vo Pp 850 1899 Price 28s

THE valuable contributions of Professor Hirst to the American Text-book of Ophthalmology lead us to anticipate with considerable pleasure the reading of a text-book of midwifery written by him. The book will prove serviceable and should be read attentively by all who are practising the several operations.

position or of intermittent uterine contractions as an aid to diagnosis. The author says that in extreme distension of the uterus it may be justifiable to resort to an exploratory abdominal section. Surely in such a case the passage of a uterine sound would at once clear up the diagnosis with much less risk to the patient. The chapters upon the Diseases of the Fœtus and the Pathology of the Pregnant Woman are perhaps the best in the book. We notice, however, one curious omission no mention is made of carcinoma of the cervix complicating pregnancy and nothing is said as to the treatment for such a condition. In considering the treatment of an ovarian cyst in the pelvis complicating labour Cesarean section is recommended, together with removal of the tumour. A better mode of treatment which is not alluded to is ovariectomy followed by delivery of the child *per vias naturales* the cervix, if necessary, having been dilated with hydrostatic dilators. The section upon Ectopic Gestation is illustrated by an interesting series of photographs from cases of sudden death due to this condition.

The chapter upon the Puerperium is full and contains a large amount of practical information for both students and practitioners. The description of obstetrical operations is, upon the whole, disappointing, and we must protest against the use of the term "postural version." The correction of a faulty position of the presenting part by placing the patient upon one or the other side cannot under any circumstances be called "version" and such a use of the term is most misleading. Professor Hirst is in favour of Krause's method of inducing labour and regards the use of dilatable bags with disfavour. So do we, but Champetier de Ribes's bag, which is not mentioned at all, is not dilatable and is certainly a most efficient and rapid method of causing dilatation of the cervix. This bag only bursts when it is improperly made or improperly used. We do not agree, either, with the author in thinking coelio-hysterectomy preferable to coelio hysterotomy. If the patient is very anxious to avoid the risk of another pregnancy this can be practically ensured by ligature and division of the Fallopian tubes without any necessity for the mutilation entailed by removal of the uterus.

Many of the illustrations are original and of great excellence, others, reproductions of photographs, possess all the faults of this mode of illustration. They present a mass of unnecessary detail which prevents the essential features of the illustration from being readily recognised and renders them less useful than drawings and diagrams would be to the student. We must protest, too, against the totally unnecessary reproduction of nude figures at various terms of pregnancy which show nothing of any value and might well be omitted.

Although we have expressed our disagreement with some of the views put forward by the author, and have had to call attention to one or two minor omissions, yet we must congratulate Professor Hirst upon the production of an original and eminently readable text-book, and one which is likely to be appreciated by students not only in America, but also in this country.

The Diseases of Children By JAMES FREDERICK GOODHART, M.D. Aberd., F.R.C.P. Lond., Consulting Physician to the Evelina Hospital for Sick Children, late Physician to Guy's Hospital and Lecturer in Pathology in its Medical School. Sixth edition with the assistance of G. F. STILL, M.A., M.D., M.R.O.P. Lond., Medical Registrar and Pathologist to the Hospital for Sick Children, Great Ormond Street, London J and A Churchill 1899 Pp. 720 Price 10s 6d

DR GOODHART'S book on the Diseases of Children is too well known to need any remarks from us on its general merits. In the preparation of the present edition Dr Goodhart has

Operations on the Lids with Transplantation of the Mucous Membrane of the Eye for the cure of Trichiasis in Trachoma. The subject of the Relation between the Intraocular Pressure in Accommodation and upon the Range of Accommodation in different Mammals was taken up by Dr O Hess of Marburg, but the results obtained owing to difficulties in experimentation do not seem to be very satisfactory. Dr A von Hippel, Dr W Uhthoff of Breslau, and Dr E Pädger of Berne gave details of two cases of Total Colour blindness. Dr H Sattler of Leipsic described an improved method of procedure which he had devised for the removal of the Lens in cases of Advanced Myopia. Dr L Laqueur of Strasburg in Alsace described a case of Homonymous Hemianopsia with the conditions found at the necropsy. Dr W Schoen gave an account of his researches on the Pathological Anatomy of Glaucoma Prolapsum Anatomicum. Dr F Dimmer of Innsbruck gave the results of his examination of the Chiasma and remainder of the Optic Tracts taken from a man from whom one eye had just previously been removed, although the vision was normal, for an epithelioma. The Formation of Thrombi was discussed in a paper by Dr J von Michel of Würzburg. Nævi and Sarcomata of the Conjunctiva were considered in a paper by Dr Hugo Wintersteiner of Vienna. Dr K Baas of Freiburg in Bavaria described the characters of Phlyctenulæ which he believed to be the response of diseased scrofulous tissues to many external stimuli. Dr G Abelsdorff of Berlin gave the appearances of the fundus of the eye in Malays, Mongols, and Negroes. Lastly, Dr A Greenow of Breslau read a paper entitled "Bacteriological Researches on the Etiology of the Inflammation of the Eye in Infants." A sitting of the congress was devoted to the exhibition of cases and the demonstration of preparations and instruments.

New Inventions.

NEW UTERINE PREHENSILE AND COMPRESSION FORCEPS

THE instrument depicted in the accompanying illustration will be found useful as a hæmostatic forceps not only in cases of passive hæmorrhage from the unimpregnated uterus, metrorrhagia, &c, but also in cases of free hæmorrhage in impending abortion in the early months of pregnancy. A duckbill or cylindrical speculum is first to be introduced and the parts are to be cleansed by hot water (syringing or otherwise). My self retaining tenaculum hooked into the lip of the os uteri will draw the cervix within the grasp of the forceps, the latter is now to be closed sufficiently to arrest the flow of blood, locked, and

left *in situ* so long as required while the patient lies quietly on the bed or couch. In cases of impending abortion in the early months by retaining the blood in utero it will distend the cavity, separate the membranes, and hasten the evacuation of the uterus when the forceps is withdrawn. It will also obviate the necessity for plugging the vagina. This forceps will be found valuable during the operations of supra vaginal amputation of the cervix uteri and vaginal hysterectomy. The convex shape of the blades will also prove a guide to the preliminary incisions in the vaginal roof when the cervix or the entire uterus is being removed from below, and by opening the blades to their full extent and pressing them upwards they will stretch the vaginal fornices and facilitate the removal of the cervix in the operation of abdominal hysterectomy. The instrument has been made by Messrs Arnold and Sons, West Smithfield, from my sketch and

description. The rubber cord let into the concave sides of the jaws prevents injury to the cervix from continued pressure. The blades are detachable and easily sterilised by placing in boiling water.

Cheltenham

ALEXANDER DUKE, F.R.C.P. Irel

APPARATUS FOR THE ADMINISTRATION OF OXYGEN

THE instrument represented in the illustrations is intended for the administration of oxygen gas and has been made by Messrs Krohne and Sesemann, Duke-street, W., on the lines of one previously used by me with satisfactory results. From a T piece secured by a head band there run

FIG 1

Profile view of head band forehead-piece supply pipe, and nasal and oral delivery tubes in adjustable carrier with nasal bridge.

FIG 2

Anterior view of head band, frontal junction-piece, supply pipe, and nasal and oral delivery tubes in adjustable carrier settled in position by nasal bridge.

four rubber tubes mounted on flexible wire in order to enable them to retain their position. These tubes are, moreover, kept in place by a carrier settled by a nasal bridge,

passing through the above-mentioned slits are fastened to ordinary dress hooks on the corset. By an ingenious arrangement of hooks in front the belt is prevented from rising up out of its proper place and at the same time the use of uncomfortable understraps is altogether avoided. The belt is very light, weighing only three ounces. The price is £2 2s in silk, or £1 1s in white cord. Cheaper qualities are made in grey jean for hospitals and dispensaries.

THE METROPOLITAN HOSPITAL SUNDAY FUND

A MEETING of the Council of this Fund was held in the Mansion House on Wednesday, May 10th, when Sir Sydney Waterlow presided. Among those present were Sir E. Hay, Glover, Sir George Bruce, Rev. C. H. Grundy, Mr. A. L. Cohen, the Rev. Frederick Kitchin, the Right Hon. William Liddell, and Mr. Albert G. Sandeman. Among the letters of regret for inability to attend the meeting was one from Mr. Augustus Thorne who enclosed a donation of 100 guineas. The Rev. J. Bradford, the Rev. Canon Pennington, the Rev. G. R. Thompson, and Dr. Stephen Mackenzie were elected to fill vacancies on the Council. The question of more largely advertising the next annual collection was referred to the General Purposes Committee, as was also a letter from the Rev. G. R. Thompson suggesting that the clergy of all denominations should be summoned once or twice a year to hear a popular lecture in order that they might be able to appeal more forcibly to their congregations. For the same purpose the Rev. O. H. Grundy suggested that a reception of clergymen should be held at the Mansion House, when they could discuss among themselves the best means of making collections and of appealing to their congregations. Mr. A. L. Cohen did not see the use of such a meeting and said that valuable help was given to clergymen already by the annual Supplement of THE LANCET. The question of the date of the 1901 collection clashing with the bicentenary of the Society for the Propagation of the Gospel was brought before the meeting and this matter was also referred to the General Purposes Committee. A vote of thanks to the Chairman, proposed by Dr. Glover who complimented Sir Sydney Waterlow upon the vigour and energy which recovered health had enabled him to display brought the meeting to a close.

HEALTH OF LANCERS—TYDYL—The medical officer of health (Mr. Dyke) reports that during 1898 there were 2495 births registered giving a rate of 34.7, of these 73 equivalent to a rate of 2.92 were illegitimate. Vaccinations were performed in 1870 instances by public vaccinators. There were 1409 deaths, compared with 1598 in 1897, equal to a rate of 19.5 per 1000. The present population is 71,903 with 12,912 occupied houses recorded in this district.

BATTLE OF THE CLUBS THE GOVERNMENT PUBLIC MEDICAL SERVICE

—The annual meeting of the service was held last week. There were present Mr. Rauder White (in the chair), Dr. Brown, Mr. Callaghan, Mr. Collington, Mr. Phillips, Dr. Rice, Mr. Soden, and Mr. Settle. The treasurer reported that the financial condition of the service was highly satisfactory. The general working also appears to proceed smoothly and no complaints have reached the secretary during the year. It would thus appear that a medical service of this nature can be worked on practical lines and give satisfaction to the medical staff who have organised its working. The committee also take every precaution so that the benefits are reserved exclusively for genuine working people. It was reported that 2800 members were enrolled during the year bringing the total membership to 8281. There are 10 working members of the staff and as the number under each is strictly limited the committee feel that there is no great danger of overcrowding or lack of attention to individual patients. The following officers were elected for the ensuing year: President of Committee, Dr. Hais, honorary treasurer, Mr. Callaghan, honorary secretary, Dr. Richardson Hice.

which can be adjusted to a long or short nose by the screws and arms at the extremities of the horizontal limb of the T piece. The four tubes wire-mounted and curved, end in vulcanite nipples. The nasal tubes do not pass into the nostrils but are merely inserted at the most anterior part of each nasal aperture, permitting free inspiration and expiration. The mouth tubes run to the angles or to just within the angles of the mouth. After a fair trial of face-pieces, nose and mouth tubes, and funnels, I have adopted the above, which I venture to hope may also be of service to others requiring an oxygen inhaler. My object has been to avoid as far as possible the cause of suffocation imparted by an ordinary face piece, also the discomfort of a tube passed into the nostril or a mouth piece which enters conscious tobacco smokers' nostrils in treating as a pipe-stem. Evidently there is free means of escape for the respiratory wastes products. A pneumonia patient breathes either solely through his nose or through his mouth, and when this occurs the tubes which he does not make respiratory use of can be closed by pinch clips or taps provided for the purpose. The oxygen can be kept in a gas-bag under the bed delivering continuously so many cubic feet per hour and is supplied by a tube bending over the head of the bed. The absence of a face-piece or funnel tends to prevent the patient's friends entertaining ideas of an "anaesthetic" which might be the cause of the unsatisfactory termination of a severe case. F. W. FORBES ROSS, M.D. Edin., D.P.H. Governor-street, W.C.

A NEW COMBINED PATHOLOGICAL AND BACTERIOLOGICAL POST-MORTEM CASE

I would direct attention to a combined pathological and bacteriological post-mortem case which has been made for me by Messrs Arnold and Sons of London. The instruments which are contained in it are of the "aseptic" type while the metal aseptic body contained in its wooden covering can when removed from the latter be used as a tray to hold antiseptics. In such a case it has been a

A NEW CORSET BELT

Alexander Edington, M.B. Edin. Bacteriological Institute, Gresham-street.

We have received from Mrs. W. G. Johnson of 7, Old Bond street, W., a sample of Howell's patent self-adjusting corset belt, a well made and serviceable article which has been found to give useful support not only in cases of obesity but also during pregnancy and after abdominal operations. It does not go quite round the body but is worn under a corset which is prepared for it by having two button holes made over the hips on each side. Each end of the belt has two straps with a row of elastic holes and these straps

THE LANCET.

LONDON SATURDAY, MAY 13, 1899

ON March 22nd, 1800, the Royal College of Surgeons of England received its first Charter and the Council of the College has decided to celebrate in 1900 the hundredth anniversary of this important event. The history of the way in which this Charter was obtained is instructive, for it affords a clue to much that otherwise would be difficult of comprehension in the annals of the College. In 1797 a Bill was introduced into the House of Commons to re-establish the old Company of Surgeons which had been practically destroyed by the illegal action of the Master and the Court of Assistants. Although this Bill had passed through the House of Commons and the second reading in the House of Lords, yet it was ultimately rejected chiefly as a result of a petition from the members of the old Company of Surgeons who showed that the Bill would put an end to many of the privileges which they had previously enjoyed. But three years later (the Court of Assistants having in the meantime accepted the charge of Hunter's Museum) a Charter was obtained directly from GEORGE III without the intervention of Parliament. By this Charter the Members of the College were utterly excluded from all participation in the government of the College, general meetings of the corporation were no longer to be held and the whole management of a body with great powers and greater privileges was vested in a self electing Council. The Charter of 1843, by the creation of the order of Fellows, did something to give a representative character to the government of the College, but the large majority of the constituents of the College remained as before shut out from any share in the election of the members of the Council from examinerships and other posts of emolument or honour. Even to the present day, though slight modifications in the Charter have been made, the Members as such are still as far as ever from having the position which is their due in the management of the affairs of the corporation.

Though we have on so many occasions urged the claims of the Members of the College, so often pointed out, almost from the first appearance of THE LANCET, the errors, the anachronisms, the wilful blunders of the Council of the College, we have not been unmindful of the many advantages which have accrued to the science and practice of surgery from the establishment of this institution, and we have ever been ready to acknowledge the good which it has done, for with all its faults—and they are many—the Royal College of Surgeons of England is the greatest and chief representative of English surgery. The good which it has done has been very great but the good which it might do is still greater.

Appreciating, then, as we do the benefits which the Royal College of Surgeons of England has conferred on surgery in

this country, we welcome the suggestion that the centenary of the granting of its first Charter should be worthily celebrated. At the last meeting of the Council the recommendations of the committee appointed to consider the matter were adopted. In addition to dinners and other similar festivities it is intended that a supplementary Charter shall be applied for which will enable the Council to confer an Honorary Fellowship on distinguished persons, British and foreign, who are *not* Members of the College. With this suggestion we heartily agree, for there is no way in which the appreciation of the College can be shown more appropriately than by the conferring of an honorary diploma. This power is possessed by all the older Universities of Great Britain, and indeed by most of the universities in the world, and if employed judiciously it serves a most useful and valuable purpose. Many of the members of the Council have themselves been the recipients of such an honour from universities and colleges both of this country and abroad. It is very desirable that a body like the Royal College of Surgeons of England should possess the power of showing its appreciation of the merit of distinguished men who have done service to surgery or to other branches of science. There need be no fear that these honorary diplomas will be mistaken for the diploma of Fellow obtained after examination or by election from among existing Members. Such an error practically never arises, for the honorary diploma will of itself give no claim to the recipient to be placed on the Medical Register.

It will have been noticed that these honorary degrees are not to be granted to those who are already Members of the College, for the Council already under the present Charter possesses power to grant the diploma of Fellow to Members of 20 years' standing, although the number of diplomas which may be thus conferred is limited to two every year and might well be increased. To obtain these new and important powers it is necessary, as already mentioned, to apply for a new Charter, and the cost, though by no means small, need not be seriously considered, but while a new Charter is being applied for, would it not be well to insert in it some of the modifications which have been so persistently and so reasonably asked for by the Members of the College? No one, we should imagine, either Fellow or Member, will in any way oppose the application which the Council intend to make, for the new powers will be universally recognised as eminently desirable. Can any time more suitable than the present be chosen for the application for a new Charter in which the hitherto discordant elements of the College shall be united into one consistent whole? The claims of the Members have been recognised by meetings of the Fellows, many members of the Council itself are in favour of some concession and the reasonableness of the Members' requests has never been seriously impugned. We appeal, then, to the Council of the Royal College of Surgeons of England to consider carefully whether they cannot insert in their proposed new Charter clauses which will give to the large body of Members of the College at least some share in its government. A hundred years ago the privileges of the Members were arbitrarily taken away, the closing year of the eighteenth

We speak thus after seriously considering the significance of the meeting on Monday last Sir WILLIAM BROADBENT

Much was said at the meeting about the funds—the

THE LANCET.

LONDON SATURDAY, MAY 13, 1899

ON March 22nd, 1800, the Royal College of Surgeons of England received its first Charter and the Council of the College has decided to celebrate in 1900 the hundredth anniversary of this important event. The history of the way in which this Charter was obtained is instructive, for it affords a clue to much that otherwise would be difficult of comprehension in the annals of the College. In 1797 a Bill was introduced into the House of Commons to re-establish the old Company of Surgeons which had been practically destroyed by the illegal action of the Master and the Court of Assistants. Although this Bill had passed through the House of Commons and the second reading in the House of Lords, yet it was ultimately rejected chiefly as a result of a petition from the members of the old Company of Surgeons who showed that the Bill would put an end to many of the privileges which they had previously enjoyed. But three years later (the Court of Assistants having in the meantime accepted the charge of Hunter's Museum) a Charter was obtained directly from GEORGE III without the intervention of Parliament. By this Charter the Members of the College were utterly excluded from all participation in the government of the College, general meetings of the corporation were no longer to be held and the whole management of a body with great powers and greater privileges was vested in a self electing Council. The Charter of 1843, by the creation of the order of Fellows, did something to give a representative character to the government of the College, but the large majority of the constituents of the College remained as before shut out from any share in the election of the members of the Council from examinerships and other posts of emolument or honour. Even to the present day, though slight modifications in the Charter have been made, the Members as such are still as far as over from having the position which is their due in the management of the affairs of the corporation.

Though we have on so many occasions urged the claims of the Members of the College, so often pointed out, almost from the first appearance of *THE LANCET*, the errors, the anachronisms, the wilful blunders of the Council of the College, we have not been unmindful of the many advantages which have accrued to the science and practice of surgery from the establishment of this institution, and we have ever been ready to acknowledge the good which it has done, for with all its faults—and they are many—the Royal College of Surgeons of England is the greatest and chief representative of English surgery. The good which it has done has been very great but the good which it might do is still greater.

Appreciating, then, as we do the benefits which the Royal College of Surgeons of England has conferred on surgery in

this country, we welcome the suggestion that the centenary of the granting of its first Charter should be worthily celebrated. At the last meeting of the Council the recommendations of the committee appointed to consider the matter were adopted. In addition to dinners and other similar festivities it is intended that a supplementary Charter shall be applied for which will enable the Council to confer an Honorary Fellowship on distinguished persons, British and foreign, who are *not* Members of the College. With this suggestion we heartily agree, for there is no way in which the appreciation of the College can be shown more appropriately than by the conferring of an honorary diploma. This power is possessed by all the older Universities of Great Britain, and indeed by most of the universities in the world, and if employed judiciously it serves a most useful and valuable purpose. Many of the members of the Council have themselves been the recipients of such an honour from universities and colleges both of this country and abroad. It is very desirable that a body like the Royal College of Surgeons of England should possess the power of showing its appreciation of the merit of distinguished men who have done service to surgery or to other branches of science. There need be no fear that these honorary diplomas will be mistaken for the diploma of Fellow obtained after examination or by election from among existing Members. Such an error practically never arises, for the honorary diploma will of itself give no claim to the recipient to be placed on the Medical Register.

It will have been noticed that these honorary degrees are not to be granted to those who are already Members of the College, for the Council already under the present Charter possesses power to grant the diploma of Fellow to Members of 20 years' standing, although the number of diplomas which may be thus conferred is limited to two every year and might well be increased. To obtain these new and important powers it is necessary, as already mentioned, to apply for a new Charter, and the cost, though by no means small, need not be seriously considered, but while a new Charter is being applied for, would it not be well to insert in it some of the modifications which have been so persistently and so reasonably asked for by the Members of the College? No one, we should imagine, either Fellow or Member, will in any way oppose the application which the Council intend to make, for the new powers will be universally recognised as eminently desirable. Can any time more suitable than the present be chosen for the application for a new Charter in which the hitherto discordant elements of the College shall be united into one consistent whole? The claims of the Members have been recognised by meetings of the Fellows, many members of the Council itself are in favour of some concession and the reasonableness of the Members' requests has never been seriously impugned. We appeal, then, to the Council of the Royal College of Surgeons of England to consider carefully whether they cannot insert in their proposed new Charter clauses which will give to the large body of Members of the College at least some share in its government. A hundred years ago the privileges of the Members were arbitrarily taken away, the closing year of the eighteenth

the Registrar of the General Medical Council that the man registered as EDWARD JOSEPH NUGENT was an impersonator but that nothing was done to revoke the registration or prevent further deception of the public until a magistral calamity had its outcome in penal servitude for the criminal. Several things were then said as to the supervision of the Council, but the critics were, to our thinking, not quite mindful of the difficulties of the Registrar's work. A man named EDWARD JOSEPH NUGENT had a right to a place on the Register until he died or did something which under the proper provisions of the Medical Act would enable the Council to remove his name. But we will admit that we are a little surprised to find the following entry in the new Medical Register, published only a fortnight ago—

Name, Edward Joseph Nugent, address, 38, Barkings-road, Canning Town, London, E, date and place of registration, 1868, Sept. 15th, Ireland, qualifications, Lic. R. Coll. Surg. Irel., 1866, Lic. R. Q. Coll. Phys. Irel., 1872.

It is known, and has been known for several months, that the man who practised in the neighbourhood of Canning Town, and whose present address is one of Her Majesty's prisons, was not NUGENT but BOWLAND, and also that NUGENT's address is somewhere in Australia. Taking these considerations with the sworn allegation that the real Nugent on the eve of his departure from England handed over his diploma to his impersonator in consideration of £60 a week to be allowed to the wife whom he was deserting, we think a strong case is made out for the temporary exclusion of the entry from the Register pending any further proceedings deemed necessary, and we should like to hear the official reason for having acted otherwise.

Annotations.

No quid niter.

THE LAW AS TO CONSTRUCTIVE MURDER

MR. PITT-LEWIS, Q. C., has contributed to the *Times* an article under the above heading in which he reviews the difficulties and discrepancies which have recently arisen in cases where death has followed by induction the nature of the measure which in his view would best put a stop to them. That the discrepancies exist no one will deny and the fact that the law as it stands does not command itself to judges owing to its severity is not an unprecedented circumstance. The same state of affairs arose when the capital sentence was pronounced for comparatively trifling crimes the jury acquitted guilty prisoners, or where they convicted communists followed as a matter of course until an Act of Parliament more in accordance with the spirit of the age was passed. The Act now needed, according to the view of Mr. Pitt-Lewis, should first "declare the law to be as it was laid down by Sir L. Foster by the late Mr. Justice Blackburn, and by the late Chief Justice Cockburn and Baron Bramwell, and as the great majority of lawyers still believe it to be", that is, presumably that "if a man in committing or attempting to commit a felony kills another he is guilty of murder. A second section, he continues, should follow this one and enact that, in cases coming within the first section of the Act the

THE ELECTED AMERICAN FELLOW OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE admission by election of an American surgeon to the Fellowship of the Royal College of Surgeons of England at any time would be an interesting event. It is especially so at the present period when in the evolution of history a new recognition is being given everywhere to the essential alliance between England and the United States. In no sphere is this more important or more seemingly than in the serene atmosphere of science, and in no branch of science more than in that of medicine. The professors of this branch on both sides of the Atlantic have long stood with each other in every demonstration of friendship and hospitality. We offer our congratulations to Frederick Shepard Dennis M.D., Professor of the Principles and Practice of Surgery in the Bellevue Hospital Medical College, A.C., to whom the unprecedented honour, as an American Member of the College of 20 years' standing, of election to the Fellowship has fallen. The election is not more honourable to Professor Dennis than it is creditable to the College. Few men combine the qualities and the merits

some of its passages

generally is by no means easy to follow or to agree with in numerous writer, and his article, though interesting and suggestive, Mr. Pitt-Lewis, however, is a learned rather than a templed that it would result in death," a very different slaughter "if he could not as a reasonable man have consulting Whitmarsh said that his act could only be maintained in one place to suggest, for that learned judge in the opinion of Mr. Justice Biglam, as Mr. Pitt-Lewis seems verdict of manslaughter." This is not in accordance with veridically performed it was open to the jury to return a not done was not such as of necessity to cause danger if not which most other lawyers have not assented, that "if the law laid down by the Attorney General in the Collins case, to was no doubt suggested by the interpretation of the existing laws rather than to deal with the question generally. It designed chiefly to meet cases of death through illegal operation a competent witness, while it seems to have been conceivably given, except perhaps by the prisoner, who is exceedingly difficult one to base on any evidence which could the special finding suggested by Mr. Pitt-Lewis would be an consummation which few would desire. On the other hand a stranger behind him would allow escape hanging, a shooting at a man to murder him missed him but killed train causing many deaths in so doing and the man who law the man who with robbery as his object "received a felony", and it has been suggested that if this were the of the commission of or attempt to commit some other that he caused the death of the deceased by or in the course shall be imputed to the accused merely because it is shown upon a trial for murder no constructive or implied malice be remembered, would meet the difficulty by enacting "that Mr. Ambrose, Q. C., and Sir Andrew Scoble. This, it will or us better than the Bill introduced into Parliament by that it appears to aim at interpreting the wishes of most in his own discretion. It must be said in favour of the assigns such sentence of death to a term of penal servitude of passing it in open court and to mitigate during the would be empowered to record the sentence of death instead its so resulting. The judge upon such special findings reasonable skill, and all other means in his power to prevent death would not result from such act, and that be used all reasonable ground for believing, and did, in fact, believe, that the act which led to the death of the deceased had leading to the effect that the accused, when the jury trying the case might appeal to their verdict a special

Hospital Sunday Fund, the Hospital Saturday Fund and the Prince of Wales's Fund, taking them in the order of their seniority. Opinion is not unanimous as to the wisdom of preserving the individuality of all these Funds and as to the value of the principles upon which they are distributed. It would be calamitous if, as Lord METHUEN, the chairman of the meeting, seemed to think, the Funds were "treading on each other's toes." The two older Funds appeal in a convenient way to classes which clearly need to be appealed to annually in such a way. The Prince of Wales's Fund is essentially a Jubilee fund and may with splendid effect be yet carried to its consummation within some definite period in connexion with the incomparable reign which it commemorates. His Royal Highness the PRINCE OF WALES we are sure will rightly use his own sound judgment on this question. What we are most concerned about now is to see the harmony of the profession restored on the question of hospital abuse and its natural leaders guiding the lay authorities of hospitals into sounder principles of hospital administration.

THE Medical Register is the most important manifestation of the work of the Medical Act of 1858. That Act, as we know, was passed in recognition of the obvious expediency "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners," and to render such discrimination practically unfailing it provided for the maintenance of an official roll. On the roll—the Medical Register, that is—were to appear the names of all duly qualified practitioners, so that if the public were in doubt about the status of any individual claiming to be a qualified medical man consultation of the roll would settle the matter at once. It is clearly, therefore, essential to the purposes of the Medical Act of 1858, the Act by which our profession is ordered and under which the General Medical Council was created and does its work, that the Medical Register should be accurate, and should include the names of all duly qualified practitioners, their addresses, and the dates on which they obtained their qualifications—and no other names. There is no part of the work of the General Medical Council in our opinion better worth doing, thoroughly than the work which is directed towards maintaining the Register at a high level of accuracy.

We may say at once that we regret our inability to consider the Medical Register for 1899 an accurate book of reference, though we have no reason to suppose that it is in any respect an inferior compilation to previous Registers. We said last week that in as many minutes we were able to find the names of 21 dead persons on the Medical Register. The importance of this fact lies in the wide door which is thus opened to the impersonator. 16 of these deceased members of our profession resided in the colonies, and as long as their names appear on the Register it seems to us that any persons almost with impunity can practise in England on their credentials—for which reason we do not quote the entries in question though our information is at the service of the General Medical Council. It may be asked—How is the Registrar to obtain information of a practitioner's death? The deceased man cannot notify the sad occurrence himself and

his relations probably never think it necessary to do so. And for these very reasons it is our belief that the names of many more dead persons than we have been able to detect in a quick survey of the book are still printed in its pages. But the names of the 16 deceased colonial practitioners to which we have referred happen to be in the obituary of the Australasian Medical Directory for 1896, the dates of death ranging between the years 1892 and 1898, so that the information would not have been hard to come by. We do not mean that the Registrar should accept as official the obituary list of the Australasian Medical Directory. But Section XIV of the Medical Act of 1858 indicates the discretion that is allowed him in such matters. Has the procedure under the Act been adopted? If so, either these gentlemen have replied to the Registrar, in which case the obituary list of the Australasian Medical Directory is fine imaginative literature, or they have not replied, in which case why do their names persist?

In the matters of addresses and qualifications the Medical Register of 1899, like its predecessors, is incorrect and incomplete. Here the fault is clearly in the first instance on the side of the practitioners who do not keep the Registrar adequately informed on these points. The Registrar prints yearly "Important Notices" at the beginning of the Register urging on practitioners the duty of giving immediate notice to the Branch Registrar by whom they were registered of any changes in their addresses, and the advisability of registering their full qualifications. But his words go unheeded. This being so we think that the Council are to blame now for their leniency towards the indifference of the profession. For many years medical men agitated for an authoritative or official list that the public might find on it the correct names and styles of all persons duly instructed in the healing arts, and might no longer have an excuse for recourse to quacks, yet now that the machinery exists for the compilation and publication of the list many medical men take no steps to have their names correctly entered upon it. We recommend the penalisation of the indifferent. A systematic comparison of the Medical Register with CHURCHILL'S excellent Directory would indicate a large proportion of the offenders, so that we are not suggesting any such extravagant proposal as the immediate issue of 30,000 registered letters. The persons whose addresses and descriptions are believed to be incorrect could all be written to in the course of the next three months and the information gained from their replies would in our opinion considerably enhance the value of the Register.

To one other matter we wish to refer. The startling revelations made at the trial of JULIAN ROWLAND¹ for the manslaughter of a woman named JANE ELIZABETH SMITH by his terrible neglect of her when in labour aroused feelings of uneasiness in the public as well as among the profession because of the impunity with which the man ROWLAND, an unqualified person, had been able to practise as a medical man under the name and style of EDWARD JOSEPH NUGENT, a Licentiate of the Royal College of Physicians of Ireland resident in Australia. It was stated in evidence at the trial that information had been given

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND
Such assistance would be invaluable on the West Coast of Africa, for instance, where trained nurses have to be a European nurse in charge, but trained native women would find a wide field of usefulness

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

OWING to the fact that the President of the Royal College of Surgeons of England is elected annually on the second Thursday in July, while the members of Council are elected on the first Thursday, it is theoretically possible that the President might cease to be a member of the Council one week before he would cease to be President. To obviate this difficulty Section 2 of the Charter of the 15th Victoria enacts that the President under such circumstances shall remain a member of the Council for one year longer without re-election. This year the term of office of the President (Sir William MacCormac, Bart., K.C.V.O.) as a member of Council comes to an end before his term of office as President and his membership of the Council will consequently be prolonged until July, 1900. It is interesting to recall the only other occasions on which this rule has come into operation. They are three in number—viz., (1) Mr. Thomas Wormald, President, 1865-66, did not retire from the Council till 1867, (2) Mr. Richard Partridge, President, 1866-67, did not retire till 1871. Each of the above gentlemen would have retired a year earlier in the course of ordinary rotation

CHILD LABOUR AND ITS HYGIENIC ASPECTS

THE problem of child labour in its hygienic aspects, to which attention was called in our columns a short time ago, has now entered upon a more public and perhaps more important phase. It was referred to and dealt with in some detail by Sir John Gorst, the Vice-President of the Council of Education, when submitting the Education Estimates, in his speech on April 28th last, and must invite the serious consideration of authorities on education and legislators as well as of the public generally. Since attention was first drawn by Sir John Gorst to this subject in Parliament last year returns had been received from nearly all the 20,000 board schools of England and Wales in reply to inquiries issued from the Education Department. "They were painful and sickening returns," said the speaker, "casting a lurid light upon the social conditions of large classes of the population and proposing a difficult and complicated problem for Government and the school boards as full time scholars. 110,000 boys and 34,000 girls were engaged as labourers out of school hours for wages and profit. The great bulk of these were, as the returns showed, children of tender years and beyond their powers. Thus 6268 children were employed from 10 to 20 hours a week, 27,000 from 20 to 30 hours, 9778 from 30 to 40 hours, 2350 from 40 to 50 hours, and 730 worked over 50 hours a week. One little boy worked 47½ hours a week as an undertaker's assistant at the gruesome task of measuring corpses and received 1s a week for his labour. A boy, aged six years, worked for 20 hours a week peeling onions at a weekly wage of 8d., another delivered milk for 28 hours a week and received 2s. A girl under six years of age worked 35 hours a week as a mill-carrier for her parents, and another girl under six years of age worked 16 hours a week for 1d. A nurse-girl (sic) under six years of age was employed 29 hours a week for 2d and her food. Others were employed in laundry work, basket-making, minding babies, &c. The

occupations for boys consisted of agricultural labour, in which 6115 were employed, selling newspapers in the streets, in carrying dinners and rousings workmen early in the morning, which gave occupation to 19,263, while 76,173 were engaged in working in shops. Some examples given by Sir John Gorst speak for themselves. A boy, aged 10 years, worked as a farm labourer 72 hours a week for a wage of 3s., a boy, aged 12 years, was engaged in a druggist's shop in London 78 hours a week for a wage of 5s., another little labourer, aged 12 years, worked 87 hours a week for half a crown, and a little girl worked 72 hours a week in a shop earning 2s a week. A boy, aged 12 years, was a greengrocer's assistant and had to start from London at 2.30 A.M. on his duties, returning home about 9.30 A.M., rose between 3 A.M. and 4 A.M. every morning and started on his rounds at 4.30 A.M. to taken 25 working men on his rounds at 5.30 A.M. but did not go to bed, as he went out from 6 A.M. to 9 A.M. selling or distributing newspapers. After this he attended school, where he was described as a very regular boy in his attendance but often half asleep and unfit for receiving intellectual instruction. The effects of this extra manual labour and these long hours have been pointed out already in our previous observations already alluded to. "Probably some die as a direct result of the severity of the toil inflicted upon them during their early years, and certainly many more of them must become a permanent and heavy charge upon the public purse because of the physical incapacity resulting from the neglect of their early experiences." These are the grave words embodied in a report concerning these children which was laid before the School Board on Feb 16th last. The inquiries made since have but served to amplify and confirm this Sir John Gorst described the sufferings of these overworked and underfed children in passages which were genuinely eloquent and profoundly touching. These little slaves were brought out one by one with every detail in their picture was one to haunt the memory for many a day after proposals of various kinds have been made to obviate or mitigate this evil. These boys and girls are destined to be the future parents of the community demands that they should be physically and mentally able and vigorous so that they may be the parents of healthy children. The suggestion that Parliament should prohibit child labour for children of school age. This, perhaps, is too drastic a proposal. It might well come within the scope of county councils to frame by laws preventing the labour of, say, children under 12 years before 8 A.M. and after 8 P.M. and to limit the total hours of labour per week to, say, not more than 20 hours. But public opinion also must be educated before legislation can be enacted and in this as in so many other respects an enlightened public opinion will be a most important factor for good.

A NEW DEPARTURE IN HOSPITAL APPEALS

THE Board of Management of the National Hospital for the Paralyzed and Epileptic, Queen's Square, Bloomsbury, have issued an appeal which, like the address in the Commission Service, is made up of a series of utterances from the lips of various eminent men who have time to time advocated the claims of the charity. They are blended into one harmonious whole and should certainly help to enlist the sympathies of the charitable. Another novel feature is a scheme to return to donors unable to sacrifice present income but desirous to benefit

of an elected Fellow more than he does. His personal devotion to surgery both as a teacher and a practitioner and the embodiment in him of all that completes our conception of a genial American gentleman point him out as worthy to receive the compliment paid to him by his College. It is to this genial quality of his nature that he owes not only his large circle of friends in Great Britain and other European countries, but the fact that he has been able to associate with himself as editor so many distinguished compatriots in the compilation of his splendid "System of Surgery" written throughout by American surgeons.

THE AFTER-CARE OF DISCHARGED PAUPER LUNATICS

No patients require more special aid and after care on leaving the institutions where they have had to remain under treatment and until recovery than the pauper insane. The After-care Association for poor persons discharged recovered from asylums for the insane is the only charity of its kind in the United Kingdom and during the few years of its existence its scope and sphere of work and usefulness have steadily increased. The annual report of the council of the association for the year ending Dec 31st, 1898, is a record of satisfactory progress. The work undertaken by the society can never be expected to become very popular in the strict sense of the word, nor can its progress be judged by comparing it with other charities as its difficulties are very much greater—viz., in affording help to those poor people who have recovered from insanity and whose chances of a livelihood in a struggling age are greatly diminished if not altogether lost. Thus, during the twelve months of 1898 there were 186 cases from different parts of the country before the council, as compared with 147 in the same period in 1897, and this is by far the largest number ever brought under the notice of the council in one year. Of these 131 were women and 55 were men. Convalescents have been assisted in such ways as past experience has shown to be best—viz., by being boarded out in cottages in the country, by finding occupation for them, or by grants of money, clothing, &c. Some have been placed in domestic service, a procedure which requires much care and knowledge for its successful carrying out, as all employers have to be interviewed and the cases for placing out very judiciously selected, especially in the case of young females. All are visited periodically by officers of the association and it speaks well for this branch of the association's labours that a very large majority of cases so placed out and helped to help themselves have retained their situations, while the failures during the year have been comparatively few. The boarding-out of suitable convalescents in cottage homes in the country has been continued with much success. These houses are mostly situated in the south of England and are inspected by the secretary before anyone is sent, and they are also visited from time to time by him at short intervals. Last year the council of the association decided to send particulars of the work of the association to various boards of guardians in England and Wales requesting information regarding all patients discharged as recovered from public asylums to workhouses, so that inquiry might be made into those cases likely to be benefited by the After-care Association and it is gratifying to note from the readiness of several boards to give such information that success in this direction seems probable. We note that among the unions which subscribe to the funds of the association are those of Olapham, Wandsworth, Fulham, and Paddington and that among the City Guilds, &c., which give donations towards it are the Worshipful Companies of Mercers, Fishmongers, Salters, Clothworkers, Skinners, Merchant Taylors, and Leathersellers. Cases have been assisted from among the discharged patients of all the London County Asylums and of the various public asylums of Middlesex, Essex, Kent, Sussex,

and other southern counties. The scope of the association, however, goes further north and convalescents from Nottingham, Lancashire, &c., have also been recipients of its bounties. A few concrete instances will serve to show the kind of work done for discharged paupers who have recovered from insanity. Case 598—A young orphan girl discharged recovered from an asylum boarded out and trained for domestic service and a suitable situation subsequently found for her. Case 589—A girl deserted by her parents for many years boarded out at the seaside after recovery from an attack of insanity and afterwards placed in a suitable situation. Case 20—A lad who had been in an asylum since the age of seven years boarded out for several weeks and placed in a suitable situation. Case 602—A man from a London asylum was assisted by the association to obtain rest and change and to recruit his mind and body and was afterwards taken back by his old employers. Owing to increase of work since January, 1899, the council has been obliged to appoint a second lady visitor at a salary of £40 per annum so that the visiting and placing of female convalescents may be efficiently carried out. The council earnestly appeals for additional help either in the way of personal service, funds, or otherwise. It is evident from the report that the work done—quiet and unobtrusive though it be—during the past year has been the most successful in its annals, but it needs the warm cooperation and assistance of officers and authorities of the various public and private asylums and boards of guardians of the poor throughout the country for its continued success. Surely no charitable body deserves better than the one which helps recovered lunatics to live so that they may not relapse and lose their reason again, but may continue "clothed and in their right mind." The offices of the association are at Church House, Dean's Yard, Westminster, S.W., and the address of the honorary secretary is Chaplain's House, Colney Hatch, N.

THE COLONIAL NURSING INSTITUTION

In a letter to the daily press Mrs Chamberlain asks permission to draw attention to the Colonial Nursing Association. It was to supply the known want of any provision for good nursing in the colonies, and especially those which lie within the tropics, that the Colonial Nursing Association was formed in 1896 with a small fund, raised by private subscription, and with the intention of encouraging and organising the supply of trained nurses in cases where the localities had been unable to secure this provision. The association carefully selects the nurses, pays their passage out, and guarantees their salary for a term of years. It arranges the conditions and terms of service and furnishes all information on the subject. Wherever possible the expenses are provided locally, and the residents in the colonies are expected to pay for themselves as soon as the initial difficulties have been surmounted. The movement has the cordial support of the authorities of the Colonial Office who have taken advantage of the organisation to provide nurses for Government institutions maintained in Hong Kong, Cyprus, Trinidad, Bahamas, the Gold Coast, Lagos, the Niger Protectorate, and other places, while the following colonies and settlements have been supplied through the agency of the association with nurses for private patients—viz., Mauritius, Perak, Selangor, East Griqualand, Cyprus, Ceylon, and Bangkok. Six other colonies have applied for aid and will be similarly supplied during the present year. Money is wanted, but a sum not exceeding £5000 would be sufficient, in the opinion of the committee, to meet all wants. Subscriptions will be received by the Honorary Treasurer, Colonial Nursing Association, Imperial Institute, London, W. We hope that the association will not confine itself to sending out European nurses but will also endeavour to train up a school of native

But in trichinosis this may be slight and not attract attention. In a severe case the swelling and hardness of the muscles, the extreme tenderness, and the position of flexion without redness or swelling of the joints are almost pathognomonic. Early in typhoid fever these are never seen. But later there may be swelling and tenderness of the muscles. Dr Osler has described such cases (Oedema which in its most characteristic form is seen in the eyelids and over the eyebrows is of great value because of its early appearance. It was characteristic in four cases in the hands and feet it is more commonly seen late in the disease (Oedema with slight erythema above the swollen tender muscles is very characteristic. Leucocytosis and eosinophilia are important features. It is only recently that Brown has found leucocytosis and great relative increase in the number of eosinophile cells. In all cases this question remains whether in other forms of infectious myositis the eosinophiles are greatly increased. But such cases are extremely rare and if eosinophilia does occur the diagnosis can be made by examining a portion of the affected muscle.

HOSPITAL ABUSE AT BRIGHTON

We have on previous occasions called attention to the prevalence of hospital abuse at Brighton. Therefore we are glad to see that by the printed report of the Brighton Committee of the Hospital Reform Association the evil complained of is gradually lessening. The report in question, after referring to the remarks of our Special Commissioner and saying that his report "shows a state of affairs which should demand the immediate attention of all those who are in earnest in wishing to ameliorate the condition of our poorer neighbours and instil into their minds habits of independence and frugality," points out that in the year 1894 the medical staff of the West-street Lying-in Institution of births in Brighton and Hove for that year. In 1897, however, the figures had fallen to 955 and are still decreasing. The reports for 1898 of the various hospitals and of the dispensary have also been published and all show a decrease in the number of external cases. The local committee of the Hospital Reform Association urge upon the local charities to take up the work of reform and they state their opinion that if this were done the subscriptions received would be quite enough for the requirements of the institutions and the poorer classes would be really benefited. The association seems to have met with some success and we can only hope that owing to its efforts the evils exposed by our Commissioner will soon be things of the past.

THE LIVERPOOL SCHOOL OF TROPICAL DISEASES

On April 22nd Lord Foster (as reported in THE LANCET of April 29th) formally opened a special ward of 12 beds (to be called the Samuel Henry Thompson Ward) at the Royal Southern Hospital at Liverpool, when it was pointed out that cases of tropical diseases had been founded at that hospital ever since it had been founded. The arrangements for teaching tropical diseases at Liverpool are now complete. Major Ross has been engaged as special lecturer, Dr Annett as demonstrator, and Professor Boyce, the professor of pathology at University College, Liverpool, as pathologist. It will be remembered that Lord Foster opened the laboratories in October last. The citizens of Liverpool must be warmly congratulated on the business-like manner in which the school has been founded and

forms of incandescence and beauty—and as long as such establishments as those of William exist they will appear again. But the eyes of the authorities are now open as well as those of the public, so that we may fairly hope that masses of houses will cease to constitute a blot on London civilisation and a danger to the innocent of the community.

THE PLAGUE IN HONG-KONG

A CORRESPONDENT writing on April 8th reports that for the week ending April 1st seven cases of plague had been notified in Hong Kong, all of which died. No 9 health district was declared to be infected with plague on April 5th so that houses to-house visitation and cleansing might be proceeded with. Plague is said to be spreading in Formosa both in town and country. The Japanese have the same difficulty about securing reports of cases as we have. Their medical men and nurses are said to be devoted to their struggle with the epidemic.

THE NARROW CONVALESCENT HOME

The Narrow Convalescent Home at Broadstairs was established for the accommodation of children of middle-class people in reduced circumstances. It can receive 50 girls and 50 boys who must not have recently suffered from any infectious or contagious diseases, and must be between the ages of four and 16 years for girls and four and 14 years for boys. The report for 1898, which has just been issued, shows that there has been a steady increase in the admissions of children each year since the opening of the home in August, 1895, the numbers being 661 for the 17 months ending December, 1896, rising to 601 for the 12 months ending December, 1897, and 947 for the 12 months ending December, 1898. From May to August, 1898, there were only a few unoccupied places. The report of the medical officer, Mr Frank Brighman, states that 929 children were discharged during 1898, of whom 647 were then quite well. 69 were greatly benefited, and 193 were improved. The average length of stay of each child was 27 days. The London offices of the home are at 73A, Queen Victoria street, E. C.

THE DIAGNOSIS OF SPORADIC TRICHINOSIS

In the *American Journal of the Medical Sciences* for March Dr Osler has drawn attention to the difficulty of diagnosis in sporadic trichinosis. The symptoms may not be at all distinctive, a large proportion of the cases are no doubt overlooked. The hog is more frequently infected with trichinae in America than in Germany, but disease is less common because few persons eat raw or partially cooked pork. During 20 years hospital practice Dr Osler has observed only five cases, and these in the last two and a half years. In all gastro-intestinal symptoms were not marked at the onset and in only one were they at all severe. All at the onset complained of irregular pains in the muscles, joints, and back. Fever as the symptom most apt to lead to erroneous diagnosis. It is accompanied by headache, stupor, and general symptoms of serious illness. The diagnosis of typhoid fever is therefore suggested. It is strengthened by the diarrhoea. In one case the temperature was very suggestive of typhoid fever. Shortly after admission it reached 104° F., and the diurnal variations for three days were not more than 2° in spite of the spongings carried out under this belief. Erysipelas was noted in two cases, and enlargement of the spleen in three. Erythema diado-reaction was well marked on admission in three cases. In one case there were two suspicious rose spots. There are in trichinosis three features of great value in diagnosis. While in typhoid fever aching of the back and limbs is by no means uncommon, special complaint of pain in the muscles is exceedingly rare.

the charity" annuities calculated at from 4 to 5½ per cent upon the amount of the gift. Any sum from £50 upwards will be received upon these terms and a gift of £1000 will be considered to provide for the future endowment of a bed upon which the donor may at once bestow a name. Instead of themselves receiving the annuity donors may nominate some other person as the recipient, and in this way provision may be made for dependents and others during their lives with an ultimate reversion of a substantial sum to the hospital. Full information will be afforded by the director at the hospital. We fancy that this scheme is altogether a new departure and perhaps some day, if successful, hospital subscriptions will become a recognised quotation on the Stock Exchange. Whatever be the result the idea is ingenious.

THE MERCERS' COMPANY AND ST THOMAS'S HOSPITAL

ON May 4th the Lord Mayor, accompanied by the Lady Mayoress, the Sheriffs, and the principal civic officials, paid a state visit to St Thomas's Hospital and opened a new ward with 20 beds, one half of which bear the name of the Mercers' Company who have provided £10,000 for their endowment. By such liberal use of wealth our hospitals might all be made free of debt and enabled to do all which the really needful cases of the metropolis require without converting them into pauperising agencies.

INFANTILE PARALYSIS AN INFECTIOUS DISEASE

THE etiology of infantile paralysis is still obscure. Some observers have been led to regard it as an infectious disease, though definite evidence of this has been scanty. The occurrence of "family cases" and the simultaneous occurrence of the disease in many neighbouring households have been referred to by some authors. Instances of epidemics of infantile paralysis have been recorded by Colmer,¹ Cordier,² Leegard,³ Médin,⁴ and Caverley,⁵ while examples of its occurrence in families have been noted by Strümpell (two sisters), Hammond (two brothers), Meyer (twin brothers, after measles), and Simon (three cases in one family, two being attacked one day and the third the next day). On the other hand, Gowers says nothing as to its endemic or epidemic occurrence and states that the influence of heredity in the etiology of the disease is slight. In the *Journal of Nervous and Mental Disease* (April, 1899) Dr Frederick A Packard of Philadelphia records the following instance of the occurrence of infantile paralysis simultaneously in brother and sister S and H G—, aged respectively two and a half and one and a half years, were admitted to the Children's Hospital, Philadelphia, on Nov 29th 1898. Four weeks before admission they had both been exposed to bad weather and seemed to have "caught a cold" at the same time. They were members of an apparently healthy family. The older child, S, had always been well and strong except for an attack of cholera infantum when a baby, and seemed to be perfectly well until the exposure and the "cold" above mentioned. For a few days at the outset of his illness the appetite was poor and there was a slight fever, and three days later he was found to be unable to move his left leg. No other portion of the body was affected, and there was no evidence of constitutional disturbance. On admission he was found to be well nourished, with a head of decidedly square shape and a muddy complexion. The pupils were equal and normal, the tongue was protruded

straight, and the face was symmetrical. There was some evidence of rickets in the form of a slight enlargement of the epiphyses and a slightly developed rachitic rosary. The upper limbs and the right lower limb seemed normal in appearance, their deep reflexes were found unaltered and the limbs could be moved voluntarily. The left lower limb was soft and flabby, its temperature was lower than that of the right leg, its knee-jerk was abolished, and it was never moved voluntarily. On the patient standing up with support the left leg remained limp and flaccid, it would not support the body and was swung forward only to a slight degree by the aid of the muscles of the trunk. The response to the faradaic current was almost nil in the paralysed leg. The other patient, H, had also enjoyed previous good health until her present trouble began. The present illness commenced with a "cold" and fever following exposure as in the preceding case. Three days after the exposure, a few hours after her brother's palsy was noticed, she was found to be unable to move her right arm. The palsy of the arm remained complete from the outset and without involvement of any other part of the body. On admission she was found to have the same square shaped head and muddy complexion as her brother. The pupils were equal and normal, the face was symmetrical, and the tongue was normally protruded. There were similar evidences of rickets in the epiphyses and ribs as in the case of her brother. The right arm was motionless and limp, its muscles were soft and flabby, and there was an evident diminution in bulk of the deltoid muscle. Response to the faradaic current was very feeble, especially in the triceps and deltoid. The conditions under which the disease had its onset in both these cases and the simultaneity of its occurrence in the two patients, its febrile character and the supervention of paralysis after three days from the onset of the symptoms, and the occurrence of epidemics under the observations of others as recorded above, all point to the fact that the disease is an infectious one. The absence in the present cases of dietary indiscretion and of other phenomena of intoxication also indicate that its origin is not to be sought in toxins derived from the alimentary canal. F Schultze⁶ has recently reported a case of acute spinal paralysis of sudden onset with palsy involving both arms. 13 days after the onset lumbar puncture was performed and the fluid obtained was found to contain the *Weichselbaum Jüger meningococcus*. It is believed from this and from the other circumstances above mentioned that the infectious origin of infantile paralysis is rendered highly probable.

THE MASSAGE SCANDALS

THE sentence of 12 months' hard labour passed at the London sessions on the man Thomas William Hill Wilson for keeping massage houses as brothels in Jernyn street and Portland street, although termed by Mr McConnell, Q C, the chairman, an "unusual" one, does not in our estimation appear very severe. The fellow, who had an ill record, was making a large income out of the earnings of prostitutes and was also masquerading as a physician, publishing himself abroad as "Dr Wilson," and obtaining patronage for his brothels by giving details in his advertisements of the genuine medical attentions to be obtained in them. The fact that respectable persons may have been deceived by his representations and either lured to sin or blackmailed in return for their credulity forms another reason for an opinion that Wilson's sentence of a year's hard labour does not err on the side of rigour. These things are known to have happened—their possibility, by the way, was pointed out in the medical press some years ago when the word "massage" was not a cover for

In all the animals the tubercle bacillus was demonstrated in the lesions. The placenta of the foetus was unfortunately not preserved for examination. A post-mortem examination was unfortunately held on the mother and she was shown to be free from tuberculous lesions. The disease was confined to the lungs and the lymph glands of the mesenteries. Very few instances of this nature have been published. Among the lower animals, if we except the experimental work, Dr. Ravenel has only been able to find tuberculous calves. In only 17 fetuses have tuberculous lesions been found and in only 12 of these has the tubercle bacillus been demonstrated. To these should be added one stillborn calf and 17 calves under five days old in which the tubercle bacillus was found.

TRAUMATIC MENINGOCOCLE IN INFANTS

A case recently shown by M. Karmisson at a meeting of the Société de Pédiatrie in Paris and reported in the *Journal de Clinique et de Thérapeutique Infantile* of April 27th is interesting in connection with the etiology of meningococle. The patient, an infant, aged 10 months, was born hydrocephalic, but the meningeal expansion which occupied the site of the left parietal eminence did not appear till the third month of life after a fall on the head. M. Karmisson had had another such case which was also attributed to an injury sustained six weeks previously to the appearance of the swelling. M. Lamellogne at the same meeting mentioned several examples of this malformation which had come under his notice and in which the occurrence of a fall with subsequent injury to the parietal bone appeared to him to justify the traumatic theory of causation. At the same time he admitted that hydrocephalus had a predisposing influence.

YELLOW FEVER IN CUBA

ALERTNESS of Cuban medical men have recently been held in Havana for the purpose of laying before Dr. O'Reilly, the head of the American sanitary service in that city, their views on the subject of yellow fever according to a series of questions which had been previously drawn up and circulated. The replies of Dr. Ruelas, which may probably be taken as typical, are published by the *Archivos de la Policlínica*. He does not appear to be enthusiastic regarding the so-called Stiemmer treatment which consists in attempts to render the digestive canal antiseptic and to keep its contents in motion by means of the administration of minute doses of cathartics. He is not in favour of the use of large quantities of bicarbonate of soda, other antiseptics, such as naphthol, salol, and benzoin, but being equally good adjuncts to the bicarbonate of soda. With regard to his own principles of treatment, if he sees the patient within the first three days of the disease he prescribes 30 grams of ipecacuanha in two powders as an emetic, and six or eight hours after it has acted 15 grams of calomel combined with a similar quantity of jalap in two powders, one to be taken an hour after the other. In this way the digestive canal is washed out and cleansed. If persistent vomiting should occur the stomach is washed out and in order to clear out the intestine a soft rubber tube is introduced as far as possible and an intestinal douche of warm water or of a solution of bicarbonate of soda is administered. In case the patient is not seen until after the third day and before the conclusion of the fifth the calomel and jalap powders only are given. Afterwards antiseptics—perchloride of mercury, salol, benzoin-naphthol, or naphthol—are prescribed, and, of course, milk diet is insisted upon until convalescence. Regarding the question

THE LANCET, August 14th, 1899, p. 29.

OPERATIVE INJURY OF THE THORACIC DUCT

of mortality Dr. Ruelas says "it varies greatly, being sometimes below 15 per cent and at others as much as 60 per cent," generally speaking, it may be put down as 25 or 30 per cent. Persons not acclimatized should reside away from Havana, especially during their first year. They should be very careful to avoid everything likely to irritate the digestive apparatus, and especially the liver, and to avoid all kinds of excess. They should not take alcohol, except in great moderation, and should wear suitable clothing. No over-ripe fruit or fruit not in season should be touched. Bicarbonate of soda should be taken easily and a saline purge every two or three weeks. Exposure to the sun's rays for any length of time must be guarded against. Special caution is needed in the spring.

INJURIES of the thoracic duct are rare. The *Boston Medical and Surgical Journal* of April 13th, 1899, contains an interesting paper on the subject by Dr. F. B. Lund. In most of the reported cases crutches of the chest and similar injuries were the causes, leakage of chyle into the pleura or abdomen producing chylous pleurisy or chylous ascites. In 1865 Hutchinson collected 17 cases in which only one patient recovered. Injuries of the duct in the neck were usually to be associated with injuries of the great vessels and were generally fatal, but in recent years, since the complete operation for cancer of the breast has been the rule, in a large number of cases the subclavian triangle has been dissected. In operations on the left side the duct has been injured in a moderate number of cases. Cushing, in the *Annals of Surgery* for June, 1898, has reported nine cases in which the thoracic duct was injured in operating for cancer of the breast or in dissecting in the neck tuberculous or other glands. Strange to say only one was fatal. Two occurred in the Johns Hopkins Hospital—in one the duct was sutured, which prevented the leakage, in the other the leakage appeared several days after the operation, the wound having healed by first intention. A tumour appeared in the wound and on incision yielded a milky fluid which poured out for several days but was stopped by gauze packing. Of 35 cases in which the complete operation was performed on the left breast in the Johns Hopkins Hospital the thoracic duct was injured in two. Why do such injuries heal so well? Possibly the duct is not completely cut off but only wounded, so that healing naturally occurs. Also a not infrequent abnormality is that the duct is double near its outlet, so that one division may allow for a time profuse leakage, later the chyle may pass by the other. Finally, Cushing suggests that the lymph may ultimately be taken up by the right thoracic duct. He advises when the left subclavian triangle is dissected to tie all lymphatics. If the thoracic duct is wounded a provisional ligature is to be placed round it and an attempt made to control the leakage by packing. If the packing is unsuccessful the provisional ligature is to be tied and the duct occluded in the hope that by an anomalous branch or by diversion of the current to the right subclavian vein a collateral circulation will be established. As to the dangers of closing the thoracic duct Sir Ashley Cooper found that in dogs sudden occlusion was always fatal. In cases in which there has been pressure on the duct by tumours a venous condition below the point of pressure, chylous ascites, chylous pleurisy, and other untoward results have followed. In the light of the reported cases Dr. Lund would wait very long before attempting to close the duct. He would prefer to let it leak on the chance, which is very great, that it will heal rather than tie a provisional ligature. He relates a case of cancer of the breast in which a very large number of discoloured enlarged glands surrounded the axillary vein and extended

its connexion with University College is an especially wise proceeding. At the inaugural dinner in the evening Lord Lister expressed his sympathy with the feeling at Liverpool that it would be a hardship if men who had studied at Liverpool under the best conceivable conditions which could exist in the British Isles should be compelled to go to London to study there. Such an arrangement would act most prejudicially to the Liverpool School, as it would naturally occur to most men that they might as well go to London at once. We are pleased that Lord Lister spoke so plainly on this subject and have no doubt that Mr Chamberlain will give every consideration to these views now that they have been expressed by such a distinguished representative of our profession. As we have repeatedly pointed out, the variety of tropical diseases at the Seamen's Branch Hospital at the Albert Docks is not nearly so large as it is generally supposed to be. Lord Lister also said that he was commissioned by Mr Chamberlain to say that the proposed compulsory arrangement was only made for a single year, and that when the year had expired he would reconsider the question. Like Lord Lister, we feel confident that at the expiration of a year, this requirement will no longer be insisted on by Mr Chamberlain.

LUCCHENI REDIVIVUS.

WHEN in these columns¹ we took formal leave of the assassin of the Empress of Austria we dwelt on the megalomania which had proved to be the determining motive of his crime. "Withdrawn from the public gaze and the gratification he drew from this position" we saw him "collapse at once into the 'hystero epileptoid imbecile' of the criminal anthropologist"—all his revolting cynicism and defiant self-sufficiency gone, reduced, indeed to the morbid type of degenerate humanity which he so strikingly represented. Twice since then he has attempted, in sheer *taedium vitae*, to commit suicide and has had in consequence to be more vigilantly watched lest by carrying out this purpose he might baffle for ever the efforts of the authorities to ascertain whether he committed the murder *proprio motu* or was simply the agent of an anarchist plot. Within the last few days, however, his moral condition has undergone a change confirmatory, in a significant degree, of the diagnosis which found vanity or megalomania at the root of his crime. The Cantonal Judge d'Instruction, in pursuance of the attempt above indicated to ascertain his possible complicity with others, visited him in his cell and approached the subject with what seemed to himself due dexterity or caution. At once the previously downcast and abject creature brightened up, his eyes sparkling with gratified self-importance. "I giornali riparlano di me?" ("So the journals are talking of me again?") he exclaimed interrogatively, and then the judge was aware that he had erred, as in Scott's great romance Mr Sharpitlaw erred when, in trying to get out of Madge Wildfire the knowledge she possessed of the ringleader of the Porteous Mob and his hiding place, he inadvertently touched the spring of vanity and put the cunning half-witted creature on her guard. There was, however, no receding from the step which he had incautiously taken and he disclosed the object of his visit. Luccheni thereupon, just like his counterpart in the "Heart of Midlothian," dallied with his interlocutor, smiling at his reminiscences of the crime, assuming airs of reticence, even indulging in self-contradiction to tease, if not torment, his judicial antagonist. One admission, however, he dropped in this improvised fencing match—an admission which he could not be induced to make on his trial—he really had accomplices in the preliminaries leading up to the assassination.

But at this point his memory suddenly failed, he confessed that these accomplices were two in number but their names or their "ubicazione" (whereabouts as to origin or habitual residence) he could not recall. Now, it appears that a few minutes before he committed the crime an elderly man with a full white beard was seen in his company on the Quai du Mont Blanc, that this individual pointed out his victim to him and thereafter was lost sight of, having cleverly divested himself (doubtless) of his hoary "hirsute appendage" and other disguises. Nothing more, we understand, was elicited by the judge at the visit referred to, but (for us at least) the point of present interest is the confirmation of the assassin's megalomania and the prescriptions which such a diagnosis suggests in dealing with others of his type. "Vanity being in most cases their guiding motive they should, under every legal safeguard and formality be brought to justice in private and be visited with its severest penalty in private likewise." We have said before—and we repeat it now—that medico-psychology must reinforce the civil law to a greater extent than it has hitherto been allowed to do if justice is to meet the anarchist assassin on equal or effective terms. An admonition in this sense was given at the International Congress of Criminal Anthropology held at Geneva in the September of 1896, but it was treated, with scant respect, by the jurists who represented Russia, Germany, and France particularly, as a "fad" of the Subalpine Medical School. Two years afterwards, almost to a day, the Empress of Austria's murder near the very spot where the congress met gave that school its "sombre revanche." Let us hope that the meeting of the same congress at The Hague in August next will reveal the "juridical mind" as less impervious to the experience of the sister profession on a subject that demands the serious and sympathetic cooperation of both.

FATAL TUBERCULOSIS IN A CALF

IN the Proceedings of the Pathological Society of Philadelphia, New Series, Vol II, No 6, is an interesting paper by Dr M P Ravenel entitled "A Case of Fatal Tuberculosis in a Calf." The writer very rightly points out that cases of congenital tuberculosis are rare enough to have more than a passing interest, and though this method of transmission occurs so seldom that it may practically be excluded from our calculations in considering the spread of the disease each undoubted case is instructive and worthy of record. The case which came under the notice of Dr Ravenel is as follows. During the latter part of 1898 a cow well advanced in tuberculosis was sent to the Veterinary Department of the University of Pennsylvania. On Dec 23rd, 1898, without any assignable reason, she aborted, the fetus being about seven months old. A careful examination was made and, so far as gross changes were concerned, nothing abnormal was found except in the liver, on which were seen two whitish nodules of about one sixteenth of an inch in diameter. These suggested a tuberculous origin, though much doubt was felt as to their nature. They were removed and crushed in a sterile mortar and emulsified. With the emulsion three guinea pigs were inoculated, two by the intra-peritoneal method and one subcutaneously. One of these guinea pigs died on Feb 6th, 1899, the second on Feb 16th, and the third, inoculated subcutaneously, was killed by chloroform on Feb 22nd, 1899. The first two showed general tuberculosis of the abdominal organs with involvement of the inguinal and lumbar glands. The lungs were not affected. The third guinea-pig had an abscess at the point of inoculation of about the size of a filbert, filled with caseous material. There was a general tuberculous adenitis, with caseous changes in many of the glands. The lungs, liver, spleen, and omentum showed marked signs of tubercle, and a portion of the peritoneum, about one and a half inches long by three-quarters of an inch wide, was studded with

¹ THE LANCET Dec. 10th, 1898, p. 1564

there was also pain in the sacrum. There were no physical signs. Lateral compression of the pelvis increased the pain. Rest in bed, anodyne, and turpentine embrocations were prescribed. The patient rapidly improved and returned to work in a week. But the pain had not completely disappeared and was re-awakened by pressure on the joint and by movements. There were also radiated pains which extended to the popliteal space, they manifested themselves when he stooped, sat down, knelt, or turned his foot to the left. If he sat for long he had pain on getting up. At the internal part of the left buttock a small ecchymosis was discovered. A month later there was no sacro-iliac tenderness but the patient complained of weakness in the lower limbs and of pain in the posterior parts of the thighs where there appeared to be some paralysis of the muscles. A week later he could stand and walk without pain. Dr Galliard thought that in addition to the sacro-iliac sprain there had been traction on some branches of the sacral plexus, a complication which had not been described by Dr Deshayes.

A MEDICAL HERO

Heroism is not, we are glad to say, uncommon, and very possibly the most heroic deeds are those of which the least is heard. Golden deeds are done in various fields—in battle, in shipwreck, in civil life, in plague-stricken cities, and in the sick room. As striking an instance as any recently reported came out owing to the application of a lady to "presume the death" of her father as

having been lost in the *Stella*. She and her father were standing on the deck and her father made an appeal to some passengers in a boat to make room for his daughter. One man promptly climbed back on to the sinking ship and went down with her. No one knows his name, but his example will surely never be lost sight of. There was not much romance and no excitement in this act to make it more easy for the unknown to risk his life. And this "accident" of non-romance and want of excitement is often especially notable in deeds of medical heroism. Such acts are generally concerned with circumstances which to the lay mind would be positively repulsive and which even to the trained professional man are, to say the least of it, unpleasant. On May 3rd a man named John Menzies of Sunderland swallowed some phosphorus paste in some beer. The police were informed and Mr. R. J. Burns was sent for and came armed with a stomach pump. The pump however, was unfortunately out of order and so Mr. Burns passed the time and acted as a pump himself—i.e., he sucked the poisonous contents of Menzies's stomach through the tube with his own mouth. Menzies recovered temporarily but has since died and Mr. Burns suffered from marked symptoms of phosphorus poisoning but is now better. A more unpleasant or repulsive thing to do we can scarcely conceive and the members of our profession may well be proud of numbering Mr. Burns among their number.

THE TREATMENT OF OPHTHALMIA NEONATORUM

The interest which is associated with the painful ophthalmia of infants in the minds of most practitioners is not nearly so great as it is. It is true that its cause and effects as well as the principles of its treatment are generally well understood, nevertheless, the subject still possesses in its clinical aspect something even of the attraction of novelty. The reason for this is, no doubt, to be found in the fact which method in management and the personal quality which develops this have much to do with the course and issue of the disease. It is mainly this fact that impresses the reader of a paper published by M. Kahl in the *Journal de Clinique et de Therapeutique Infantile* of April 27th. The writer believes in the well-established reputation of

nitrate of silver as a local remedy while he regards with no favour the use of mercurial solutions. What is of at least equal importance, he perceives the advantage of soothing applications such as the compress of bone water and of avoiding superfluous manipulation in applying the caustic. The strength of this latter varies from 1 to 3 per cent means of a drop-tube. The use of the stronger solution is followed as usual by washing with 5 per cent of distilled water. It is applied by M. Kahl on cotton-wool to the everted eyelids, but frequently also by means of a drop-tube. Irrigation is a method less practised in purulent ophthalmia than it deserves to be. It implies, of course, the use of weak solutions only and careful regulation of the frequency with which they are used, but it is of much service in the less advanced stages of the disease without corneal abrasion even where there is considerable purulent discharge. It possesses, moreover, the advantage of obviating much manual interference with a tender and inflamed organ, and it may be employed by a mother or nurse under medical supervision. Irrigation with very weak permanganate of potash or lime-water solution is freely employed by M. Kahl, who goes further in this direction than most practitioners would care to follow him, bathing with three-quarters of a litre at a time. In this part of his treatment he certainly errs, in our opinion, on the side of thoroughness.

THE CONTROL OF THE MANUFACTURE OF MEAT PREPARATIONS

We have been gratified to receive communications from several well known makers of meat extracts in which the views which we expressed in an annotation in THE LANCET of April 22nd as to the control of the manufacture of meat preparations are fully endorsed. Indeed, we are so glad to learn that in many factories a staff of practical chemists and food analysts is retained whose duty it is to test every batch of material by the best scientific methods. "Any plan to supplement these self-imposed precautions," writes one firm to us, "by a State-controlled system of examination of food stuffs in general would not only meet with no opposition on the part of manufacturers of reputation but be welcomed as an official condemnation of their statements to the public." Nothing could be more satisfactory of unit material. "Nothing could be more satisfactory than this or could afford better assurance to the public. It will be remembered that the recent propositions upon which we based our arguments for the necessity of control related to an incident in which it was shown that the purveyors of so-called 'table delicacies' had a mass of putrid liver and offal on their premises, and the inference was irresistible. But in justice to the respectable makers of meat extracts properly so called it should be stated that the fate of this rotten material would most probably have been paste in the form of what the manufacturers are pleased to call "table delicacies," perhaps as *pate de foie gras*, sausages, ham and chicken, or even blatter paste. We do not believe that the true meat extracts on the English market are in any sense open to reproach. Good wholesome meat is plentiful and cheap enough and the manufacture of meat essences and extracts on a liberal scale is a benefit of no mean importance to the profession and to the community at large. We still maintain that the Government should institute a system of control calculated to stamp out meat pastes or "table delicacies" having the vile origin which we have indicated, and to bring the productions of honest makers into the prominence which they deserve.

The house surgeons of St Thomas's Hospital who held office during the period in which Sir William Mac Cormac

up to the clavicle. The omo-hyoid muscle was divided and the whole subclavian triangle, internal jugular vein, and subclavian arch were cleaned. It was recognised that there was great danger of wounding the duct but there was no evidence of leakage. On the second day after the operation there was pain in the neck and on the fourth day there was a tumour and milky fluid leaked between the stitches. The wound was opened and packed with gauze. After four days the leakage ceased. Convalescence did not appear to have been affected.

MENTAL NURSES

THE care of patients suffering from temporary or permanent mental disorders is frequently a source of anxiety to medical men, and the existence of institutions for the supply of male and female attendants especially trained to nurse such cases supplies a great want. Many of the nursing institutions have on their staff nurses who have had the required training, but their number is limited. Among the best conducted of the special institutions for the supply of mental nurses is the one known as the "Mental Nurses' Coöperation," the offices being situated at 1, New Quebec-street, Portman square. All the nurses, male and female, have been specially trained to the requirements of mental patients. Another favourable circumstance is that all the nurses are total abstainers, this being most important in cases of dipsomania where for obvious reasons it is an advantage that the attendant should take no form of alcohol. Especially is this the case in travelling appointments where temptations to indulge in the prohibited beverages are particularly numerous. It is also useful to the practitioner to know where a capable attendant can be at once procured in cases of acute mania so that skilled treatment can be promptly applied until, should it be necessary, the patient has to be removed to an asylum, and another condition in which such training is essential is that of delirium tremens occurring in the well-to-do where home treatment can be carried out.

ARSENIC IN WOOL

THE question has been raised more than once in these columns as to the maximum quantity of arsenic which might be permitted in a given area of woollen material without injury to health. The occurrence of arsenic in undyed wool in very minute quantities is referable, not to any process of manufacture but to the fact that sheep require to be dipped in arsenical wash in order to destroy "tick." Other washes free from arsenic are also employed but their effect does not appear to be so satisfactory, for in addition to effectually destroying parasites an arsenical dip improves the fleece. Unfortunately it is impossible by several scourings and by other processes with which the elaboration of wool is concerned to remove absolutely the arsenic. It appears to adhere most tenaciously to the fabric and since it resists all attempts at extraction by ordinary means the probability is that the minute trace of arsenic thus left in the wool does not lead to injury to health. The fact that the arsenic is held so closely would seem to indicate that a compound is formed which is quite insoluble in which, therefore, the arsenic has been probably rendered non-injurious. It is, indeed, not improbable that the trace which occurs is combined with the sulphur of the wool, and sulphide of arsenic is innocuous. Wool is said to consist chiefly of an albuminoid sulphur-containing substance termed keratin, and it is not unreasonable to suppose that the residual trace of arsenic contained in wool after the most drastic washing is the insoluble compound of arsenic with sulphur. If such be the case there can be little objection to this excessively minute trace which can only be discovered by an exceedingly delicate chemical analysis. In Sweden there is a law against the

sale of woollen fabrics containing arsenic in any quantity beyond a minute trace. The question remains, What is a minute trace? The limit fixed is 0.0009 per cent. On one occasion a carpet was condemned because it contained one-thousandth part of a grain of arsenic in 16 square inches. It is difficult to conclude that such a minute trace of arsenic could cause any harm, especially as it most likely exists, as we have just pointed out, in an insoluble and not easily volatilised form. It can hardly be concluded that a minute trace of arsenic which resists all attempts at extraction by powerful scouring processes can give rise to injury to health. The question is an important one and one which has given rise to considerable trouble in the English woollen trade. As far as we know no definite evidence has been forthcoming of injury having been caused by the occurrence of this residual trace of arsenic in wool. Obviously some limit should be placed upon the amount and it seems to us that this could easily be arrived at by estimating the average amount of arsenic which remains in wool after repeated washing in strong extractive agents.

"SMALL-POX AND VACCINATION"

IT is, we believe, an open secret that the masterly article on small pox and vaccination in the last number of the *Edinburgh Review* is from the able pen of Mrs. Garrett Anderson, M.D. Paris. There is a peculiar appropriateness, both of time and authorship, in the appearance of this article, coming as it does so closely on the heels of a paper on the same subject in the March number of the *Contemporary Review* by Mrs. Anderson's sister, Mrs. Fawcett. Barely has so good an illustration of the natural sequence of the tale and its antidote been presented to an observant world. And Mrs. Anderson's article is the more welcome because, as we happen to know, the editor of the *Contemporary Review* when approached with an offer of a reply in his own columns to Mrs. Fawcett's clever but insidious attack on vaccination expressed his regret that he was unable to find room for one. It is some years since society was edified by the spectacle of the divergencies of two gifted brothers, John Henry and Francis Newman, who, like Corydon and Thyrsis in the eclogue, *cantare paros et responderé parati*, so well enforced the fact that community of birth and early training is quite consistent with marked discrepancy of intellectual convictions in later years. And the two no less gifted sisters who have thus recently descended into the *certainum magnum* of the vaccination controversy, which has hitherto been left to the rude struggle of male athletes, we may hope will succeed in infusing into it a courtesy of thrust and parry to which it has been for the most part a stranger.

SACRO-ILIAC SPRAIN

At the meeting of the Société Médicale des Hôpitaux on March 10th Dr. Galliard called attention to this form of sprain which is hardly recognised by surgeons. It is usually accompanied by sprain of the symphysis pubis. In 1886 Dr. Deshayes of Orleans described six cases under the title of "pelvic sprain." A man, aged 31 years, in making an effort to lift a heavy cask felt an acute pain in the posterior part of the pelvis on the left side accompanied by a kind of cracking in the same region. He fell down and had to be carried home. On the following day he went to hospital and was cupped, the diagnosis evidently being lumbago. He could walk only with great difficulty leaning on the arm of an attendant or on two sticks. The pain was especially violent when he supported himself on his left leg. He could not sit, in bed no position was comfortable and he could not sleep. When examined on the fifth day the seat of pain was definitely localised in the left sacro-iliac joint, pressure on all accessible points of this joint produced acute pain,

was actively connected with the hospital and school will entertain him at a dinner to be given at the Café Royal on Wednesday, May 24th, in honour of his third year of tenure of the post of President of the Royal College of Surgeons of England. The whole number of past house surgeons of the period amounts to 130, of these 13 are dead and 20 are in various parts of the world abroad. Of the remainder scattered over the United Kingdom it is hoped that all will be present, as coöperation in the scheme has been practically unanimous. The chair will be taken by Mr G O Franklin of Leicester as the senior house surgeon on the list.

THE following 15 candidates are recommended for election into the Royal Society.—Professor William F Barrett, Mr Charles Booth, D Sc, Major David Bruce, R A M C, Mr Henry John Horstman Fenton, M A, Mr James Sykes Gamble, M A, Professor Alfred Cort Haddon, M A, Dr Henry Head, Professor Conwy Lloyd Morgan, F G S, Mr Clement Reid, F G S, Professor Henry Selby Hele Shaw, M Inst O E, Dr Ernest Henry Starling, Professor Henry William Lloyd Tanner, M A, Mr Richard Threlfall, M A, Mr Alfred E Tutton, B Sc, and Professor Bartram Coghill Alan Windle, M D Dub.

THE annual dinner of the Royal Institute of Public Health will be held in the Victoria Hall, Hotel Cecil, on Wednesday, June 7th, at 7 P M, when the Harben Gold Medal will be presented to Lord Lister. A number of distinguished guests have accepted invitations to be present. Tickets (1 guinea, inclusive of wine) are to be obtained from Mr Henry O Jones, honorary secretary of the institute, 197, High Holborn, W C.

THE annual dinner of the Indian Medical Service will be held at the Hotel Cecil on Thursday, June 8th, at 7 45 P M, when Surgeon General Sir W Guyer Hunter, K O M G, Honorary Surgeon to the Queen, will preside. Officers intending to be present should communicate at an early date with the Honorary Secretary, Mr P J Freyer, 46, Harley-street, W.

AN inaugural dinner in aid of the foundation fund of the Medical Graduates' College and Polyclinic is announced to take place at the Trocadéro Restaurant, Piccadilly circus, on the evening of Wednesday, June 14th. The chair will be taken by Sir John Lubbock.

H R H THE DUKE OF CAMBRIDGE will preside at a festival dinner in aid of the rebuilding fund of the Alexandra Hospital for Children with Hip Disease, Queen square, Bloomsbury, at the Hotel Cecil on Tuesday, June 20th.

ON Thursday, May 18th, a brass tablet erected to the memory of the late Sir B W Richardson, formerly President of the British Medical Temperance Association, will be unveiled at the London Temperance Hospital.

THE Prince of Wales's Hospital Fund has received a donation of £5000 from Mrs Brydges Williams.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on May 8th, His Grace the Duke of Northumberland, President, presiding. The following were elected members: Mr A Cooper, F R C S Eng, Mr A W Porter, Mr S Stephenson, and Mr T Uzielli. The special thanks of the members were returned to Mr Hugh Dewar for his donation of £200, to Mr Thomas H Sowerby for his donation of £5 5s, and to Mr John H Usmar for his donation of £50 to the Fund for the Promotion of Experimental Research at Low Temperatures.

GARBAGE MONGERS

BY FREDERICK WILLIAM ALEXANDER, L R C P EDIN,
M R O S ENG,
MEDICAL OFFICER OF HEALTH OF POPLAR AND BEOMLEY.

Canned Foods—The Significance of the "Soldering Points"—A Suggestion

ON account of the recent revelations and convictions in regard to canned foods it may be useful and interesting to the medical profession to understand something respecting the significance of the "soldering points" upon cans containing articles of food. I know of no book explaining the subject and one cannot apply, for obvious reasons, to manufacturers for any such knowledge, so that anything learnt by attending at a police-court and chatting to experts and listening to them under examination and cross examination may benefit the community by being made generally known. In the Journal of the Sanitary Institute, April, 1898, there is an article upon "Poisoning by Canned Foods, Hints on its Prevention," by Dr J Brown; medical officer of health of Bacup which is well worth reading by everybody. Dr Brown speaks of the plating of the cans, but he does not mention anything concerning the utility of the soldering points, although he does say "It has been stated that some American firms reseal blown tins. The tins then have their former normal concave appearance again." Again, in hints to consumers he states "Cans doubly sealed by soldering are suspicious."

Articles of food which are to be canned as a rule are put boiled to allow for a certain amount of swelling before being put into the can, and as further cooking, with sterilising, is done whilst in the can it is essential for the soldering to be done strongly, and when fixing on the top of a can in order to seal it down it is necessary to have a hole in this piece of metal forming the top to allow of the escape of the expanded air and the steam generated by the soldering process, otherwise the solder will spit and will not flow properly to form a good and neat joint. When the top has been soldered on and the prick hole shut with solder the can is placed in a water bath or a steaming apparatus. The temperature being raised the contents expand and cause the cans to "blow," which means that the ends of the can become convex. The can is then taken out of the apparatus and the prick hole is unsoldered by the application of a hot iron, when about one cubic inch of heated air escapes. The hole is soldered up afresh and the can put back again into the water bath or steaming apparatus and the sterilising and cooking processes completed. In evidence it was pointed out that for blowing purposes during the bathing and steaming processes, instead of unsoldering the prick hole, some firms prefer making a second hole either at the side or at the other end of the can. The reason one understands for this is that when cans are hot and their prick holes have been unsoldered and the contents are steaming out the holes cannot be soldered up again so neatly, hence the blow-hole is made at the other end, which is made the bottom of the can when labelled, or the hole is made on the side and is covered afterwards by the label.

In unsoldering or making a second hole to relieve pressure in order to create a vacuum, it may be necessary on account of the contents of a can having shifted and blocking up such a hole, and thereby preventing the air escaping, to make another hole with a "prod," which may account for more than one soldering point. With some canned foods it will be noticed that inside the can immediately under the soldering point is a small metallic plate, the object of which is to obviate the necessity of making another hole as this plate prevents the contents of the can blocking up the soldering point which when unsoldered allows the can to blow so as to obtain a vacuum. In the steaming apparatus on shelves certain foods are cooked in the cans with the blow-hole unsoldered, but when the water bath is used the cans are packed together and they are completely soldered down. It was pointed out in evidence by an expert that the blow hole is not really necessary, but firms do this in the first or low heat stages of the bathing or steaming processes to allow air

THE STUDY OF TROPICAL MEDICINE

BETWEEN three and four hundred gentlemen attended a festival dinner of the Seamen's Hospital Society which was held in the Grand Hall of the Cecil Hotel on Wednesday evening last May 10th.

The toasts of "The Queen" which was received with musical honours, and "The Prince and Princess of Wales and the other members of the Royal Family" were proposed by the Right Hon. J. CHAMBERLAIN, M.P., the chairman. The Marquis of Lorne proposed, "The Navy, Army, and Auxiliary Forces," which was replied to by Admiral Sir Anthony H. HOBBS and the Marquess of Lansdowne. The Secretary of State for War, referring to the Royal Army Medical Corps, said that the army was a small one but its liabilities were immense. The most formidable foe that the British soldier had to encounter was tropical disease. Lord Lansdowne reminded his hearers that in the Irish campaign in round figures there were 1000 admissions to hospital from gunshot wounds and the injuries usually sustained during a campaign while there were 11 000 admissions from fever and dysentery. Of the deaths there were 100 from wounds and injuries but nearly 600 from diseases of a tropical kind.

Mr. GAVIN AND SOVER, J.P., proposed "The Houses of Parliament." Lord Loch in responding, asked for support for the Colonial Nursing Association. Sir WILLIAM PRESTLEY referred to Lord Lansdowne's interest in the Medical Department of the Army and remarked that his connection with establishing the Royal Army Medical Corps had made him so popular with medical officers that there was a desire to have his portrait framed in every mess room where they were assembled. The Establishment of the London School of Tropical Medicine and the Endowment of Victoria and Albert Docks." Mr. CHAMBERLAIN said that was the greatest work of civilisation our greatest enemy was the insidious attacks of a deadly disease which weakens where it does not kill and which shortens the lives and careers of the ablest and most energetic of those who go out to represent us in these countries. The problem before us was manifold. We had to seek out and make clear the history and origin of these diseases. We had, if possible, to find a cure for them, and with those objects we had to extend the study of these diseases, and to create, if may be, a school of trained practitioners and investigators, so that in future scientific research may go hand in hand with practical medicine. He referred to the aid which had been given by Lord Lister and the Royal Society to the work of Major Ross, M.S. in India and that of Dr. Patrick Manson (medical adviser to the Colonial Office) and his predecessor (Sir Charles Gage Brown), and to that modern as that hospital would be increased to 50 beds. When this enlargement had taken place and the necessary buildings had been erected the course of procedure would be somewhat as follows. The Colonial Office and the other offices which had dependencies in the tropics under their charge would give a preference in their selection of medical officers for those colonies and dependencies to the gentlemen who had gone through a course of special study in connection with the subject of tropical diseases in one of the great medical institutions of the country. This course of study might extend over two or three years and be given in any of the medical institutions of the United Kingdom. After that study had been completed and the necessary certificates and degrees had been conferred it would be expected of the candidates selected for the service that they should take advantage of seasons of tropical medicine and practically learn the treatment of tropical medicine and the treatment of fevers desolating our colonies and the dependencies in many tropical countries and should make the tropics livable for white men would do more for the world, more for the British Empire, than the man who added accumulations of house refuse at times got rid of by

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT

OF THE LOCAL GOVERNMENT BOARD

On the Sanitary Circumstances and Administration of the St. Dogmales Rural District, by Dr. H. DEAN SWERING.

The Local Government Board, we learn from this report, are not on general grounds in favour of the division of sanitary districts, amongst a plurality of medical officers of health and are directing special inquiry into the sanitary circumstances and administration of districts so divided. In course of these inquiries inspection has been made of the rural district of St. Dogmales in Pembrokeshire, an area of about 12 miles by 17 miles, comprising 17 parishes five of which lie along the coast-line of St. George's Channel. This rural district has 2431 inhabited dwellings and its population at the last census was 9125. Its assessable value is £27676. It is a but with small urban aggregations of population at St. Dogmales, Cilgerran, Newport, and a few other villages. Probably on account of its size and its highly character the district has been subdivided for sanitary purposes. Dr. Phillips of Cardigan being medical officer of health of one half, and Dr. Harard of Newport the health officer of the other half. Such advantages as this subdivision presents however, Dr. Swering considers to be more than balanced by the difficulties in the way of joint action by the two health officers and by the smallness of the salary which the district council pays in each instance. The Inspector recommends the appointment of a single medical officer of health who should be in closer relation with his authority than is at present the case, and remunerated on a scale which would permit frequent inspections of different parts of his district. From the account given of the sanitary circumstances and history of administration in St. Dogmales there seems to be a pressing one, and it is to be hoped that the efforts of the single medical officer if appointed, will be more successful than those which have been made in vain by his two predecessors. The housing of the poorer classes in the place appears often to be of a most wretched description. Small cottages some only of one room, badly dilapidated with floors of beaten earth below the level of the surrounding ground and without thorough ventilation appear to be common. It is often difficult for a local authority to deal satisfactorily with houses of this sort, but it is at least in its power to see that new dwellings erected in the district comply with reasonable sanitary requirements. But at St. Dogmales they have no building by laws and no plans of houses are ever submitted to the district council before they are erected. Frequent opportunities of pollution of streams by the prevailing methods of sewage and excrement disposal. Such drainage as there is in the several villages of the district consists merely of rubble drains discharging into neighbouring watercourses, and by means of the drains or otherwise the streams in the neighbourhood have in many cases become the common sewers of the district. Even accumulations of house refuse are at times got rid of by

[MAY 13, 1899]

487 deaths, but in 1898 the cases fell to 1379 and only 276 of them ended fatally. "A new hospital was completed last year at Sohag and new hospitals are under construction at Assiout and Ohibin el Kom." In addition to the above several other minor ameliorations are recorded, but Lord Cromer feels constrained to add in conclusion "In spite of the progress which has been made some of the provincial hospitals are, I regret to say, still in a very bad condition. They will be taken in hand gradually as funds are available."

It is in connexion with the ordering of cemeteries and mosques that of late years the sanitary authorities in Egypt have been most successful. In each case a complete, and happily also a silent, revolution has been most advantageously effected. Formerly the people used to bury their dead at their doors, utterly regardless of the danger to the living, while the so-called purifying arrangements which were attached to most of their mosques were simply stinks of unutterable foulness. For obvious reasons it was extremely difficult and even dangerous to attempt reform in either direction, but by dint of "great care and judgment" the most bigoted even of the Moslem community have been brought to admit the reasonableness of the proposed innovations. Writing to Lord Cromer with reference to the mosques of Upper Egypt Sir John Rogers observes "It was remarkable to receive in many places—towns as well as villages—the expression of thanks from leading inhabitants for the sanitary improvement effected in the mosques. The measure when first initiated was purely tentative and it was by securing the cordial coöperation of the native classes, official and private, and at the same time insisting on the necessity of sanitary reform, that success became assured. The cost in all the villages has been borne by the community." No fewer than 94 mosques were purified during the year 1898, a vast gain to sanitation, while in the same space of time 118 cemeteries were transferred from dangerous to innoxious sites. At first the opposition to the removal of the initial cost was very strong, but it is cheering to find that the new cemetery is completed and the initial cost paid the village inhabitants are the first to recognise the advantage conferred on them by having a decent cemetery at a suitable distance from their habitations."

Several other matters of interest to members of the medical profession are discussed by Lord Cromer in this admirable and exhaustive report, but any further remarks which we may have to offer must be deferred to a future occasion.

THE PREVENTION OF TUBERCULOSIS

(Continued from p 1045)

LONDON

The first statutory meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on May 4th at 20, Hanover square, W. The Earl of Derby was in the chair. Dr StClair Thomson read the report of the Organising Committee which showed that 1252 members had already been enrolled and there were 25 branches formed or in course of formation in the provinces. Mr Malcolm Morris the treasurer, read the financial report which showed that the association could rely on a sum at the present moment of £1100. The Chairman moved the adoption of the financial report and also that 30 gentlemen recommended by the Organising Committee for election be elected as the first council of the association. Sir William Broadbent said that it was hoped that before the next statutory meeting was held there would be a conference of representatives from all parts of the country. Dr Clifford Allbutt, in moving a vote of thanks to the Organising Committee, suggested that it would be a good thing if chairs of comparative pathology were established. The President of the Royal College of Physicians of London, Dr W S Church, said that the duty of the profession was to direct public interest to the movement against tuberculosis. A conference of delegates from various metropolitan boards of guardians was recently convened by the Union of St Saviour, Southwark, and met on April 20th at the offices of the City of London Guardians. The conference was to consider the subject of tuberculosis. Mr T Cooksey, of the parish of St Saviour, who was voted to the chair, said that the question of tuberculous patients in Poor law infirmaries was a most important one. Large numbers of

such patients were treated at the Poor law infirmaries, but with the existing accommodation it was impossible to treat them properly. It remained to be seen whether the Poor law unions were sufficiently impressed with the gravity of the case to take common action whereby some improvement might be brought about. Mr F Redman (St Saviour) read a paper on Phthisis Patients under the Poor law and concluded by moving the following motion—

That, having regard to the large number of cases of tuberculosis disease which find their way into establishments under the care of the Poor-law guardians and the danger of infection incurred by non-tuberculous patients it is desirable that special institutions should be established in the country to which all hopeful cases of tuberculosis disease should be removed.

This was seconded by Mr F J Rilly of Mile-end. Mr. Lindow of Woolwich thought that they could treat cases of phthisis quite well in Poor law infirmaries provided the centres of infection and something should be done either to reduce their number or to see that they were conducted under better conditions. Dr Potter of Kensington said that out of 93 cases of phthisis admitted into Kensington Infirmary last year there were only 15 which could have been sent to a sanatorium. He thought that a trial sanatorium for 200 selected cases might be provided. After some further discussion Mr Redman agreed to modify his motion as follows—

That, having regard to the large number of cases of tuberculosis disease which find their way into establishments under the care of the Poor law guardians it is desirable that the Local Government Board should make an exhaustive inquiry into the cause and treatment of the same.

This was carried unanimously.

TUBERCULOSIS AND MUNICIPAL CORPORATIONS.

The corporations of Blackpool, Bootle, Derby, Darwen, Leeds, Manchester, Salford, and Stockport recently proposed some rules for the prevention of tuberculosis. These rules were prepared by the Local Government Board and the Board of Agriculture and accepted by the council of the Central Chamber of Agriculture, with some exceptions, mainly arguing that the clauses ought not to apply to cows unless affected with tubercle of the udder. A meeting of the Parliamentary Committee of the Central Chamber of Agriculture was held on April 18th, at which Mr W H Long was present, and it was decided to withdraw opposition to the rules if they were limited in the above sense. The corporations accepted this compromise. The most important clauses of the rules are Clause 2, which imposes a maximum penalty of £10 for the sale knowingly of milk from cows suffering from tuberculosis of the udder, Clause 3, imposing a maximum penalty of £5 upon a dairyman knowingly keeping a cow with a tuberculous udder with other cows in milk, Clause 4, rendering notification of cows suffering from, or suspected of, tubercle of the udder obligatory, and Clauses 5 and 6, providing for inspection of samples of milk and power to take the same and giving power to corporations to suspend a suspected milk supply.

TROWBRIDGE

An important meeting was held at the George Hotel, Trowbridge, on April 22nd. The object of the meeting was the formation of a West Wilts Branch of the National Society for the Prevention of Consumption and Other Forms of Tuberculosis. Captain Chaloner, M P, was in the chair and there was a good attendance of medical practitioners and others. Mr Murray Gray explained the objects of the association. The branch was duly formed and the meeting proceeded to elect patrons and officers. Among the patrons was Mr W H Long M P, the Minister of Agriculture. It was proposed to hold a public meeting shortly at which the Minister of Agriculture should be asked to preside.

STOKE BY NAYLAND

An estate of 94 acres at Stoke-by-Nayland in Suffolk has been purchased by a Yorkshire gentleman, Mr Walker of Dewsbury, with the object of erecting on it a large hospital for the treatment of phthisical patients. Mr Walker's daughter, Dr Jane H Walker, will be the resident physician. This lady has already acquired considerable experience in this department of practice, having for the last eight years been at the head of a small sanatorium for tuberculous cases at Caus Farm Denver, in the county of Norfolk. It was from observing the benefits obtained from the open air treatment of phthisis in Switzerland that Dr Jane Walker was induced to found in England an institution conducted on similar lines.

London showed a further decline from that recorded in the three preceding months, among the various sanitary areas in this disease showed the highest proportional prevalence in Westminster, St Saviour Southwark, Rotherhithe, Wands-
worth, Greenwich, and Plumstead. The Metropolitan Asylums Hospitals contained 2088 scarlet fever patients at the end of April against 2637, 2535, and 2272 at the end of the three preceding months, the weekly admissions averaged 177, against 226 and 186 in the two preceding months. The prevalence of diphtheria in London during April showed a further marked decline from that recorded in recent months, this disease was proportionally most prevalent in Clerkenwell, St. Saviour Southwark, St George Southwark, Newington, Bermond-
sey, Lambeth, Camberwell, and Greenwich, and Green-
wich. There were 994 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of April, against 1358, 1368, and 1159 at the end of the three preceding months, the weekly admissions averaged 107, against 166, 172, and 127 in the three preceding months. The prevalence of enteric fever in London showed a slight further decline from that recorded in recent months, among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, St George-
in-the-East, Lambhouse, Dolphin, and St. Saviour Southwark. The Metropolitan Asylums Hospitals contained 124 enteric fever patients at the end of April, against 249, 215, and 148 at the end of the three preceding months, the weekly admissions averaged 17, against 27 and 19 in the two preceding months. Dysentery was proportionally most prevalent in Westminster, St Giles, Bethnal Green, Mile End Old Town, and Lambeth sanitary areas. The 23 cases of paratyphoid fever notified in London during April included three in Hackney and two each in Kensington, Hammersmith, Chelsea, St Pancras, and Lambeth sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending April 23rd, the deaths of 6579 persons belonging to London were registered, equal to an annual rate of 18.0 per 1000, against 17.0, 20.3, and 22.2 in the three preceding months. The lowest death rates in the various sanitary areas were 9.4 in St. Olave Southwark, 11.8 in St. Martin in the Fields, 13.1 in Battersea, 13.2 in Hampstead, 13.3 in Stoke Newington, and 13.6 in Lewisham (excluding Fenge), the highest rates were 22.2 in Newington, 23.2 in Bermondsey, 24.4 in St. George in the East, 25.0 in St. George Southwark, 25.5 in Holborn, 25.6 in the four weeks of April 555 deaths were referred to the principal zymotic diseases in London, of these, 159 resulted from measles, 27 from scarlet fever, 108 from diphtheria, 212 from whooping-cough, 27 from enteric fever, 32 from typhus, and one either from small pox, typhus, or diphtheria. These were equal to an annual rate of 1.6 per 1000, against 1.5, 1.6, and 1.9 in the three preceding months. No death from any of these zymotic diseases was recorded in the month in Stoke Newington, in the other sanitary areas they caused the lowest death rates in Paddington, St. James Westminster, Hampstead, St. Luke, Wandsworth, and Plumstead, and the highest rates in Hammersmith St. George in the East, Limehouse, St. George Southwark, Newington, and Lee. The 159 fatal cases of measles were less than half the corrected average number in the corresponding periods of the 10 preceding years, this disease showed the highest proportional fatality in St. George Hanover square, Hackney, St. George in the East, Limehouse, Greenwich, and Lee sanitary areas. The 27 deaths referred to scarlet fever were 36 below the corrected average number, the mortality from this disease showed no marked excess in any of the sanitary areas. The 108 fatal cases of diphtheria were 34 below the corrected average number, this disease showed the highest proportional fatality in Strand, City of London, Limehouse, St. Saviour Southwark, St. George Southwark, Newington, and Lewisham sanitary areas. The 212 deaths from whooping-cough were 59 below the various sanitary areas in Kensington Hammersmith, and St. George in the East, Little End Old Town, and Islington.

HEALTH OF DUBLIN

which were referred to whooping cough, 16 to measles, ven to diphtheria, five to diphtheria, three to scarlet fever, and to other diseases, five to diphtheria, and 52 deaths resulted from these principal zymotic diseases, against 53 and 76 in the two preceding weeks. These 52 deaths were equal to an annual rate of 17 per 1,000, which was slightly above the mean rate last week from the same diseases in the large English towns. The fatal cases of whooping cough, which had been 13 and 22 in the two preceding weeks, declined again to 19 last week, of which eight occurred in Aberdeen, five in Glasgow, and three in Aberdeen. The deaths from measles, which had increased in the three preceding weeks from 13 to 30, declined to 16 last week, of which 14 were recorded in Glasgow. The five fatal cases of diphtheria exceeded the number registered in any recent week, and included two in Glasgow and two in Aberdeen. The deaths from scarlet fever, which had been four and five in the two preceding weeks, declined to three last week, of which two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 119 and 117 in the two preceding weeks, further declined to 109 last week, and were 23 below the number in the corresponding period of last year. The causes of 34, or more than 6 per cent, of the deaths in these eight towns last week were not certified.

The death rate in Dublin, which had declined in the three preceding weeks from 33.4 to 29.7 per 1000, further fell on 24.8 during the week ending May 6th. During the past two weeks the rate of mortality in the city has averaged 29.5 per 1000, the rate during the same period being 17.2 in London and 17.7 in Edinburgh. The 166 deaths registered in Dublin during the week under notice showed a decline of 33 from the number in the previous week, and included seven which were referred to the principal zymotic diseases, four resulted from whooping cough, two from "fever," and one from diphtheria, but not one either from small-pox, measles, scarlet fever, or diphtheria. These seven deaths were equal to an annual rate of 10 per 1000, the zymotic death rate during the same period being 1.5 in London and 1.6 in Edinburgh. The total cases of whooping cough, which had been three and eight in the two preceding weeks, declined to four last week. The deaths referred to different forms of "fever," which had been two and three in the two preceding weeks, declined again to two last week. The mortality from diphtheria corresponded with that recorded in the preceding week. The 166 deaths registered in Dublin last week included 18 upwards of 60 years, the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Ten infant cases and six deaths from violence were registered, and 54, or nearly a third, of the deaths occurred in public institutions. The cases of four, or more than 2 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1899

complete statistics relating to sickness and mortality during April in each of the 43 sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 62 per 1000 of the population, estimated at 4,646,752 persons in the middle of this year. In the three preceding months the rates had been 92, 85 and 67 per 1000 respectively. The rates were considerably below the averages in Paddington, Hampstead, St. Martin in the Fields, Strand, Lec. and Pimlico, while they showed the largest excess in Westminster, St. George Southwark, Green, St. Gaviour Southwark, and Greenwich sanitary areas. Including two in Islington and one each in Marylebone, Wembley, Poplar, and Camberwell, two small parishes were admitted into the Metropolitan Asylums Hospitals during April, and three remained under treatment at the end of last month. The prevalence of scarlet fever in patients was admitted into the Metropolitan Asylums Hospitals during April, and three remained under treatment at the end of last month.

being thrown into streams Dr Sweeting enumerates other shortcomings, such as faulty slaughter houses, filthy cow-sheds, and absence of provision for disinfection or isolation of cases of infectious illness. It is to be hoped that his report may be followed by adequate remedial action on the part of the local council concerned.

REPORTS OF MEDICAL OFFICERS OF HEALTH

City of Edinburgh Sanitary District—By the usual method of estimation the population of Edinburgh amounted in 1898 to 295,628, but Sir Henry Littlejohn gives reasons for thinking that this number under estimates the actual population. The birth rate for the year was 27.38, and the general death rate 19.6 per 1000. The density of the population in the several wards of the city ranged from 12.9 to 146.6 per acre, but, as Sir Henry Littlejohn points out, these relations convey to the ordinary reader a very imperfect idea of the actual conditions obtaining in each ward. As regards the prevalence of diphtheria and enteric fever in the chief divisions of the city the following table is of considerable speculative interest.

	Diphtheria.	Enteric fever	
New Town ..	9.5	10.4	cases per 10,000 of population.
Old Town ..	7.3	6.7	" "
Southern District	12.0	6.1	" "
Portobello ..	5.3	1.1	" "

Sir Henry Littlejohn draws attention to the relative freedom of the "Old Town" as compared with the incidence upon the more modern "Southern District." The main feature of interest in 1898 was, however, an outbreak of typhus fever, and a chart is furnished in the report before us showing that this disease has to some extent manifested itself in the city since 1880. During 1898 there were 79 cases of this disease, 36 being males and 43 females, the cases occurring between the beginning of October and the end of December. As regards age distribution a noticeable feature was the large number of children who were attacked. At the commencement of the outbreak certain cases escaped recognition, and had this not been the case probably fewer attacks would have occurred. Sir Henry Littlejohn thinks that the disease was imported into Edinburgh about the middle of August, and he is inclined to regard the holding of a wake in connexion with the body of a man who not improbably died from typhus fever as one of the means of spreading the disease. During the course of the outbreak Sir Henry Littlejohn was, he states, much struck with the fact that, save at short distances, the disease evinced but little infective power. One of the inspectors engaged in the removal of the cases contracted the disease, and a staff nurse, who slept near the typhus wards but had otherwise no known connexion with them, succumbed to an attack. The fatality rate amounted to only 11.2 per cent.

Eccles Urban District—Dr J. H. Crocker in dealing in his current annual report with the influence of schools in occasionally spreading infectious disease reports that owing to the occurrence of five cases of diphtheria amongst children attending the St. Michael's Schools he examined the throats of all the children present in the schools on a certain date. Out of 164 children thus examined no less than 145 had uninfamed throats and he gives instances where children notified as suffering from diphtheria must obviously have been affected with the disease while still at school. The corporation have decided that all dairy cattle purchased by them shall be tested by tuberculin. Out of 27 cows tested in this way in October 1898, by the veterinary surgeon to the corporation, 12 or 44.4 per cent reacted.

Chesterfield Urban District—Dr Moredith Richards reports that Chesterfield has now been created a hospital district under the Isolation Hospitals Act, 1893. The financial assistance offered by the Derbyshire County Council towards the structural expenses of hospitals erected in the county has induced the corporation to proceed under the Isolation Hospitals Act rather than under the Public Health Act. It appears that the Borough Hospital Committee, in whom the duty of providing isolation accommodation is now vested, have agreed with the North Derbyshire Hospital Committee, which represents the district surrounding Chesterfield, to erect a joint hospital of 30 beds at Penmore. Further steps will be taken when the county council can obtain the necessary loans. As regards the endemicity of enteric fever in Chesterfield, Dr Richards observes that the experience of 1898 has confirmed his previously expressed opinion that the specific infection of polluted soil in the neighbourhood of dwellings through the

agency of the execrable privy midden system is the main source of mischief. The average infantile mortality for the last six years in Chesterfield has been 189 per 1000 births, and Dr Richards furnishes a table in his report comparing this rate with that during the same period for England and Wales and the surrounding towns of Nottingham, Leicester, Sheffield, and Derby. Of these Leicester, with an average rate of 195, is the only one which exceeds Chesterfield. Dr Richards has constructed an infantile life table for Chesterfield from the figures of the last six years, and he contrasts the results thus obtained with the table which appeared in the fifty-fourth annual report of the Registrar General and which gives the infantile mortality figures for three rural counties (Herts, Wilts, and Dorset) conspicuous for their low rates and three selected towns (Preston, Leicester, and Blackburn) conspicuous for their high rates. We have not space to analyse the figures, but it may be mentioned that out of a theoretical 100,000 children born in Chesterfield there would have died during the first two months of life 7840 infants, as against 7077 in the "three towns" and 4473 in the "three counties."

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In 33 of the largest English towns 6719 births and 3616 deaths were registered during the week ending May 6th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 23.1 to 17.7 per 1000, further fell last week to 16.5. In London the rate was 16.0 per 1000, while it averaged 16.9 in the 32 provincial towns. The lowest rates in these towns were 9.8 in Derby, 10.6 in West Ham, 10.9 in Cardiff, and 13.1 in Blackburn, the highest rates were 19.8 in Salford, 20.3 in Manchester, 20.6 in Liverpool, and 22.3 in Plymouth. The 3616 deaths included 339 which were referred to the principal zymotic diseases, against 384 and 383 in the two preceding weeks, of these, 114 resulted from whooping cough, 91 from measles, 57 from diphtheria, 28 from diarrhoea, 25 from scarlet fever, 22 from "fever" (principally enteric), and two from small pox. No death from any of these diseases were recorded in Brighton or in Wolverhampton in the other towns they caused the lowest death rates in Croydon, Plymouth, Halifax, and Gateshead, and the highest rates in Bolton, Manchester, Salford, and Burnley. The greatest mortality from measles occurred in Salford, Manchester, and Bolton, and from whooping cough in Cardiff, Birkenhead, Burnley, Preston, Salford, Oldham, Bradford, and Hull. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 21 in London, six in Leicester, five in Leeds, five in Sheffield, four in Birmingham, and three in West Ham. Two fatal cases of small pox were registered in Hull, but not one in London or in any other of the 33 large towns, and no small pox patients were under treatment in any of the Metropolitan Asylums Hospitals on Saturday last, May 6th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2139, against 2144 and 2131 on the two preceding Saturdays, 219 new cases were admitted during the week, against 163, 189 and 228 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 277 and 294 in the two preceding weeks, declined again last week to 249, and were 74 below the average. The causes of 38, or 1.1 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Nottingham, Bradford, Leeds, and in 15 other smaller towns; the largest proportions of uncertified deaths were recorded in Cardiff, Liverpool, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 18.1 and 21.1 per 1000 in the two preceding weeks, declined again to 18.5 during the week ending May 6th, but was 2.0 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12.8 in Leith and 14.9 in Aberdeen to 18.3 in Edinburgh and in Paisley and 20.1 in Glasgow. The 564 deaths in these towns included

Newington The 27 deaths referred to entered fever were within three of the corrected average number, this disease showed the highest proportional fatality in Marylebone and St George-in-the-East sanitary areas. The 32 fatal number in conclusion, it may be stated that the aggregate mortality in London during April from these principal zymotic diseases was nearly 36 per cent below the average infant mortality in London during April, measured by the proportion of deaths of children under one year of age to registered births, was equal to 119 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Marylebone, Stoke Newington, St Giles, St. Luke, St. Olive Southwark, and Lewisham, and the highest rates in Kensington St Martin in the Fields, Holborn, Shoreditch, Limehouse, and St George Southwark.

THE SERVICES

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel Richard D Bennett retires on retired pay, Captain Richard B Kelly is promoted to the rank of Major. Lieutenant-Colonel H C Kirkpatrick has arrived from Aden on privilege leave. Major J G Black is posted to the station hospital, Belfast. Major McCreey embarks for Dublin for duty.

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Lieutenant-Colonel Thomas Cayzer resigns his commission. Surgeon Major D L Anderson to be Surgeon Major.

VOLUNTEER CORPS

Artillery 1st Hampshire (Southern Division, Royal Artillery) Edmund Napier Close to be Surgeon Lieutenant Royal Engineers (Volunteers) 1st Hampshire Surgeon Lieutenant Henry Fulton resigns his commission, and is appointed Second Lieutenant (Supernumerary) 2nd Volunteer Battalion the Cameronians (Scottish Rifles) Surgeon Lieutenant J L London to be Surgeon Captain 1st Cadet Battalion, the Manchester Regiment. Lancel James Edward Remah to be Acting Surgeon.

VOLUNTEER OFFICERS' DECORATION

The Volunteer Officers' Decoration has been conferred upon Surgeon Lieutenant-Colonel Henry Colgate of the 2nd Sussex Volunteer Artillery.

THE PHILIPPINES

There does not seem to be much doubt now that the end of the insurrection in the Philippines is near at hand. The insurgents have been badly beaten in every engagement with the American troops and have practically already surrendered. Therefore President McKinley's belief that peace will soon be arranged appears to be well founded. The next question which will engage the attention of the United States Government will be the arrangement for safeguarding the health of the American army of occupation until matters have become settled and the new form of government has been securely established. Admiral Dewey is shortly to return to America and to be succeeded in his command of the naval squadron by Admiral Watson. The attention of the American nation will soon be occupied with questions of climatology, hygiene, and public health measures in respect of their new possessions.

DEATHS IN THE SERVICES

Surgeon General Robert Cockburn, late Bengal Medical Service, on April 30th, in his seventy-fifth year.

MEDICAL SERVICE IN THE Soudan

A despatch with its enclosure, from Major-General Lord Kitchener of Khartoum, G C B, K C M G, Sirdar of the Egyptian Army, dated Omdurman, Feb 8th, 1899, to Lord Cromer, contains the following passage: "Captain Jennings, B A M C, S M O, showed great gallantry and devotion, discharging the wounded as they fell under fire, the quality of which is recorded for by the casual return. He was admirably seconded by Muzin Arai Latif Effendi Ahmed. This officer has already done very valuable service at Harko when the whole of the Cavalry and Camel Corps were down with malarial fever, from which he also was suffering, since the action Captain Jennings and his staff have been uncasingly at work."

Correspondence.

"Anal albumin pattern."

"A CRITICISM OF THE MORE COMMONLY EMPLOYED TESTS FOR ALBUMIN IN URINE"

To the Editors of THE LANCET

Sirs,—I have to apologise to Mr Cammidge that by mistake I did not observe the statement in his article that he had employed quantitative methods in his investigations. In his courteous reply he is quite right in assuming that I observed the sentence referred to. I would not have written as I did.

With regard to our disagreements I regret that Mr Cammidge did not add to the value of his work by publishing the details of processes, precautions, and weighings which chemists expect in such a case. My simple albumins to be tested in urine. If I pursue the investigations I will certainly follow the synthetic plan. That is to say I will examine the delicacy of the tests when applied to solutions of albumin in water at first, I will then make, say, a 2 per cent solution of urea in water and use that solution to dilute a solution of albumin of known strength, examining the action of the tests for albumin at each dilution. Stimulantly the action of the tests in

SIR HENRY NORBURY, K C B
SIR HENRY FREDERICK NORBURY, M D, K C B, Inspector-General of Hospitals and Fleets, and Director-General of the Medical Department of the Royal Navy, has been placed on the retired list from May 7th. Sir Henry Norbury was born in 1860 and entered the Royal Navy as surgeon in 1889. During the Zulu war of 1879 he was principal medical officer of General Sir O Pearson's column and was afterwards principal medical officer of the Naval Brigade with General Crealock's column and was several times mentioned in despatches. Sir Henry Norbury will still continue to hold the appointment of Director-General.

THE ROYAL MILITARY TOURNAMENTS
The annual display at the Royal Agricultural Hall, Islington, promises to be, as in indeed of late years it always has been, a most attractive one. The pageant "Warriors of Britain" has been arranged to show the evolution of the British soldier during the past three and a half centuries and the typical periods which have been chosen are—"The Wars of the Roses," "Newbury," and "Tudor," always popular. The combined display—the "Khartoum" (Omdurman) will represent the Storming of Passer Sala, 1876. The tournament will open on Thursday, May 25th, and close on June 8th.

SEVERE SCAOTRIA FOR SOLDIERS
The result of the experiment in providing accommodation during the coming summer at seaside garrisons, to which we have already called attention, will be awaited with interest. If the invalids and convalescents be judiciously selected and the system properly worked it may be confidently expected that the experiment will be attended with excellent results and be a real boon to our sick and convalescing soldiers. The local arrangements will, of course, be left largely in the hands of the general commanding and the principal medical officer of the respective districts.

THE MEDICAL PROFESSION AND THE PUBLIC SERVICES
That with the fighting in Samoa and that in Uganda, the unsettled state of affairs in regard to the Transvaal, the China convention question, and the settlement of the Soudan, the Government of this country must have abundance of occupation for, and be largely in need of, the services of members of the medical profession at the present time and in the near future. The augmentation of the Navy will also call for a corresponding increase in the naval medical service.

VITAL STATISTICS OF LONDON DURING APRIL, 1899

[MAY 13, 1899.]

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1899
(Specially compiled for THE LANCET)

Buxton, May 6th 1899

"EXTRA-UTERINE FERTATION"
To the Editors of THE LANCET

Sirs,—On referring to the report of my case "A Provincial Surgeon," will find that it is the five years' sterility and not the tubal pregnancy which I consider was produced by the use of means to prevent conception.
I am, Sirs, yours faithfully,
Plymouth, May 2nd, 1899.

"AN IMPORTANT POINT UNDER THE INFECTIOUS DISEASES (NOTIFICATION) ACT"
To the Editors of THE LANCET

SIRS,—I have only just now seen in THE LANCET of April 15th a letter signed "M. B. O. M." on "An Important Point under the Infectious Diseases Act." A similar point arose between me and the local sanitary authority and I referred the matter to the Local Government Board. Their decision was that the authority must pay the whole amount claimed, though a considerable portion of the claim was for certificates rendered some year or more previously. I based my claim on the ground that each certificate was in itself a claim for payment and was in effect due at once and that no further account was necessary. The sanitary authority accordingly paid the whole account and directed their inspector in future to pay the fee of 2s 6d for each certificate returned by me to him.
I am, Sirs, yours faithfully
H. G. ARKSTRONG
Wellington College, Berks, May 8th, 1899.

THE DISTRIBUTION OF SERUMS
To the Editors of THE LANCET

Sirs,—Can you inform me under what conditions local sanitary authorities are allowed to distribute to medical practitioners the anti diphtheritic serum? Is there any limit as regards the position of the patient?
I am, Sirs, yours truly,
April 20th, 1899
** No sanitary authority has any power to distribute to medical practitioners any drugs or remedial measures except under one or other of the two following conditions. First, this effect under the Public Health Act, 1875 on the ground that England is threatened with some formidable epidemic, or infectious disease. This power has hitherto been limited to outbreaks of cholera which have invaded England. Secondly, in connection with the treatment of persons removed to hospitals for infectious diseases provided by sanitary authorities. But if a medical officer of health is of opinion that the use of an anti-diphtheritic serum amongst persons who have been, or are likely to be, exposed to the infection of that disease would tend to prevent its further spread the sanitary authority have full power to supply the serum to him for use under his supervision as a means of prevention. The real distinction is between the prevention of infection and the treatment of an already existing case of disease.—ED. L.

TELEGRAMS AND THEIR ANSWERS
To the Editors of THE LANCET

Sirs,—I have been corresponding with the Post Office authorities for some months endeavouring to get them to allow me and my neighbours to hand stamped telegrams to the more eager boys who constantly pass our door on the way to the district office. This the late and the present secretaries of the General Post Office refuse to allow on many

MEDICAL AID INSTITUTIONS AND CLUB PRACTICE
To the Editors of THE LANCET

SIRS,—It seems to me that the profession is now ripe for reform in reference to both of the above. The General Medical Council has done good work in doing away with the unqualified assistant and now his day is over we have a chance of asserting ourselves. But we cannot do this unless we have union and stress put upon those who will not unite. Individually we can do nothing but fight a losing game. So as to form a juvenile club. I mentioned the terms on which I should take them and shortly after got notice of the parent club leaving me as another medical man was taking their lads at less. I hold another where precisely the same thing happened and the same medical man stepped in, with the exception that the parent club remained with me and the lads were taken by him at less again. Another club, also of men only, wanted me to take females. I declined absolutely and got notice with the intimation that Dr. So and So would take them. This medical man lived four miles away and set up a branch practice here in charge of an unqualified assistant on the strength of this appointment. Medical aid institutions rob us of many fees and take away many of our patients who are perfectly satisfied with our charges. Still some neighbourhood who is perhaps better off than themselves or some agent tempts them by the offer of medical attendance at less price than they were paying (and able to pay) shillings, and in some cases pounds before. You, Sirs, know all this, you have advocated our cause too long and entered into the subject too minutely not to know that want of combination allows medical men to do work which, I believe, three-fourths of them are sick of. Further, to a conscientious medical man there is no profit in it. The advance in our medical and surgical knowledge demands increased expenditure. The Compensation Act than ever less the law requires our aid, besides, it causes more work as more trivial injuries come under observation than formerly. The Notification Act does the same lest we are caught napping over some unfeeling cases which we have not notified and the people themselves are better able to pay. The Medical Defence Union and other unions have been successful and I am glad to say I have long been a member of the former though I have not requested its help. I think so highly of their work that the words, in my opinion, "member of Medical Defence Union or member of such and such a union," should have a place after such members name in the Medical Directory to let each man know where he would be almost sure to find and support in the case of a union. I am writing about Could not a similar union be formed with local branches and to hold meetings on the subject, where the arrangements which have already been adopted with success could be put before general practitioners, and to formulate such plans as would largely to do away with medical aid companies? I am aware that such a union would require money, but I think that many practitioners would gladly subscribe to get rid of the occupation which holds so many in its grasp. The Medical Defence Union or the other unions have done good work for the modest subscription requested from their members. Is it possible that these unions, or one of them, could—the subscription being increased by consent—do this further work? It seems to me that the organizations already formed would be a large membership and though perhaps not all of these enter into a very large number of combinations would need much strength of membership and funds to carry on, stronger should help the weaker. Such a combination would

presence of common salt, phosphates, uric acid, &c, when present alone in aqueous solution containing albumin should be noted. After an investigation of the effect of such single additions on the delicacy and working of the tests the next step would be to go on to mixtures, and the final results would be obtained by diluting albumin solution by urines of various specific gravities. I believe that in such a way only could reliable and comparable results be obtained. Anyone who has had experience of the great care and prolonged washing necessary to obtain decimal places in the percentage results of a simple inorganic analysis can hardly refrain from scepticism regarding many of the results obtained from a complex fluid of varying composition such as urine. I am, Sirs, yours faithfully,

Glasgow, May 6th, 1899.

WALTER COLQUHOUN

THE APPLICATION OF THE OPEN-AIR SYSTEM OF TREATMENT TO THE INSANE

To the Editors of THE LANCET

SIRS,—During the past year or two I have seen some apparently very good results in ordinary forms of insanity from open air treatment conducted somewhat on the Nordrach system, but of course modified to suit individual cases according to their mental condition. For the information of those who are not conversant with the Nordrach system and for the guidance of those who may wish to adopt the system, in whole or in part, in this country, I subjoin the following few remarks concerning it.

The life at Nordrach may be said to be a natural life carried out under unnatural conditions. It is natural inasmuch as it is the life which primitive man would lead, for primitive man lived entirely in the open air and habitually, no doubt, over ate himself, whereby it is supposed that he lived to a fabulous age in perfect health. It is unnatural inasmuch as it is entirely foreign to our modern ideas of living, for when it rains we like to keep dry, and when there is wind we like to keep out of it, and we like to eat enough, but we do not like habitually to eat to excess. At Nordrach the patient under treatment rises about 8 A.M. and receives a cold douche at a pressure of about three atmospheres, followed by hard friction. Each room at Nordrach is fitted with its own douche and differs in this way from other German and from Swiss sanatoria where there is generally a special douche room. After a substantial breakfast the patient goes for a specially prescribed walk at a specially prescribed pace and walks till one hour before lunch and during that one hour he must rest quietly on the couch or bed in his room. The windows are conspicuous by their absence, only the open spaces remain. Thus complete rest and fresh air are assured at the same time. Lunch, or rather dinner, is a most formidable meal. The medical officer sits at the middle of the table. He carves for each patient and there the patient sits until he has eaten everything—and hard work the patient finds it is to do so. After this he will rest a short time, for he hardly feels capable of walking. Then follows another prescribed walk at a snail's pace and another hour's rest in the bedroom before supper at 7 P.M., which is nearly as substantial as dinner. There is more walking after supper and the patient is in bed by 10 P.M. Nothing of any kind is allowed between meals and nothing is wanted. Patients put on weight at a most surprising rate and completely alter their appearance, they soon look the healthiest of the healthy. The sanatorium itself consists of two or three small houses in which nearly all the rooms are bedrooms. Sitting rooms are not required. The dining room is in an entirely separate building, the windows of which are never closed except in the worst of weather. Milk or beer is drunk at meals, but milk is hardly necessary as so much weight can be put on without it and it is often better to keep milk in reserve in case of a relapse when it is most valuable.

I am induced, but with much diffidence, to suggest a more extended use of the open air system than has hitherto been the custom in the treatment of the insane, for it is generally admitted that the insanities as met with at the present day are usually associated with debility, malnutrition, lowered vitality, nervous degeneration, exhaustion, and kindred bodily conditions. The open air system, where it is possible to employ it, seems to me for these reasons alone to be clearly indicated. But there are more cogent reasons than any

of those already given for the fullest employment possible of the open air system. It is a well known fact that a very close and intimate connexion exists between tuberculosis and insanity. The curious in such matters will find this subject exhaustively discussed by Dr. Clouston of the Royal Edinburgh Asylum in a paper read by him so far back as the beginning of the year 1863 and published in the *Journal of Mental Science* for April of that year, and the subject of phthisical insanity is fully dealt with recently in Tuke's *Dictionary of Psychological Medicine*. Some of the statistics given by Dr. Clouston to prove the very important part which tubercle plays in the insanities are startling and I take the liberty of quoting them. Post-mortem examination revealed the fact that out of a total of 463 deaths in one asylum tuberculous deposit was found in the bodies of 282 patients, the percentage being 51.7 in males and 73 in females. Thus it is seen that the proportion of persons dying in asylums with tuberculous deposit in various organs of the body very much exceeds the proportion found similarly affected in the general population. The tuberculous condition in the insane cannot always be ascertained during the lifetime of the patient, it often seems to remain latent or to run its course without giving active external evidence of its presence. A final sudden breakdown in pulmonary phthisis is not uncommon and it is perhaps still more common to ascertain the existence of tubercle in various organs for the first time in the post mortem room.

I am, Sirs, yours faithfully,

West Malling Kent, May 10th, 1899.

JAMES ADAM

NASAL TREATMENT IN ASTHMA

To the Editors of THE LANCET

SIRS,—I was somewhat surprised during the very interesting debate on "Asthma in Relation to Disease of the Upper Air passages" at the Laryngological Society on Friday last to find that no speaker, with the exception of Dr. Dundas Grapt, laid any great stress on the very frequent presence of the gouty diathesis in the asthmatic. I venture to suggest that it is not impossible that some of the failures related may be due to neglect of that factor.

Somewhat of a sceptic as regards the value of nasal treatment in asthma my conversion was brought about by means of what appeared to be a typical case of gouty asthma, most severe attacks frequently alternating either with eczema or articular gout. Persistent gout treatment under the guidance of several eminent physicians and at various spas had failed to give more than temporary relief, but since the fortunate discovery and thorough removal of several nasal polypi four years ago there has been no real attack of asthma. In a letter received last week the patient says "Although wonderfully well I find that if I neglect my precautions regarding dietary there is at once a tendency to irritation in the nose and to slight difficulty of breathing." This case, in addition to a number of others working out on similar lines, makes me think that there is frequently a double source of irritation present.

Another circumstance which has arisen in five cases has impressed me a great deal. All were treated by skilled operators. In three cases polypi were removed, in two there was radical treatment of hyperæsthetic patches on the nasal mucous membrane, but in all recurrence of asthma took place after a very little time. All came under bath treatment for gout, which was followed by the use of a carefully planned dietary devised with a view to aiding uric acid elimination. There was in each case more or less improvement in the asthma but there was much left to be desired. I referred them to rhinologists and in every case the nasal lesions were found to have recurred. Removal of these was followed by relief so extraordinary as to amount to a practical cure and although from one to three years have elapsed all these patients have remained well except one who from time to time takes fits of dietetic unrighteousness. It suggests itself as a possible explanation that as in almost all cases of this type there is marked failure to excrete the normal amount of uric acid by the kidneys (examination of the 24 hours urine by the Gowland Hopkins process always showing a decrease of from 10 to 30 per cent) there may be an attempt at vicarious elimination by the nasal mucous membrane or at any rate a deposit in a part the vulnerability of which has become increased. A certain amount of irritation may be thus set up, leading to the renewed growth of polypi, &c. Careful observation has convinced me that as

but I think that many more would join, as the subject of my letter is always before most middle and working class practitioners, and their number must be great, while the business proper of the unions does not so immediately and so frequently touch every practitioner, not that I wish to underrate their valuable work in any way. I have already spoken to the great good they have done. But if they could not take up this additional work—and I hope they could—could another union not be formed to do so? I believe I have seen that the council of the Medical Defence Union will have a motion brought before it to accept no more members who further the work of medical aid institutions. Could not the medical societies throughout the land aid the movement by a similar resolution? By so doing they would help to elevate the dignity, the prestige, and the status of a profession so very many members of which have bartered away its liberties, its advantages, and its high tone for a mess of pottage. I have written a very long letter and must apologise for taking up so much space, but I should like to see something come of it, and perhaps, though my suggestions might not be adopted, they might lead to other and more practicable ones, if so I should be better pleased.

I am, Sirs, yours faithfully,

May 6th 1899.

GENERAL PRACTITIONER

MR T W RUSSELL, M.P., AND THE VACCINATION ACT, 1898

To the Editors of THE LANCET

SIRS,—In your report of the recent dinner of the Sanitary Institute Mr T W Russell, Parliamentary Secretary of the Local Government Board, is stated to have said that the Vaccination Act of last session had "to a large extent abolished stational vaccination" and that "compulsion and all its effects were abolished." What does Mr Russell mean? The Act has abolished stational vaccination not "to a large extent" merely but completely. The Local Government Board have refused to allow the vaccination stations to be maintained even in a locality so exceptionally situated as Liverpool. Nobody should know better than Mr Russell that compulsion is not abolished. A parent may, if he likes, obtain exemption from vaccination on terms, the terms being a payment of a variable amount and attendance at a police-court. If he does not like to obtain exemption on these terms he will be compelled to have his child vaccinated or to pay a single penalty. In either case there is compulsion from which escape may be purchased by a money payment, as was the case before the Vaccination Act was passed. The only difference is that now the terms of exemption are somewhat easier. At recent petty sessions at Midhurst three defendants were fined respectively 10s., £1, and £1 10s. for not having their children vaccinated. What is this but compulsion? It is strange that the Parliamentary Secretary of the Local Government Board should be apparently ignorant of these facts.—I am, Sirs, yours faithfully,

May 8th 1899

A CONSTANT READER

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Pasteur Institute Committee—Progress of the Plague— The Importation of Jigger

AN occasional spasm of energy is displayed by the promoters of the Pasteur Institute for India. The central committee have at last ventured to pass a resolution asking the Government for an annual grant equal to the average cost during the last three years of sending soldiers bitten by rabid animals to Paris. At the same time the central committee decided to inform the Home Department that if this grant were given the central committee would establish an anti-rabic institute if the Government would allow the services of one of their officers to take charge thereof. All these conditional offers and acceptances between outside bodies and the Government drag on indefinitely and the fulfilment of this scheme is almost as far off as ever. Why does not the Government itself take the matter in hand and establish a Pasteur department of the medical service? They could easily pick out a promising, young, and well qualified officer and send him to Paris for instruction. The third resolution passed by the

central committee was to invite the Secretaries in the Home and Military Department to become members of the committees. This is probably not of much value, but these little contestries seem to be necessary in India. I am glad to hear, however, that Colonel Fenn, surgeon to the Viceroy, has joined the central committee as more energy and new blood are wanted for his movement.

I am able to record a considerable improvement in the course of the plague. There is a continued and marked decline in Bombay, where recently from 1000 to 1500 deaths have been occurring regularly every week. There is a general improvement elsewhere in the Bombay Presidency with the exception of Karnohi, where the outbreak still remains severe and does not give any indications of immediate abatement. In the Jullunder district of the Punjab a few cases have occurred, but the outbreak is not serious. The most curious example of the incidence of plague is in Calcutta. If there is any place which might be expected to suffer severely it is Calcutta and yet all last year only 200 deaths were recorded and the outbreak this spring still keeps within very moderate dimensions. There are signs now that it is even abating and at no time have there been reported as many deaths for a whole week as Bombay has suffered in one day. No satisfactory explanation has been given. The rat population does not seem nearly so numerous as in Bombay and elsewhere, but the type of the disease besides does not appear to be nearly so virulent. Whether the frequency of malaria has anything to do with it is not proven. The theory is very fascinating because there is evidence to show that the toxin of plague is inimical to malarial developments. Plague, however, has developed to a sufficient degree during this second outbreak to suggest that if the antagonism does exist the more virulent and fatal disease of plague overcomes in time and by degrees the apparently protecting influence of malaria. The conditions of the basements of the majority of the dwellings seem to offer unfavourable harbours for a large rat population and it is therefore possible that the slow development and slow spread, as well as lessened virulence of the outbreak, may be associated with the absence of that extreme intensity which characterises the disease in the rat. In the district of Bengal also the plague does not seem to make much headway. A few places still continue to record cases but there is no serious outburst. In Nagpur city the improvement previously recorded continues and in Poona the expected development seems to hang fire. The cases are still numerous in the Kolar gold fields and labour troubles are much complained of.

At the instance of the Government of India new and stringent regulations regarding the inspection and disinfection of native passengers and crews leaving Calcutta are likely to be issued almost immediately by the Government of Bengal, which will bring the rules of the port more directly into line with the requirements of the Venice Convention and under these regulations the clothing and bedding of all deck passengers and native crews will have to be disinfected on shore within the limits of the port before embarkation on outgoing ships and steamers. It is proposed to have three or four disinfecting stations all within the limits of the port.

Fresh evidence of the value of inoculation is furnished by the results obtained at Broach. At the same time, as the people who were chiefly inoculated were Parsees and not a proportionate representation of the whole population, too much reliance cannot be placed on the published figures. Better evidence is furnished by the tailors of Broach who were living in a camp outside the town and here it seems very clear that those who were inoculated came off much better than those who refused to go through the operation. Amongst the 90 inoculated not a single case occurred while there were ten cases and six deaths among those who remained un inoculated (135).

With regard to the importation of "jigger" a resolution has been issued by the Bombay Government concerning measures to be taken to prevent the importation into India from British East Africa of the disease called by that name. The Surgeon General has recommended the following:—(a) Periodical inspection and careful treatment of all Indian coolies employed by Government in British East Africa or in other parts of the continent having direct communication with Indian ports. Special attention to be paid to time expired men for a month before their return to India. (b) Medical inspection of all persons leaving East African ports for India and prohibition of embarkation for India of those found on medical inspection to be suffering

use of glycine in renal calculus now reported an additional series of 85 cases. In 14 cases calculi were passed with relief to the symptoms, in 17 cases calculi were passed without improvement in the patient's general state, and in 54 cases there was no result from the treatment. Glycine did not dissolve the calculi, but by increasing the alkalinity of the mucous membrane of the uropoietic system it facilitated their discharge. Very pure glycine administered in large doses amounted to 130 grammes (four and a half ounces). Glycine had no injurious action on the kidneys—Professor VON JARSCHE remarked that large doses of glycine might produce alterations in the blood and bring about nephritis.

Among the other communications which were read mention may be made of papers by Dr WINKLER and Dr JACOB on *Quadrac Insulinogen*, by Dr GORDON on the action of Digitalis in Heart Disease, by Dr LERTY-DONK and Dr ROSENGEN HAYS, by Dr ALLEN and Dr PEAVLER on the Section of the Gastro Duod, and by Dr BLUM on the Physiology of the Thyroid Gland.

Injurious action on the kidneys—Professor VON JARSCHE remarked that large doses of glycine might produce alterations in the blood and bring about nephritis.

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday A New Departure

The seventh annual meeting in connection with the Hospital Saturday Fund was held on May 8th under the presidency of the Lord Mayor (Mr Alderman Beale). The chief business affecting the medical profession was the report of the Executive Committee appointed to consider the scheme suggested by the Lord Mayor (Mr Alderman Beale). The scheme suggested by the Lord Mayor (Mr Alderman Beale) was the report of the Executive Committee appointed to consider the scheme suggested by the Lord Mayor (Mr Alderman Beale).

Mr Arthur Chamberlain's proposal as to the establishment of a consultative institution. The scheme suggested by the Lord Mayor (Mr Alderman Beale) was the report of the Executive Committee appointed to consider the scheme suggested by the Lord Mayor (Mr Alderman Beale).

Proposed Crematorium
An effort is being made to establish a crematorium in Birmingham. Several meetings have been held in the local press. The General Committee has reported that in its opinion the Manchester building, and management are superior to those of Glasgow, but the furnace in the latter place is inconvenient distance of the city and to erect handsome and well arranged buildings, and that it would be best carried out by the formation of a small limited liability company with a capital of £10,000 with the understanding that the object would be to further a much needed reform rather than to make a pecuniary profit. The medical officer of health, Dr Hill, was called upon to bless the project and point out its advantages and the co-operation of the clergy was invited. Thus far there seems to be a probability of the undertaking being pursued to a definite conclusion at no distant date.

Reception to Nurses

By the kindness of the Lord Mayor and Lady Mayores an enjoyable evening was spent at the Council House on April

f gastric ulcer, cholelithiasis, and uncontrollable vomiting here was a possibility that relief might be obtained by artificial means. Operations were performed six times for the symptoms, in 17 cases calculi were passed without improvement in the patient's general state, and in 54 cases there was no result from the treatment. Glycine did not dissolve the calculi, but by increasing the alkalinity of the mucous membrane of the uropoietic system it facilitated their discharge. Very pure glycine administered in large doses amounted to 130 grammes (four and a half ounces). Glycine had no injurious action on the kidneys—Professor VON JARSCHE remarked that large doses of glycine might produce alterations in the blood and bring about nephritis.

Diagnosis of Gastric Ulcer

Dr. SCHUTZ (Wiesbaden) said that certain symptoms produced by some diseases of the colon, such as colitis, or even certain symptoms produced by constipation, were very similar to those of gastric ulcer. The occurrence of hæmorrhage served to confirm the diagnosis of ulcer, but in the absence of hæmorrhage it was possible that the phenomena presented might be accounted for by the conditions above mentioned. The pain in diseases of the colon and of the stomach was felt as a rule in the pit of the stomach. Pain in the stomach might sometimes be removed by free emptying of the colon. In colitis the quantity of free hydrochloric acid was diminished. By attention to these points patients with doubtful symptoms might sometimes be spared the inconvenience of an unnecessary treatment for gastric ulcer.

Tuberculosis of the Larynx

Dr. STURMANN (Berlin) expressed the opinion that laryngeal tuberculosis was not a local disease. With few exceptions it did not occur primarily and was seldom confined to the larynx. Surgical treatment as recommended by the specialists was therefore contra indicated in the majority of cases, for it was likely to diffuse and aggravate the tuberculous condition. Surgical treatment in this disease went no further than the relief of symptoms. Hygiene and diet ought to be attended to as in pulmonary tuberculosis. Rational prophylactic measures were very valuable, laryngeal tuberculosis was as a rule preceded by simple laryngitis, which must be energetically combated. Plenty of nourishing food was essential and a saturated diet had been found to be treated like those of the joints by rest, ice, hydrotherapy, or a mild antiseptic. Although could be highly recommended for the relief of the pain. Operations including cauterisation, ought to be performed only on robust persons free from lung disease—Dr. SCHMIDT (Frankfurt) opposed those views, saying that prophylaxis was generally impracticable. The prognosis was not so bad as was alleged by Dr. Sturmann, for in the Berliners sanatorium 37 per cent. of the cases recovered. Tuberculous ulcers of the larynx were to be scraped in the manner with those occurring in other parts of the body and they frequently healed up afterwards.

Elimination of Fat by the Skin

Dr. LEBRUSCHKE (Altenberg) said that the elimination of fat through the skin varied according to the person's age and constitution, being most abundant in the young, but that sex had no influence. He had observed that in stout persons more fatty matter was way through the skin than in those who were lean and he was therefore of opinion that certain relations existed between the formation of fat in the organism and its elimination by the skin. On an average 150 cubic centimetres (about three and a half ounces) were given off in a week, in exceptional cases, however, the amount might be more than 300 cubic centimetres (more than 10 ounces). The quantity was not augmented by muscular exertion and was not affected by atropin, thyroïd or pilocarpin. The nature of the food, however, had a very obvious influence, for when it contained much fat the elimination was increased. In acute vulgaris the subcutaneous secretion was augmented, in enteric fever cutaneous, and carcinoma it was diminished.

Glycerine in Renal Calculus

Dr. HENRIK (Carlsbad) who has already written on the

section The first question is the protection at their source of water courses, and the administrative measures necessary for the prevention of river pollution, Dr Thubault (Lille), Dr Lannay, and Dr Miquel, reporters Second question household refuse, its collection, transport, and final treatment, sanitary measures to be enforced in houses and towns, M Hudelo and M Petsche, reporters Third question the domestic sanitation of houses, draining into public sewers, and the necessary by laws, M Lacau and M Masson, reporters Fourth question the necessary laws for the disposition, ventilation, and decoration of the interior of dwelling-houses, M Grouvelle and M Pucey, reporters Fifth question the atmosphere of towns, noxious gases, smoke prevention, &c, Dr Armand Gautier, reporter Sixth question urban by laws regulating the construction, preservation, &c, of thoroughfares, M Emile Trélat, reporter Seventh question the sanitation of seaport towns, M Rebuffel (Marseilles), reporter

The Fourth Section (Dr Th Roussel, president, and Dr Deschamp, secretary) deals with the Hygiene of Childhood and Individual Hygiene On the former question Dr Budin, Dr Napias, and Dr Dubrisay are the reporters On physical exercise and cycling Dr Lucas Championnière is the reporter Then there are to be reports on the medical inspection of schools, on dealing with cases of infectious fever in schools, &c, and on the progress of cremation

The Fifth Section deals with Professional and Industrial Hygiene and with Unwholesome Dwellings The president of the committee is M Siegfried and M de Palligny is the secretary The first question is the prophylaxis of phosphorus necrosis, the actual state of the legislation in various countries on this question, its results, and the further reforms needed, M Courtois Suffit is the reporter Second question prophylaxis in regard to illness and accidents caused through the employment of poisonous substances—mercury, arsenic, lead, copper, &c—in various processes of manufacture, the legislation of different countries on this subject, the results attained and the reforms which are desirable, Dr Layet (Bordeaux) reporter Third question unwholesome dwellings, existing legislation of different countries in relation thereto, its results, and the further laws needed, M Challamel, M de Palligny, and M Weber, reporters Fourth question legislative limitation of the hours of labour, M Vaillant, reporter

The Sixth Section deals with Military, Naval, and Colonial Hygiene Dr L Colin is the president and Dr Ferrier is the secretary of this section The first question relates to field and temporary hospitals, Dr Richard and Dr Ferrier, reporters The second question is the ventilation of ships, Dr Michel, reporter The third question is on the sanitary precautions necessary in hot climates, Dr Reynaud, Dr Bonvalot, Dr Henry, and Dr Thierry, reporters The fourth question is concerned with the ensuring of a pure water supply in the colonies, Dr Bonnafy reporter

The Seventh Section is devoted to General International Sanitary Measures The president is Dr Proust and the secretary is Dr Mosny Special stress is laid on the first question, comprising the study of the different measures taken and the results actually attained to prevent the spread of tuberculosis in families and communities, Dr Landouzy and Dr Mosny are the reporters Second question the compulsory notification of contagious diseases and the consequent necessity of isolation and disinfection, with the results attained in various countries, reporters, Dr Vallin and Dr A J Martin Third question the various measures enforced for the prevention of syphilis, reporters, Dr Fournier and Dr Bourges Fourth question international measures against yellow fever, reporter, Dr Proust

The Eighth Section or Demographical Division has M Levasseur for president and M J Bertillon for secretary The first question relates to statistics on the consumption of alcohol—what amount of absolute alcohol has been drunk during the last 50 years, what measures have been taken against the abuse of alcohol, and what effect have such measures had on the consumption of alcohol, M Blanchetville, reporter Second question the housing of the population—according to existing statistics and census returns what is the distribution of the population in regard to the number of inhabited rooms (a room should be defined as a place large enough to hold a bed—namely, measuring at least two metres by one and a half metres), M Fontaine, reporter Third question the movements of the population in regard to their financial means, M J Bertillon, reporter Fourth question the classification of the physique of conscripts,

students, and other adults during the last 20 years, M Longuet, reporter

Early efforts have been made so as to render the discussion on Tuberculosis especially instructive and far reaching Two circulars, in which a great number of questions have been inscribed with blank spaces for the answers, have been prepared and will shortly be despatched to all known authorities in different countries The first deals with general and international hygiene for the prevention of tuberculosis The first questions asked relate to the statistics of tuberculosis during the 10 years from 1888 to 1898, whether during that period tuberculosis has increased or decreased, in what regions was it especially prevalent—among the general population or in hospitals, schools, large offices, railway stations, banks, hotels, barracks, ships, artisans' dwellings, &c Secondly, what measures have been taken to prevent the spread of this disease either by the State, local governments, private individuals or enterprises, &c Thirdly, what have been the results of such measures The second circular deals exclusively with the army and the navy Statistics are requested for the same period, and the details as to whether any particular regiments or services are especially affected For instance, do the cavalry or the infantry, the able bodied seamen or the marines, suffer most from tuberculosis? Again, are recruits or veterans more subject to this disease? Then there are questions in regard to the preventive measures taken, especially in dealing with recruits and their medical examination before they enter the ranks Of course, there are also many questions in respect to the barracks, infirmaries, &c These questions have been very carefully drawn up and if they are as carefully answered a great mass of very useful information will be collected The reporters are Dr Landouzy and Dr Mosny They will group together and analyse the replies and will be able to lay before the Congress a very instructive report, particularly as they are taking time by the forelock and are collecting their information in a systematic manner

Dr A J Martin, who is so well known in connexion with these congresses, is the general secretary of the International Congress of Hygiene and all communications relating to the Congress should be addressed to him at No 3 rue Gay-Lussac, Paris Dr Martin assures me that every effort will be made to print at least the more important reports in all the three official languages and that they will be forwarded to the members of the Congress several weeks before the Congress meets Such reports as cannot be translated will contain at least a summary in the three languages Thus the members will know well in advance what are the principal points raised and what has to be discussed This is by far the best way to ensure order in the debates and to elicit useful information The present description of the subjects to be discussed, being published a year and three months before the actual meeting of the Congress, will serve to give the British members ample time to prepare It will be their own fault therefore if they fail to make useful communications and to distinguish themselves on this auspicious occasion At Madrid it was decided that a British committee should be formed so as to group together the British delegation and to facilitate the journey of the members to Paris It will soon be time for this committee to meet and to get into working order To ensure success it is necessary not to leave such matters to the last moment Our French colleagues in any case are well to the fore Let us follow this good example

Paris, May 7th

THE CONGRESS OF INTERNAL MEDICINE AT CARLSBAD

(FROM OUR BERLIN CORRESPONDENT)

(Concluded from p 1257)

Surgical Operations for Non-malignant Diseases of the Stomach

DR PETERSEN (Heidelberg) gave an account of 77 operations on the stomach performed in the Heidelberg University Hospital Surgical treatment, he said, was always indicated in cases of pyloric stenosis with mechanical insufficiency, of the 57 patients operated on for this condition 40 had suffered from gastric ulcer, eight from cholelithiasis and four from cicatrices produced by corrosive substances In some cases

25th by a large number of nurses. Invitations were issued to some 650 nurses, and the members of the City Council, the chairman and secretaries of the various hospitals, and a few private friends were asked to meet them. The staffs of 13 hospitals, six district nursing societies, and a number of nursing institutions and training homes were recipients of invitations. Music, visiting the Art Gallery, and other entertainments with appropriate refreshments, constituted a most pleasant evening, during which the Lady Mayoress emphasised the interest which she has always so prominently taken in the welfare of nurses and nursing in all its branches.

The Royal Society

The friends of Professor B O A Windle, the dean of the Medical Faculty at Mason University College, are very pleased to see his name among the list of nominations for the Fellowship of the Royal Society.

May 9th.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Care of Pauper Children

THE Oldham guardians decided on May 3rd to take control of the pauper children who had been reared in the workhouse. This course has been taken owing to the fact that it is a common thing for parents who have deserted their children to claim them when they reach the age of 16 or 18 years. The guardians will no doubt be better able to guide them to a decent course in life than such parents. Mr Jenner Fust, the Local Government Board inspector, remarked that the proposal was a very sensible one.

Methylated Spirit as Whisky

It is seldom, one would think, that methylated spirit is sold for whisky, but the other week a man described as a hawker was fined at Bolton £51 and costs or six months' hard labour for so doing. He must have found it profitable as he had been fined on former occasions £51 and £24, and on three occasions £25 and costs, and had served various long terms of imprisonment. It bespeaks an uncultivated taste if he succeeded in palming such stuff on his customers for "fine Scotch," or an insatiable craving for alcohol of any sort or description. One would like to know if there are confirmed methylated spirit drinkers at Bolton or if the effects of taking it have come under the notice of any of the medical men.

Poisoning by Ammonia at Stockport

An inquest was held on April 28th at Stockport on the body of a lady, feeble from chronic bronchitis, who got some ammonia to remove stains from a carpet and accidentally inhaled it. Her husband, one of the oldest members of the corporation, said that he was certain that she drank none. The verdict was "Death from bronchitis accelerated by accidental inhalation of ammonia." It is stated that there have been a number of deaths recently in Stockport from taking ammonia. It is difficult to imagine anything more horrible than the swallowing of ammonia or carbolic acid, and yet the latter, in addition to the accidental deaths caused by it, is among the lower classes one of the favourite instruments of suicide. A death from ammonia poisoning took place about a month ago at Guide Bridge. A man sent to a shop for a pennyworth of sweet nitre, but ammonia was given by mistake. The shopkeeper said that "she kept a general shop and sold sweet nitre, ammonia, and many other articles of a similar nature" and that she understood the boy to say ammonia. At the request of the jury she was censured severely and told that they did not believe her evidence. It is difficult to ensure care and accuracy in the seller and more difficult to save the buyer of such things from a "general shop" against his own stupidity and carelessness.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

University College, Liverpool. Court of Governors, a New Fellowship in the Medical Faculty

At a meeting of the court of governors held in the senate room of the College on May 6th Principal Glazebrook

made a statement dealing with the work done since the last meeting of the court. Referring to the number of medical students he said that in spite of a slight decrease in the total number there had been a very considerable increase in the number of new students—namely, 88 against 71 in the previous term. As to the work of the students it was difficult to say very much because only a few of the final examinations had been held. Those who knew the work were thoroughly satisfied with the success of the final examinations for the degree of M.D. in March last and there was every prospect of a high standard being attained in the other examinations. In regard to the changes in the professorial staff Dr Briggs had been appointed professor of midwifery and gynecology in the room of the late Dr John Wallace, while Dr Grimsdale had been appointed clinical lecturer on gynecology. Speaking of the position of the various building funds Principal Glazebrook said that plans had been prepared for the extension of the medical school, which would probably cost about £20,000, so that between £5000 and £7000 would still be required before the work could be completed. In regard to the new laboratory in the physics department Mr Alfred Booth had promised £2500 on condition that £7500 additional should be raised. Considerable amounts had already been received towards that object and they hoped before long to be able to announce the receipt of the £25,000 required for the work. At a meeting of the Medical Faculty held on May 5th it was announced that Dr William Alexander, surgeon to the Royal Southern Hospital, had generously offered a fellowship or studentship in pathological science of the value of £100 a year for five years at least. Mr Edward Phillips, the dental surgeon to the Liverpool Royal Infirmary, had also offered a prize of the value of 10 guineas for students in dental science for a term of five years at least.

Pathological Diagnosis Society

The second annual report of the society states that the number of subscribers is slightly less than last year—viz., 140 as against 163. The work done, on the contrary, has increased, nearly 600 reports having been sent out. In the Thompson Yates Laboratories a special room had been devoted to the work with a laboratory assistant, so that in all urgent cases, as in the bacteriological diagnosis of diphtheria and typhoid fever, a reply can be given within 24 hours. Two hospitals—viz., the Liverpool Infirmary for Children and the Royal Albert Edward Infirmary, Wigan—have joined the society during the past year.

The Liverpool Chamber of Commerce and the Vaccination Act (1898)

At the monthly meeting of the Chamber of Commerce, held on April 28th, the secretary reported that a letter had been received from the Town Clerk asking, on behalf of the Health Committee of the City Council, for the cooperation of the Chamber in an effort which they were making to secure for Liverpool exception as regards domiciliary visits under the Vaccination Act, 1898. The new procedure was, in the opinion of the Health Committee not suited to the circumstances of Liverpool. They therefore wished the Government to consider the case of Liverpool exceptionally and to restore the vaccination stations. It was unanimously agreed by the Chamber that the support asked for by the City Council should be granted.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

University of Edinburgh

ON May 2nd the classes for the summer session were opened in the University of Edinburgh. The introductory lecture of the newly instituted course in tropical medicine was delivered by Dr Andrew Davidson who has been recently appointed by the University Court as lecturer on that subject. Those present were for the most part graduates and senior students who intended to enter the services. The lecturer spoke of the importance of this subject, the objects of the course, and the part played by predisposition in determining infection and its influence on the type and severity of the disease. The University of Edinburgh sent as large a proportion of its graduates to the tropics as any other medical school in the kingdom, and it had now realised

is duty to them in the matter of providing instruction in the diseases with which they would have to contend in their work in tropical countries

General Council of the University of Edinburgh

The statutory half yearly meeting of the General Council of the University of Edinburgh was held on May 3rd in the Celtic class room of the University. In the report of the Finance Committee the committee referred to the Universities Act of 1889 which gave the University Court the power to administer and manage the whole revenue and property of the University, the intention of this arrangement being to relieve the Senatus of all financial administration and thereby to enable the professors to devote all their time to educational work. Referring to the matter of financial administration he explained that the committee in no way blamed the Senatus but that they considered it unfortunate that the donors should have so little considered the Universities Act of 1889 as to thrust this work on the Senatus by the terms of their bequests. The Finance Committee regretted to have to report that for the first time since 1889 this method of administration had in part been broken through the Senatus having entered on the management of two bequests which had recently been made in favour of the Senatus. This departure was an unfortunate as setting up a dual financial administration in the University. The report went on to state that the appeal which had been made for funds to provide a building for the newly founded chair of public health and the cataloguing of the library had been magnanimously responded to since 1889 there had been a large increase in the appointments of university lecturers and assistants. The increases in lecturers was, however less than it would be if funds were available. In many cases the court had been forced to select men as lecturers who were also assistants to professors. This had happened in 21 cases. The capital fund in 1897-98 amounted to £687,133, as compared with £676,081 in 1896-97. The total number of matriculated students in 1897-98 was 2780. In moving the adoption of the report Mr Buchan, referring to the question of lecturers, pointed out how much more satisfactory it would be had the University funds to enable them so to remunerate the University lecturers as to make those gentlemen independent and to enable them to devote all their time to work in the subject on which they lectured. If a man held the two posts of lecturer and assistant to a professor and derived 60 per cent of his income from the assistantship he naturally was obliged to give most of his time to the work which fell to him as assistant.

At the monthly meeting of the Faculty of Physicians and Surgeons, Glasgow, held on May 1st, Dr John Dougal of St Mungo's College was appointed examiner in medicine and materia medica for the dental diploma.

IRELAND

(FROM OUR OWN CORRESPONDENTS)

GURMANS & DEMPSEY

DR LUTHERS has recently been appointed chief medical officer to the immense establishment known as Guinness's Brewery. It will be remembered that Thel Royal High Institution with a visit

Royal College of Surgeons in Ireland

The Court of Examiners for the ensuing year was chosen by election on May 2nd. The most important changes were in the examiners in surgery, Mr Henry Gray Croly and Dr P Conway Dwyer having been selected to examine for Fellowship and Letters Testimonial in that subject.

Royal College of Physicians of Ireland

At a meeting of the President and Fellows of the Royal College of Physicians of Ireland held on May 5th the following were admitted Fellows—James Byrne Coleman and Francis Charles Martley. Dr Martley who is a graduate of Cambridge University recently passed with honours the examination for the degree in State Medicine.

Meath Hospital, Dublin

The annual meeting of the Friends and supporters of the Meath Hospital and County Dublin Infirmary was held on

A sub-committee appointed by the Joint Town Improvement and Public Health Committee of Belfast have visited various towns in England and submitted a report to the corporation upon the bacteriological treatment of sewage. They recommended that a portion of the sewage at the Belfast outfalls should be experimented on with the least possible delay in the hope that a way may be found for the disposal of this system on a large scale. They propose that two beds should be constructed at a cost of £1000 at Sperrinham and Greenacree. The surveyor of Belfast is to prepare a scheme for dealing bacteriologically with the sewage of these two localities.

The Ulster Medical Society

At the monthly meeting of this society held on May 4th Dr Dempsey read a paper on Ferriaritis with illustrative Cases, one of which was of special interest inasmuch as he had ascribed the pericardial sac with success. In the subsequent discussion Dr Caldwell, Dr McCaw, and Dr J A Lindsay took part. Dr Dorman read notes on a case of Gastric Tetany and notes on a case of Acute Circum scribed Edema. Dr Morrow, Dr Caldwell, Dr Dempsey, Dr McCaw, and Professor Byers made remarks on the cases.

The Belfast Board of Guardians and Consultants' Fees

It seems that the Belfast Board of Guardians have suggested to the Local Government Board to arrange that in future if any of their dispensary medical officers should need the assistance of a consultant the fee is to be one guinea. Such cases are usually obstetric and operative and although the minimum fee has been two guineas. The Ulster Medical Society at their meeting on May 4th passed a resolution protesting against this extraordinary proposal and it is to be sent to the Local Government Board.

The Belfast Water Bill

This Bill, the object of which is to confer power on the Belfast Water Commissioners to extend their district of supply, to make further works, and to purchase a large portion of their catchment areas so as to prevent the risk of pollution of the city water supply, came before the House of Commons on May 3rd and 4th. At the present time the Commissioners are pushing on with their scheme to bring a pure water supply from the Altonne Mountains and in about two years a small supply will be available from this district which is 40 miles from the city of Belfast. There are now two catchment areas (one at Carrickfergus and the other at Boneyford) from which the present water supply is obtained. Within these catchment areas there are farms and hence the risk of contamination of the water supply.

both directly from the farms as well as indirectly by manure brought from Belfast and spread over the fields there. During the past two years there has been a severe outbreak of typhoid fever in Belfast and last year the death rate from that disease rose to 2.9 per 1000. Experts were asked by the Water Commissioners and the city corporation to look into the cause of the epidemic and although they differed on some points they were both of opinion that it might have been introduced by the water supply, while admitting the insanitary condition of the low lying drains of Belfast. Further, it was distinctly proved that there were cases of typhoid fever on the catchment areas themselves. Under these circumstances the Belfast Water Commissioners decided to purchase the lower part of the catchment area so as to preserve their reservoirs from pollution, this meant buying up 4186 acres in which there were 188 dwelling houses and three schools with a population of 1188 persons. The only opposition offered was from the farmers and occupiers of land in the Carrickfergus district. After hearing evidence (expert, sanitary, and medical) the Committee decided that the preamble of the Bill was proved, but that a clause should be added securing to the persons whose holdings are required by the Commissioners 18 months' notice before they are dispossessed of their land under the powers of the Bill. This concession has, however, been since abandoned, the tenants being advised to give up their holdings as soon as possible and to treat without delay for compensation with the Water Commissioners.

Presentation to Mr R P Byrne

A presentation was made to Mr R P Byrne on May 6th by the students of the North Infirmary, Cork, on the occasion of his severing his connexion with the hospital as house surgeon. The presentation consisted of a surgical dressing-case, a midwifery bag, and a hypodermic case. The chair was occupied by Mr Denis Donovan, physician to the hospital, and Mr J P Higgins, M.A., read the address which referred to the cordial relations which had always subsisted between Mr Byrne and the students. The chairman and Dr N J Hobart, senior surgeon to the hospital, also spoke in high terms of the manner in which Mr Byrne had discharged his duties, and congratulated him on his recent appointment as medical officer of one of the city dispensaries. Mr Byrne suitably replied. Some days previously the sisters of charity in charge of the hospital presented him with a tea service and he was the recipient of a solid silver cigarette case and an umbrella from the nursing staff.

Dr Power has been appointed house surgeon to the South Infirmary, Cork.

May 10th.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Treatment of Appendicitis

THE discussion upon the treatment of appendicitis which has been going on at the Society of Surgery during the past three months has just come to an end, possibly somewhat to the relief of the medical world. Every surgeon successively laid before the meeting his views upon the origin and course of appendicitis, together with that most important point, the conditions which in his opinion made it necessary to interfere by operation or the reverse. At the same time the physicians discussed the matter at their own particular society—namely, the Hospitals Medical Society—and the question was also argued by both physicians and surgeons at the Academy. One rather remarkable result was arrived at by the physicians, with Professor Dieulafoy at their head, insisted that appendicitis ought to be treated at the earliest possible moment by operation, while the surgeons, led by Professor Tillaux, considered that in many cases a waiting policy and medical treatment were quite sufficient and that this was especially the case in a first attack. Professor Dieulafoy says that there is no such thing as medical treatment of appendicitis. Many of the younger surgeons, however, reported the opinion of Professor Dieulafoy. (FROM OUR OWN CORRESPONDENT) appear to have won the day in this long Society of Surgery has not yet defined its position on the matter, but at the University College, Liverpool, a communication was received from the Faculty of Medicine. Fellowship in the Faculty of Medicine reflects the general opinion of the college. (1) there is no room of the College on the subject of appendicitis, (2) in acute cases operate

as soon as possible after the diagnosis is made, (3) in doubtful cases it is better to operate, (4) in subacute cases it is possible to wait and operate *à froid*—i.e., between the attacks—but most of the members of the society prefer to operate at once, (5) suppurative appendicular peritonitis demands instant operation, (6) in slight cases it is less risky to operate at once than to wait and operate *à froid* and diagnosis especially in the early stages is anything but easy, and (7) the steps of the operation must vary according to the needs of each particular case, resection of the appendix should be practised in every case where the search for it does not involve much injury to the tissues. The possibility of a ventral hernia (*éventration*) after the operation *à chaud*—i.e., in the acute stage—is not a reason for putting off operation, for the risk of this occurring is less than the risks from waiting. M Poinier added that if any definite rules for the conduct of a case of appendicitis had been arrived at the credit was due to Professor Dieulafoy.

The International Congress of the Medical Press

The Organising Committee of the International Congress of the Medical Press which will be held in Paris during the year 1900 met for the first time in the Exhibition Buildings on April 20th and proceeded to elect its officers as follows—President, M Cornil, Professor at the Faculty, Member of the Academy of Medicine and Senator. Vice-Presidents, M Lucas-Championnière, surgeon to the hospitals, Member of the Academy, editor of the *Journal de Médecine et de Chirurgie Pratiques*, and Dr V Laborde, in charge of the physiological work at the Faculty of Medicine, Member of the Academy and editor of *La Tribune Médicale*. Secretary, Dr Blondel, in charge of the laboratory of the Charité Hospital and editor of the *Revue de Thérapeutique*.

Obituary

Dr Le Sourd, editor of the *Gazette des Hôpitaux*, which post he had held for 30 years, has recently died, aged 75 years.

Notes on News

The old Obstetrical and Gynaecological Society of Paris has just been broken up. A purely obstetrical society was formed some months ago out of the members of the old society under the presidency of Professor Budin. A purely gynaecological society is also in process of formation. Besides these there was founded some two months ago a society of obstetrics, gynaecology, and pediatrics under the presidency of Professor Pinard. There is also a society which deals with nothing but pediatrics, and a second one is in process of formation comprising members who were unwilling to belong to the other one. The influenza epidemic is almost at an end. Only 31 deaths were attributed to this cause during the past week. On the other hand typhoid fever seems to be increasing and 21 deaths occurred from this disease last week, the mean number at this time of the year being six. The new cases reported to the Prefecture of Police numbered 108. The hospital ship *St Paul* which was launched last year to accompany the fishing fleet (*pêcheurs d'Islande*) was wrecked 15 days ago. This is the second hospital ship sent out by the Société des Œuvres de Mer. The first ship, the *St Pierre*, was wrecked last year. The society has now decided to build no more sailing hospital ships but only steamers. Dr Duclaux, director of the Pasteur Institute, and Dr Grimaux, agrégé Professor of Chemistry at the Faculty of Medicine, have been prosecuted by the Correctional Tribunal as being members of the League of the Rights of Man which was founded in favour of Dreyfus and have, as have many members of previous leagues, been fined, time being given for payment.

May 9th

BERLIN

(FROM OUR OWN CORRESPONDENT)

Intemperance in Relation to Climate and Season

AT a recent meeting of the Berlin Society of Public Health Dr Baer, chief medical officer of health to the Ploetzensee prison, read a paper on the Relations between Alcoholism and the Time of Year. Meteorological conditions, he said, had a marked influence on the prevalence of alcoholism. It was an established fact that more spirits were consumed in winter than in summer and that the use of alcohol increased as one proceeded from the equator to the poles. On this account it might perhaps be supposed that pathological conditions due to alcoholism were most prevalent during the

cold season of the year, but this inference would not be in accordance with the facts, for it has been proved statistically that diseases attributable to intemperance is most common in the summer. It is also known that the incidence of alcoholic injuries is much more injurious in the tropics than in mid-European climates, the degeneration or certain native races in the tropics being due to the ravages of alcoholism. Statistical returns from Stockholm, St Petersburg, Munich, and Paris have shown that delirium tremens is at its maximum of frequency in July and August and at its minimum in February and March. The same fact was recognised in Berlin, where from 1679 to 1698 not less than 15,937 cases of delirium tremens were treated in eight of the larger hospitals. Some writers were of opinion that the prevalence of delirium tremens in the summer months was due principally to the better wages earned in summer by working people who therefore had at that time more money to spend in drink. Dr Baer, however, argued that the price and the entire organism is less resistant to alcohol in summer than in winter, a fact which helps to explain why mental disorders, and acts of violence are most frequent in summer. There is of course an increased consumption of fluid in summer time, and it is greatly to be desired that the demand should be met by the introduction of a refreshing and palatable substitute for alcoholic liquor. Dr Baer recommended a mixture of cold tea and lemon juice.

Treatment of Hydophobia

At a meeting of the above society Professor Pfeiffer made a statement relative to the treatment of hydrophobia as conducted in the Hospital for Infectious Diseases. He said that rabies was not so rare in Germany as it was generally believed to be. In the interior of the empire it has nearly disappeared in consequence of the strict enforcement of the muzzling order, but in the eastern districts, especially in those near to the Austrian and Russian frontiers, a considerable number of persons have been bitten by mad dogs. Persons have also been bitten by other animals which had previously been bitten by mad dogs. One or two months generally elapse between the bite and the first appearance of the symptoms, so that ample time is available for the giving of preventive injections. The earlier the injection the better are the results. When the virus has reached the brain and the medulla a fatal issue is certain. The method of injection adopted in Berlin is similar to that of the Pasteur Institute at Paris. The injections have hitherto been successful in every instance. From July, when the rabies department was opened, to the end of 1898 there were 137 patients treated, 91 men and 43 women. In 92 cases the wounds were infected on the hands and the head, where the bites are more dangerous than on parts protected by clothing. In 107 cases the heads of the animals by which the patients were bitten were sent to the institution and on being there submitted to examination it was found that 95 of the animals showed evidence of hydrophobia.

Quintuple Birth

A case of quadrupel birth is reported by Dr Bernheim of Philadelphia, U.S.A., in the *Deutsche Medizinische Wochenschrift*. This rare event happened in Mayfield Kentucky, U.S.A. The mother was delivered within an hour, the children being born one after the other at intervals of 10 minutes. They appeared quite healthy, there being no obvious cause for their deaths. They died, however, the first in four days, the second in 11 days, the third and fourth in 23 days and the fifth in 14 days. There were also complete placental conjoined to form one large mass with five umbilical cords. The mother was confined within the eight month pregnancy and made a slow recovery. According to Professor Schroeder's text-book twins occur once in 69 births, triplets once in 7910 births and quadruplets once in 371,126 births.

ROLE

(FROM OUR OWN CORRESPONDENT)

The Approaching International Congress on Tuberculosis at Berlin
Is no European country are the proceedings of this great meeting—one of the most important of the current year.

UNIVERSITY OF DURHAM—At the Convocation held on April 29th the following degrees and diplomas were conferred—

The Latest Contribution to the Therapeutics of Tuberculosis
At Palermo, Dr Vincenzo Cerrullo, professor of pharmacology in the University, has just communicated to the Accademia delle Scienze, of which he is president, an elaborate report of 26 cases of carefully diagnosed pulmonary tuberculosis treated by him in the Gangara Hospital for Consumption. Inhalations of "formalina," entering largely into a medicated vapour to which he has given the name of "gazolo," were tried for the first time on Jan 15th on the 26 patients referred to. In 19 of them the normal temperature, coincidentally with the cessation of the pyrexia the cough and the characteristic rales ceased and from the sputum the tubercle bacilli had disappeared. A final consultation with his colleagues 10 of the patients were pronounced cured and nine progressing towards recovery, of the other seven three were distinctly improved, two were stationary, and two died. These latter, when admitted to hospital, were found to be "in conditio gravissima." On concluding his report Professor Cerrullo introduced the 10 *gazole* to the Accademia. All of them looked healthy, "con un aspetto bonito," and on examination the marks of tuberculosis have so far satisfied treatment on a scale sufficient to justify a sound clinical induction, for which with commendable manageance a Republican bank (I may give his name, Signor Florio) has placed at his service an ample sanatorium equipped up to date, and has also founded "Un Istituto Cerrullo," on the model of the Pasteur Institute in Paris, the whole at a cost of 5,000,000 lire (2200,000).

UNIVERSITY OF CAMBRIDGE.—At the examination for the degree of M.C., Easter Term, the following candidate was successful—

J B Hall, M.A. Pembroke

At the third examination for medical and surgical degrees, Easter Term, the following candidates were successful—

Part I (Surgery and Midwifery).—R. G. Abercrombie, B.A. Caius, W. L. Ascherson, non-collegiate, F. A. Bainbridge, B.A., Trinity, H. P. Bradley, B.A., Caius, W. P. S. Branson, B.A., Trinity, W. R. Burdand, Jesus, J. P. Candler, B.A. Corpus Christi, A. E. Carver, M.A. and H. Edmondson, B.A., Clare, H. St. O. Elliott, Trinity, F. H. Ellis, B.A. Caius, F. O. Eve, B.A. Emmanuel, L. E. Gaskell, M.A. Christ, T. Gillespie, B.A. St. John's, D. G. Hall, B.A. Emmanuel, E. W. Hedley, B.A., King's, A. Killick, Downing, J. B. Linnell, B.A. H. Selwyn, T. Manners-Smith, Downing, H. N. Matthews, B.A., St. John's, W. H. Maxwell, Trinity, J. A. Nixon, B.A. Caius, S. V. Pearson, B.A. Emmanuel, A. O. Pearson, B.A. Sidney Sussex, J. H. Philbrick, B.A., Trinity, J. G. Taylor, B.A. King's, B. R. H. Truman, B.A., Trinity Hall, R. A. Walker, B.A. Clare, R. F. O. Ward, B.A. St. John's, D. P. Watson, B.A. Trinity, L. Wilkin, M.A. Pembroke, and W. M. Willoughby, B.A., Caius.

Part II (Medicine &c.).—H. F. Bassano, M.A. Trinity, G. Browne, M.A., Clare, H. N. Clarke, B.A., Trinity, S. E. Dore, B.A. St. John's, F. H. Ellis, B.A. Caius, J. H. Fryer, B.A., Christ, H. A. Galskell, M.A. Clare, J. R. Garwood, B.A. St. John's, K. R. Hay, B.A. Caius, J. B. Helm, B.A. Magdalene, R. J. Johnson Smith, M.A. St. John's, H. R. Hunt, B.A. Trinity, J. H. B. A. B. E. Fleming, B.A., and T. A. Mayo, B.A. Clare, F. Parker, B.A., Emmanuel, S. B. Reid, M.A., and F. A. Rose, M.A., St. John's, O. D. Somers, M.A. Pembroke, and F. G. Stacey, B.A. P. W. Sumner, B.A. and J. H. Tallent, St. John's.

Professor Sims Woodhead announces an inaugural lecture on the Relations of Pathology to Modern Medicine for May 23rd, at 2.30 P.M. The new regulations permitting Masters of Arts who are legally qualified surgeons to proceed to the degree of Master of Surgery have been approved by the Senate.

FOREIGN UNIVERSITY INTELLIGENCE.—**Strasbourg.** Dr Pfister has been recognised as *privat-docent* of Psychiatry—**Helsingfors.** The Chair of Physiology has been vacated by the resignation of Dr Conrad Hällsten—**Strasburg.** Dr Minkowski of Strasburg is to be offered the chair of Experimental Pathology, vacated by Dr Knoll, who goes to Vienna. The late Professor Neureuther has left a legacy of £10,000 to the new children's hospital—**St. Petersburg.** *Military Medico-Chirurgical Academy.* Dr Brusianin has been recognised as *privat-docent* of Hygiene and Dr Arliski as *privat-docent* of Surgery.

THE LATE DR D. A. MACCARTHY.—Dr Denis Augustus MacCarthy died at his residence, West Allington, Bridport, on May 1st. The deceased received his medical education at Dublin and Edinburgh. He qualified as M.R.O.S. and L.M. Edin in 1859, L.R.O.P. Edin in 1863, and took this M.R.O.S. Edin in 1882, graduating as M.D. Professor Dieulafoy. Before settling in Bridport Dr MacCarthy medical treatment of men in the Royal navy and was formerly surgeon, however, the Royal Marine Infirmary, Woolwich. Dieulafoy (FROM OUR) His death occurred in a very sudden manner, while he was sitting upon returning home he was sitting a patient in company with a Fellow of the Society in a few minutes. He has left a meeting of the Council, for whom much sympathy was expressed.

ROYAL ALBERT HOSPITAL, DEVONPORT.—A scheme has been prepared for extending and improving the Royal Albert Hospital, Devonport, at an estimated cost of £4000.

POPULATION OF BRISTOL.—The boundaries of the city of Bristol were again enlarged on Jan. 1st and the population is now estimated to amount to 320,911 persons at the middle of this year.

MEDICAL MAGISTRATES.—The names of Dr William Dobie, Mr John Patrick O'Connell, and Mr Edward Chaffers have been placed on the Commission of the Peace for the borough of Keighley.

LONG TENURE OF AN APPOINTMENT.—At the meeting of the Frome Board of Guardians held on May 2nd Mr Edmund Cockey, M.R.O.S. Eng., L.S.A., resigned the post of medical officer to the Frome Union Workhouse, an appointment which he had held for the past 55 years.

BRISTOL LUNATIC ASYLUM.—At the close of 1898 there were 773 patients in the asylum (375 males and 398 females). The extension of the asylum buildings is nearly completed and it is hoped that part will be ready for occupation early in the autumn.

FUNERAL OF MR G. J. HINNELL.—Mr George John Hinnell, M.R.O.S. Eng., L.S.A., of Bury St Edmunds, who died on April 22nd in his seventy fifth year, was laid to rest in the cemetery on May 2nd. The funeral was largely attended and in the town many blinds were drawn down and shutters closed.

MEDICAL DEFENCE UNION.—The following officers of the union have been re-appointed for the current year—President Dr W. S. A. Griffith, Treasurer Dr J. A. Masters, Honorary Secretary Dr Campbell Pope, General Secretary Dr A. G. Bateman. The following members have been elected Vice-Presidents of the Union and together with the executive, officers, and elected members form the Council of the Union: Mr Ganton Alderton, Mr O. A. Ballance, Mr Edgar Barnes, Dr James Barr, Mr James Blashopp, Mr A. H. Dodd, Dr Lovell Drage, Mr Samuel Evans, Dr W. A. Elliston, Dr J. S. Ferris, Mr E. Olmson Greenwood, Dr W. P. Herringham, Surgeon-General O. M. Jessop, Dr J. A. Masters, Dr Arthur Luff, Dr O. H. Milburn, Mr Marmaduke Sheild, Dr Frederick Nicholls, Dr Edward Nix, Dr Reginald Pratt, Dr F. A. Purcell, Mr Prior Purvis, Dr Walter Rigden, Dr R. Saundby, and Dr F. J. Wethered. Application forms, reports, and all information concerning the union can be obtained from the general secretary at the registered offices, 4, Trafalgar square, W.C.

FREEMASONRY.—*Rahere Lodge, No 2546.*—An ordinary meeting of the Rahere Lodge, No 2546, was held at the Restaurant Frascati on May 9th, W. Bro T. G. A. Burns, W.M. in the chair. Bros Tucker, Lewis, and Kennedy were admitted to the third degree, Bro Slack was admitted to the second degree, and Mr O. J. Heath was initiated into Freemasonry. Bro R. J. Reece, M.D., was elected W.M. for the ensuing year. Bro Godson was re-elected treasurer and Bro Madden was re-elected Tyler. It was decided that for the present no steps should be taken to found a R.A. Chapter in connexion with the Lodge. 40 members afterwards dined together and during the evening a wedding present, subscribed for by some members of the Lodge, was presented to W. Bro Burns.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—Dr Brasseur, *Chef de Service* in the Schaarbeek Hospital and a member of the staff of the *Press Médicale Belge*, at the age of 50 years—Dr Carlo Minati, formerly Professor of Midwifery and Gynecology in the University of Pisa—Dr Friedrich Heinrich Georg Burnbaum, for many years Director of the Cologne Midwives' Institute—Dr Jonquière, formerly Professor of Materia Medica in the University of Berne—Dr Henry Hoyer Wright, formerly Lecturer on Medical Therapeutics in the Toronto School of Medicine—Dr G. M. Herzogstein, formerly *privat-docent* of Medical Geography and Statistics in the Military Medico-Chirurgical Academy, and St. Petersburg—Dr Anastasio Zinnis, Professor of Children's Diseases in the University of Athens—Dr Ramon Félix Capdevila of Ferrer, formerly Professor of Clinical Medicine in the University of Madrid.

SUSSEX COUNTY HOSPITAL.—The opening of

the new building for the nurses will take place at the Sussex County Hospital on May 13th at 3.30 p.m. and the Sir Henry Harben, a former president of the hospital, will preside on the occasion.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.—

The Royal Highnesses the Duke and Duchess of York have consented to open the new building of the Royal London Ophthalmic Hospital on Monday, June 26th. This hospital was founded in 1804 and is generally known as Moorfields Eye Hospital. The new hospital is in City road, about one mile from the present site in Blomfield street. Provision is being made for 40 additional beds and for a much larger out-patient department. The hospital at present relieves over 400 cases a day.

ROYAL ALFRED WATER HOSPITAL, BATH.—The

annual meeting of this institution was held on May 1st under the presidency of General Janmanning. The report showed that during the past year 1250 patients had been admitted, the largest number in the history of the hospital, the average number in the hospital was 160 and the average stay of each was 40 days. The expenditure amounted to £5514 and exceeded the income by £142. The balance in hand was £567. Colonel Vaughan was elected president for the ensuing year.

LITERARY INTELLIGENCE.—Messrs Sampson

Low, Marston, and Co are issuing immediately a work which has already become known as a text book for teachers of physical training both in this country and America, though no English edition has hitherto been published. This is 'The Handbook of Medical Gymnastics' by Dr Anders Wide who is director of the Gymnastic Orthopaedic Institute at Stockholm. In addition to the ordinary Swedish drill exercises Dr Wide has written a section describing the treatment of numerous ailments of the muscles by means of appropriate exercises locally. There are nearly 100 illustrations in the book.

THE LATE DR J. EADIE.—Dr John Eadie died suddenly from syncope at his residence, West Coker, Teotih, on May 2nd. The deceased received his medical education at Queen's College, Belfast, and graduated as M.D. of the Royal University of Ireland in 1879, a year later he obtained the qualifications of L.R.C.S. and L.M.D. Dr Eadie, who had been in practice at West Coker for about 15 years, was medical officer and public vaccinator for the second district of the Teotih Union and was very popular in the district. Although only 43 years of age at the time of his death he had been in failing health for some months. He was left a widow and three children.

WINTERVALE ON THE COAST.—Cheap

tickets available for eight days will be issued to Brussels, May 18th to 20th inclusive and May 22nd, via Harwich and Antwerp. Passengers leaving London in the evening reach Brussels next morning after a night's rest on board the steamer. For visiting the Hague, Amsterdam, Utrecht, and other parts of Holland and the Rhine North and South Germany and Biele for Switzerland, special facilities are offered via the Great Eastern Railway Company's Royal Mail Harwich Hook of Holland route, through carriages being run to Amsterdam and Berlin, Cologne and Biele. Restaurant cars are run on the North and South German express trains. The General Steam Navigation Company's passenger steamers will leave Harwich on May 17th and 20th for Hamburg, returning on May 21st and 24th.

THE FRENCH HOSPITAL AND DISPENSARY.—The thirty-first annual dinner on behalf of the funds of this institution took place on May 6th at the Hotel Cecil in Paris, supported by the French Ambassador being in the chair, members of the corps diplomatique. The chairman said that he had had an opportunity of inspecting the hospital and had been greatly impressed by the ample provision for the care of the sick. He also spoke in terms of commendation of the convalescent home which had been recently opened at Bignon in connection with the hospital. The Italian Ambassador pointed out that the hospital received not only French sufferers but sufferers of all nationalities. He quoted the saying of a certain celebrated lady to the effect that the secret of not growing old was study, exercise, and the love of not growing old.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Scale for Shop Assistance

The Bill which passed the House of Commons for the provision of scales for shop assistants in Scotland was rejected on the second reading in the House of Lords. A Bill on the same lines with reference to England and Ireland has been introduced into the House of Commons by Sir John Lubbock, but after the fate of the Scottish Bill in the House of Lords it is not likely that it will be pressed.

THE HEALTH OF THE TROOPS IN AFRICA.
In the House of Lords on Thursday May 11th, Viscount Curzon raised the question of the sanitary condition of the military stations at Ladysmith in the colony of Natal and the health of the troops there. The Marquis of Lonsdowne, Secretary of State for War, in his reply, confessed that the health of the troops left much to be desired. He made inquiries into the matter but he could not find that the climate of Ladysmith, taking one part of the year with another, could be described as a bad climate, though there were undoubtedly seasons of the year when the weather was both hot and damp, and when that most terrible of scourges, enteric fever, became very prevalent amongst the troops. They had already done something to improve the sanitary conditions. They spent last year on the improvement of the huts a sum of about £3000. This year they were spending a further sum of about £15,000 upon the accommodation for the troops in Natal, a part of which would be spent at Ladysmith. He had received a very valuable report from the general officer commanding the troops in South Africa in which a number of practical and well-considered suggestions were made. One of these was to put the troops in camp during part of the year upon healthier ground, and a site had been selected which he believed was something like 5000 feet above the sea level. The general officer called attention to the surface draining and the desirability of improving the water-supply and hospital accommodation, and the use of other matters would receive the very careful attention of the War Office.

Mr Curzon has made it known that the inquiry conducted under the auspices of the Local Government Board.

Mr H. G. Wernher asked the President of the Local Government Board whether his attention had been called to the fact that, during the present small-pox epidemic in Hull, out of 25 cases admitted to the hospital, of whom three died, all the cases were of unconnected patients, and if the proportion of unconnected cases to the total number of cases in Hull was not the same as in the other districts. Mr Curzon replied that he had been acquainted with the fact that the proportion of unconnected cases to the total number of cases in Hull was not the same as in the other districts. He had no means of estimating the proportion of unconnected cases to the total number of cases in Hull, but during the last five years for which returns have been received some 50 per cent of these four days died. The remaining cases to be of a modified character and that none had died. The remaining cases to be of a modified character and that none had died.

HOUSE OF COMMONS.

THURSDAY MAY 11th.

Intelligence Questions

Mr Curzon has made it known that the inquiry conducted under the auspices of the Local Government Board.

of the children whose births were registered in the two Unions in which Hull is comprised and who survived when the returns were made were then unvaccinated.

Sir WILLIAM PRIESTLEY asked the President of the Local Government Board whether it was true that in Ipswich and other localities where previously there had been great opposition to vaccination the cases of vaccination had notably increased since the passing of the Act of last year, and that many parents who had been persuaded to apply for certificates of exemption had not presented them to the vaccinating officer but had subsequently had their children vaccinated.—Mr CHAPLIN: There is distinct evidence from reports that have been submitted to me that in a number of localities where previously there had been a great amount of default under the Vaccination Act, the number of vaccinations performed since the new Vaccination Act came into operation on Jan. 1st last has been in excess of that for any corresponding period in recent years. The case of Ipswich to which my hon. friend refers is one in point. There the average quarterly number of vaccinations performed by the public vaccinator during 1897 and 1898 was only 33, whereas in the first quarter of the present year the number vaccinated was 198. It is also true that in certain cases parents who on the passing of the Act of 1898 obtained certificates of exemption on the ground that they conscientiously believed that vaccination would be prejudicial to the health of their children have entirely on their own initiative procured the vaccination of those children.

Mr COOMBS asked the Home Secretary whether he would bring in a Bill to enable magistrates who have a conscientious objection to grant certificates of exemption from vaccination under Section 2 of the Vaccination Act, 1898, to decline to grant these certificates of conscientious objection.—Sir MATTHEW WHITE RIDLEY: No, sir.—The SECRETARY: I am doubtful whether this question ought to have been allowed to appear on the notice paper at all, for it is clearly of a satirical character.

The Mistakes of Dispensers.

Major RASCH asked the Vice-President of the Committee of Council on Education whether the attention of the Privy Council had been drawn to the evidence and verdict given at an inquest held at Heaton Norris on Jan. 9th 1899, from which it appeared that a mistake by a doctor's unqualified dispenser resulted in the patient's death and whether seeing that notwithstanding that the Pharmacy Act enacted that sellers of poisons must possess a qualification it was not illegal for doctors to employ any class of unqualified persons to dispense medicines, however dangerous or poisonous, the Government would take steps to ensure that medicines containing poisons should only be dispensed by those holding either a medical or pharmaceutical qualification.—Sir JOHN GOSCH: The answer to the first paragraph is yes and the Privy Council have been in communication with the General Medical Council on the subject. The Executive Committee of that body while admitting that occasional accidents may arise from the employment by qualified medical practitioners of careless or incompetent dispensers, consider such cases to be very rare and believe that the best protection is afforded to the public by the responsibility of the practitioner for the acts or defaults of the servants whom he employs. Instances of such mistakes are not confined to dispensers employed by medical practitioners.

The Law of Constructive Murder

In answer to a question on this subject, Sir MATTHEW WHITE RIDLEY said: I am of opinion that the law of constructive murder does require amendment, but it is a very difficult subject to deal with, and I cannot hold out any hope that the Government will be able this session to introduce a Bill or otherwise to afford adequate facilities for the treatment of this important question. I may add that I understand that the opinion of Her Majesty's Judges on the existing state of the law has been specially invited.

Aldershot Sewage Farm

Mr JEFFREYS asked the Financial Secretary to the War Office whether any and if so, what sale of milk now took place from the camp sewage farm at Aldershot, whether a committee of independent medical men had inspected the farm and the dairy and whether their report would be communicated to the House.—Mr POWELL WILLIAMS: Milk from the camp farm dairy is supplied, if desired to the canteens at Aldershot and also to officers and married non-commissioned officers and men. The farm was inspected quite recently by Dr Andrews, who is sanitary officer and pathologist to the Medical School of St. Bartholomew's Hospital and who was selected for the duty at the recommendation of the medical officer of the Local Government Board. His report has not yet been received, but it is understood that he has formed a very favourable opinion of the sanitary state of the dairy and farm. The report will be laid upon the table without unnecessary delay.—Mr JOHN DILLON: Can the hon. Member say whether Dr Andrews drank any of the milk himself?—Mr POWELL WILLIAMS: I am not informed as to that, but I may say that Dr Andrews purchased some of the butter for consumption in his own family.

MONDAY MAY 11TH

Veneral Disease at Gibraltar

Mr GEORGE WYNDHAM, in reply to a question upon this subject, said that the report about Gibraltar had been received. It dealt among other matters with venereal disease. In respect of the garrison during the five years ending in 1897 the admissions averaged 290 per 1000 in each year, as against 152 at Malta and 170 in the United Kingdom. The average daily number in hospital was 28.3 per 1000, as against 16.3 at Malta and 15.0 at home. The report of the Committee was under consideration.

Proposed Factory and Workshop Legislation

Sir MATTHEW WHITE RIDLEY, in reply to questions, said that for some time he had been fully informed of the long hours worked in the fruit-preserving industry, and that he had already introduced certain provisions in the subject was desirable. He had a number of amendments to the law affecting laundries for introduction in connection with which he should like to deal. But he was unable at present to say whether he would include in the Bill.

Mr CHAPLIN
whether b

from the authorities of Queen Charlotte's Hospital, the St. Pancras Workhouse, and other similar institutions to whom he had made representations that the vaccination of infants within a few days of birth was undesirable and should be discontinued.—Mr T. W. BRISSEN (for Mr CHAPLIN) replied: The Local Government Board has been in further communication with the authorities of Queen Charlotte's Hospital with the view of giving effect to the views already expressed by the Board. It has not been deemed necessary to make any further communication to the other authorities referred to.

TUESDAY, MAY 9TH.

Experiments on Living Animals

Mr PAULTON asked the Home Secretary (1) whether certificates were issued to persons holding licences under the Cruelty to Animals Act, 1876, allowing them to make experiments on living animals without anaesthetics except during the initial operation (2) whether during later stages of the experiment the holder of such certificate would be at liberty, should he so desire, to keep the animal alive without the further use of anaesthetics for the purpose of conducting observations and dissections, and (3) whether he still adhered without qualification to his former official statement that certificates of exemption from the compulsory use of anaesthetics were only given for such operations as inoculations or hypodermic injections which were of a comparatively painless character.—Sir MATTHEW WHITE RIDLEY replied: The nature of the certificates referred to would be more accurately described as follows. Under the terms of Section 3, Sub-section 3, of the Act certificates are granted the effect of which is to exempt the holder from the obligation to kill the animal experimented upon before it recovers from the influence of the anaesthetic when killing the animal would necessarily frustrate the object of the experiment, and provided that the animal is killed as soon as that object is attained. I would add with reference to the second paragraph that the sole use of the certificate is to authorise the keeping alive of the animal after the influence of the anaesthetic has passed off for the purpose of observation and study. I should certainly not allow any certificate involving dissections or painful operations without the fresh use of anaesthetics. The statement mentioned in the third paragraph, to which I adhere without qualification had reference to a different class of certificates from those just dealt with—viz. certificates granting total exemption from the compulsory use of anaesthetics.

SALE OF FOOD AND DRUGS BILL

PROCEEDINGS IN THE GRAND COMMITTEE.

THURSDAY MAY 11TH.

The Grand Committee of the House of Commons on Trade met to-day with Mr JOHN ELLIS in the chair, and resumed the consideration of the Sale of Food and Drugs Bill, beginning with Clause 3 which says: It shall be unlawful to manufacture, sell, expose for sale or import any margarine which contains more than 10 per cent. of water or fat, and every person who manufactures, sells, exposes for sale or imports any margarine which contains more than that percentage shall be guilty of an offence under the Margarine Act 1887 and any defence which would be a defence under Section 7 of that Act shall be a defence under this section, and the provisions of the former section shall apply accordingly.

Mr KEARLEY moved an amendment to make possession of this margarine an offence. He did so he said, with a special view to cover the case of persons who used this falsified article for making confectionery.

Sir JOHN LING opposed the amendment as an undue interference with trade, and pointed out that people might have this animal fat or margarine not for introducing into food but for purposes of lubrication.

Mr BRYNOR JONES said he did not think the amendment strengthened the clause in any way for he saw no difference between exposing the article for sale and possessing it.

Mr ASCHOFF opposed the amendment because, in his opinion, it would bring within the scope of the clause railway companies who simply carried the article.

On a vote being taken the amendment was rejected by 16 to 15 votes. Mr JEFFREYS moved to insert 6 per cent. in place of 10 per cent. In foreign countries he said the percentage was less than 10 per cent. In Belgium it was 5 and in Denmark 3 per cent. while in Germany all mixtures were prohibited.

Mr R. G. WEBSTER objected to any restriction upon mixtures on the ground that restriction meant interference with the trade in margarine.

Mr ASCHOFF said he had made a trial of a mixture of butter and margarine and found it an excellent condiment to food. In a matter of this kind they had to consider not merely the interest of agriculture but that of the whole community and he submitted that there should not be this interference with what was a legitimate business.

Mr GEORGE WHITKLEY spoke in the same line.

Sir JOHN LING presented the case of margarine manufacturers in this country. He said 600 tons of margarine was manufactured in this country each week and taken at 240 per ton this represented a value of about £1,200,000 per annum. The capital invested in the business amounted to £1,500,000. While the home manufacture was steadily increasing the importation of the foreign article was on the wane, 1,109,000 cwt. having been imported in 1894 and 894,000 cwt. in 1898. The hon. member argued that the making of margarine benefited agriculture in many ways. He cited the opinion of Mr. Armour of Chicago that it had added £1 per head to the value of cattle both in an increased States and in this country and stated that it had led to an increased demand for milk. The 10 per cent. limit of butter fat was, he said, a fatal blow at the home trade. All previous legislation of this kind had been based upon a consideration for health, but no one ventured to say that mixtures of butter and margarine were injurious to health. Not only so but this was the first attempt in modern legislation to pass an enactment whereby one class of manufacturer was compelled to depreciate the quality of his products in order that an improved market might be established for another class of manufacturer.

Mr WALTER LONG asked the Committee to stand by the proposed limit of 10 per cent. He believed that there was no greater fallacy than to imagine that the effect of this limit would be to necessitate the production of an inferior article. There was abundant scientific evidence of the highest and most reliable character to show that the very best quality of margarine could be produced with this limitation of 10 per

NORTH WEST LONDON HOSPITAL, Kentish Town-road, N.W.—Dental Surgeon. Also Assistant Resident Medical Officer for six months. Salary at the rate of £30 per annum.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with rooms, commons and washing.

ROYAL BERTS HOSPITAL, Reading.—Assistant Surgeon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Hunterian Professor, the Erasmus Wilson Lecture, and the Arris and Gale Lectures for the ensuing year. Also election to the Court of Examiners.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London.—Resident Medical Officer for six months. Salary at the rate of £80 per annum, with furnished apartments, board, and washing.

ROYAL MINERAL WATER HOSPITAL, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments in the hospital.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor Isle of Wight.—Assistant Resident Medical Officer unmarried. Salary £50 per annum, with board and lodging in the hospital. Applicants to the Board of Management, London Office, 34 Craven-hill, Charing Cross.

ROYAL ORTHOPEDIC AND SPINAL HOSPITAL, Birmingham.—House Surgeon.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street Strand W.C.—Clinical Assistants for six months.

ST PETER'S HOSPITAL FOR STROKE, &c., Henrietta-street, Covent Garden.—House Surgeon for six months. Salary at the rate of £100 a year with board, lodging, and washing.

STAMFORD HILL AND STOKES NEWINGTON DISPENSARY 123, Epsom-street, Stoke Newington N.—Junior Resident Medical Officer. Salary £100 per annum with board and residence.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon. Salary per mensem, with board washing, and residence.

TOWNSHIP OF TOXETTH PARK.—Senior Assistant Medical Officer. Workhouse and Infirmary. Salary £125 per annum, with board, washing and apartments. Subject to statutory regulations. Applications to the Clerk to the Guardians, 15, High Pavement, Liverpool.

UNIVERSITY COLLEGE, London.—Jodrell Professorship of Lecturing.

VICTORIA UNIVERSITY THE LANCESHIRE COLLEGE, Leeds.—Demonstrator in Pathology. Salary £120.

WEST RIDING ASYLUM Wadley, near Sheffield.—Fifth Senior Medical Officer. Salary £100 per annum, rising £10 a year. £150, with board, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Governor and Secretary unmarried, or widower with family. Salary £170 a year with board, washing and residence in the institution.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

EDITORIAL NOTICES

It is most important that communications relating to the editorial business of "THE LANCET" should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the editorial staff. It is urgently necessary that attention be given to this notice.

Notes, Short Comments, and Questions

It is especially requested that early intelligence of local agents having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Teachers, original articles, and reports should be written on one side of the paper only, and when accompanied by blocks it is requested that the name or the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication. We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor." Letters relating to the publication, rate, and advertising department of THE LANCET should be addressed "To the Manager." We cannot undertake to return MSS not used.

MEDICAL EVIDENCE AT CORONERS INQUESTS"

To the Editors of THE LANCET

SIRS—In your article on the above subject in THE LANCET of April 22nd you point out that the utility of inquests is frequently limited by the absence of medical evidence and that the remedy for this is that the coroner should always be a medical man. I feel sure that you do not hold that the coroner should supplant the medical witness at the inquest, but I fear that this is what frequently happens when the coroner is a medical man at any rate, in my district medical evidence is rarely required at inquests as the coroner supplies it himself being a member of the medical profession. The preliminary inquiry in cases of sudden death is made by a village constable sometimes a raw youth who has been in the police force only a few months, and on his report the coroner decides whether he will hold an inquest or not. The following are a few examples of cases which have occurred lately—1. A man who had been in good health was suddenly taken ill the friends sent for a medical man who on arrival found the patient dead. An inquest was held there was no medical evidence and no communication with the medical attendant. 2. A child who had been attended and supplied with medicine by a schoolmaster suddenly died. Investigation was made by the parish constable there was no inquest. 3. A child was taken ill with diarrhoea the father called on a medical man and obtained a bottle of medicine he did not request the medical man to visit his child the child died. Investigation was made by the parish constable. An inquest was held there was no medical evidence and no communication with the medical man. 4. A man was found dead in bed he had not been attended or seen by a medical man. An inquest was held. There was no medical evidence. 5. A boy fell into the water and was immersed for 10 minutes. No medical man was sent for the boy died. An inquest was held. There was no medical evidence. 6. A man while crossing the railway was knocked down by a train and killed. No medical man was summoned. An inquest was held. There was no medical evidence. The remedy I suggest is (1) that in every case of sudden death a medical man should inspect the body and draw up a report of the circumstances attending the death, which report should be forwarded to the coroner and (2) at every inquest the medical man who has made the investigation should be present to give his evidence.

I am, Sirs, yours faithfully

April 30th, 1899

REFORM

THE NEW EYESIGHT SPECIALIST

In the *Annus Medicus* of 1898 (THE LANCET, Dec. 31st, 1898, page 1779) we said that the issuing of diplomas by the Worshipful Company of Spectacle Makers was not likely to lead to friction between the surgeon and the optician. The ophthalmic surgeon in our view would be content to know that some of the patients who would have applied to him have gone to the optician, for the optician with larger information than he had previously would recognise the numerous cases requiring a different kind of knowledge from that possessed by him and would if wise, transfer them to the ophthalmic surgeon. Such a position would, in our opinion, result in no loss to either surgeon or optician and in benefit to the patients. The four months which have elapsed since writing to this effect have brought us no evidence directly that we were premature in expressing our views.

But the list of names appended to the memorial to be presented by the Corporate and Medical Reform Association to the General Medical Council—which memorial objects strongly to these diplomas for opticians—would seem to indicate that ophthalmic surgeons take a different view to the one which we anticipated for them. That list includes the names of Mr. Bradley ophthalmic surgeon to Guy's Hospital, Mr. Critchett and Mr. Juler ophthalmic surgeons to St. Mary's Hospital, Mr. Work Dodd, ophthalmic surgeon to the Royal Free Hospital, Mr. Frost, ophthalmic surgeon to St. George's Hospital, Mr. Hartridge ophthalmic surgeon to the Westminster Hospital, Mr. Jessop, ophthalmic surgeon to St. Bartholomew's Hospital, Mr. McHardy, ophthalmic surgeon to King's College Hospital, Mr. Nettleship, ophthalmic surgeon to St. Thomas's Hospital, Dr. Argyll Robertson consulting ophthalmic surgeon to the Edinburgh Royal Infirmary, Mr. Sydney Stephenson ophthalmic surgeon to the Kewlinas Hospital and Dr. Bell Taylor surgeon to the Notting ham and Midland Eye Infirmary. It is clear that this representative body of ophthalmic surgeons consider that their professional position is encroached upon by the education of opticians up to a certain standard, and their opinion is one which we do not desire to disregard.

As a matter of fact the subject has been approached by the Corporate and Medical Reform Association and by ourselves from different points of view and we think that ours is the more practical one. So far as the general practitioner is concerned we do not believe that he has suffered or will suffer material harm. The question whether certain work will now be done by laymen openly which has for a time of indefinite length been done by those laymen secretly and upon the one that we did not enter upon for it seemed in its nature. Theoretically all pathological to the eye should be submitted to and answered inasmuch as ophthalmology is a province by we believed that the educated optician for eye cases, his sound modicum of

knowledge enabling him to see what case falls within his sphere and what should be sent on to the surgeon. We are in complete agreement with all who consider that it is an act of impudent usurpation for the possessor of the diploma of the Worshipful Company of Spectacle Makers to arrogate to himself the position of the ophthalmic surgeon or the medical man. The Company had nothing of the sort indicated by the following paragraph and advertisement in view, we may be certain when they decided to institute an examination of diplomas—

I The Paragraph.

LOCAL SUCCESS.—Mr. Hayden B.O.A., F.S.M.C. (Lond.) ophthalmic optician and eyesight specialist, of 28, Market-row has just successfully passed an examination under Mr. G. Lindsay Johnson, M.A., B.Sc. F.R.O.S., Professor Silvanus Thompson, D.Sc. F.R.S., and Mr. G. Paxton, held by the Worshipful Company of Spectacle Makers London and in consequence has been granted a diploma of Fellowship of the Company, and has been admitted a Freeman of the Company and also a Freeman of the City of London. This is a distinction, we believe, no one else in Larnmouth possesses, and was the second gentleman to be presented with the freedom of the city after the Siridar, Lord Kitchener of Arpell and Khartoum.

II The Advertisement.

MR HAYDEN,

B.O.A. F.S.M.C. (Lond.),

OPHTHALMIC OPTICIAN,

AND

EYESIGHT SPECIALIST,

QUALIFIED OPTICIAN BY EXAMINATION

CONSULTATIONS AND SIGHT TESTING FREE DAILY

The only Registered and Certificated Optician in Yarmouth

Mr. Hayden attends personally from 9 till 7 daily Thursdays till 2, at his Consulting and Sight-testing Rooms,

28, MARKET ROW, YARMOUTH

Mr. Hayden's methods for examining the Eyes and testing the Sight are on the most modern and up-to-date principles, the same as practised by the leading

LONDON OPHTHALMIC SURGEONS.

ARTIFICIAL HUMAN EYES CAREFULLY MATCHED AND FITTED.

Why do you consult a Quack Optician? You would not consult a quack doctor or allow a Pedlar to give you Medicine

This sort of thing was not contemplated either by the Worshipful Company of Spectacle Makers or by ourselves. We draw attention to Mr. Hayden's comparison of his methods with those of the "Leading London Ophthalmic Surgeons," and we recommend the Company to provide themselves—if they have not already done so—with the legal machinery for taking away their diplomas from persons who make an improper use of them. It is quite wrong that advertisements in such terms as the one we have just quoted should appear. Their phraseology is an insult to the medical profession, and does injustice to other opticians. Opticians who do not possess diplomas are not quack opticians, and it is advisable that the Worshipful Company of Spectacle Makers should repudiate any belief in such a view.

'POISON BOTTLES'

MR. E. MILTON SMALL of New Brompton, Kent, calls our attention to an inquest held at Maidstone on Tuesday, April 18th, on the body of a Henrietta Amelia Stanton, aged 47 years, whose elster gave her a like horn in mistake for medicine, the two bottles standing together on a table by the bed, and states that he has applied for a provisional patent suggesting that the lip of poison bottles should be brought down and joined to the side or shoulder so as to form the letter P and as an additional precaution "P for Poison," he says "might be moulded on the shoulders of the bottles. If P for Poison became household words the very feel of the handle would send a thrill into the heart of a person attending on a patient and waken into intelligence the most over-wrought. The construction of the bottle would make it distinct in the dark and would therefore be better than the use of blue glass or red labels. The suggestion is worthy of attention, but experience proves that something more than a peculiarity in the shape of the bottle is necessary if accidents are to be avoided.

'SUPERFLUOUS HAIR'

To the Editors of THE LANCET

SIRS—In THE LANCET of April 29th "M.D." asks for advice as to the treatment of a young lady who is growing a moustache and desires suggestions to remedy this great annoyance. She had better resign herself to the maculine method of removing undesired hair and learn to shave. As her hair is dark she will need to shave every day and surely there can be no reproach or violation of delicacy in such an expedient. Electrolysis in cosmetic surgery is of infinite use in the removal of hairy moles and other blemishes, such as nevus and

the winds of the Atlantic and have no shelter, but are much more sunny than our coasts. A recession is different—it does not lie on the actual coast but on a large inland basin which communicates with the Atlantic by a channel. It is protected by large pine-forests which cover the dunes over the houses of the so-called "The d'Hiver," are spread. It reminds us somewhat of Bournemouth.

INLAND CLIMATIC HEALTH RESORTS

[illegible]

with the seaside places on the German coast—viz., Borkum, Nordney, Baltrum, &c., and the islands of, Helligoland, Foehr, and Sylt. All these foreign localities have excellent sands for bathing. Some of them offer a gayer and more amusing life and altogether a peculiar charm which partly depends on the greater brightness and transparency of the atmosphere. These remarks apply especially to Ostend, Scheveningen, and Deauville and at all of them the English visitor meets with a greater change of food, accommodation, people, and manners and customs—circumstances which render such foreign places in certain cases preferable. To some families it is also an advantage that their children can learn a foreign language. In Denmark, Klampenborg, near Copenhagen, and Marienlyst, near Helsingør, are popular summer resorts. Somewhat different from ordinary seaside resorts are the places on the Baltic, being less stimulant but mostly provided with beautiful forests in their immediate neighbourhood. Düsternbrook, Travemünde, Doberan, Warnemünde, the island of Rügen (Patbus), Heringsdorf, Swinemünde, Misdroy, Colberg, Rügenwalde, Zoppot, and Cranz may be named. We may mention here that the example given by England in Margate and a few other places as to seaside hospitals, sanatoria, and convalescent homes is being largely followed on the continent. The French, so far as I know, were the first to move in this important matter on the continent. The Assistance Publique de Paris established, as far back as from 1860 to 1870, the sanatorium for scrofulous children at Berck sur Mer, the *Œuvre des Hôpitaux Marins* established similar institutions at Banyuls-sur Mer (Pyrenées Orientales) and at Saint Trovan (in the Island of Oléron), and there are besides sanatoria at Saint Pol sur Mer, at Pen Bron (near Le Croisic), at Arcachon, and at Hyères. In Germany the Society for Children's Sanatoria at German Seaside Places has sanatoria at Norderny, at Wyk, on the Island of Foehr, at Gross-Müritz, and at Zoppot. This is a subject of great public importance and well worth the attention of philanthropists and charitable societies. England, which first set the example, ought to be and to remain in front of other nations in this useful work.

Marine winter resorts.—With regard to these we cannot claim for England the same predominance as we have done for summer resorts. Although, as we have already said, the east coast is very useful to many cases also in winter we should not be justified in calling any places "winter resorts" excepting perhaps a few small sheltered spots, the largest of which is at St Margaret's Bay, near Dover. The principal localities are on the south east, south, south west, and west coasts. The furthest to the east are Hastings and St. Leonards. These places are scarcely warmer than London, but the South Downs which send forth a high spur to the sea give to them considerable shelter from the north, north-west, and north east. They are drier and more stimulating than most places further to the west, but they suffer from keen east winds during spring and are at that period not suitable to delicate invalids. Brighton is too much exposed to the east winds, but it has at least one fairly sheltered walk, and could, by means of grand artificial screens and nobly arranged winter gardens, be rendered more useful to a great number of health seekers. Dr Ewart⁵ justly remarks in his report on Sussex "that various climates may really be found within Brighton." The autumn and first half of the winter offer to the inhabitants of London the greatest advantages. Brighton is then decidedly warmer than London, especially at night, and is mostly free from mist although the large increase of houses and population has led to a kind of smoke fog on windless days. Southsea has fairly mild winters and Ventnor, on the Undercliff of the Isle of Wight, maintains its reputation by the very fair results obtained at the Royal National Hospital for Consumption and in the town itself. Bournemouth and Boscombe have in addition to the shelter afforded by their situation the advantage of their fir plantations, but patients entirely confined to their rooms and the air sometimes too still. Salcombe Sidmouth, Budleigh Salterton, Exmouth, Dawlish, and Teignmouth have fairly warm and equable winters, but their sheltered grounds are rather limited, while Torquay, owing to its bay being surrounded by three high hills, has a much larger space for exercise; not only on level but also on rising ground, from which a variety of the most beautiful views can be obtained. The Channel Islands are characterised by Dr Symes Thompson and Dr Lazarus-Barlow⁶ as "mild,

moist, and relaxing," but they are rather too windy to be used often as winter climates. Jersey is more protected than Guernsey. Rachitic children are very favourably influenced by this climate. Further west Falmouth and Penzance possess perhaps less shelter than Torquay, but they have, as their vegetation, manifests, comparatively very mild winters, and in spite of a certain degree of humidity they exercise, on most persons, a decidedly tonic influence, and many persons even in advanced age suffering from winter coughs enjoy great freedom from their trouble at these localities and are able to spend on most days several hours in the open air. I need scarcely remind you of the favourable descriptions of Falmouth and Penzance given by Sir E. Sieveking⁷ and Sir Joseph Kayser⁸. Dr W. H. Dickinson⁹ likewise speaks in favourable terms of Falmouth. The deaths from tuberculosis are somewhat fewer at Falmouth than at Penzance, but Dr Dickinson points out that this may be due to the older reputation of Penzance attracting a larger number of tuberculous immigrants. The Scilly Islands, although their climate is very mild and equable, are too much exposed to wind to be suitable to the treatment of phthisis, and they are as yet scarcely used therapeutically. The sea voyage and the isolation of the islands are great drawbacks. The north coasts of Cornwall and Devonshire are as yet not regarded as winter resorts, but St Ives and Ilfracombe have in winter certain advantages, although they are less warm and more exposed to wind than the best places on the southern coasts. It is a frequent complaint of sufferers from rheumatism that these troubles are aggravated in Devon and in Cornwall. Minehead and Weston super Mare are resorted to almost only in summer, but bronchitic cases mostly do well there up to November and even to December and Dr Mitchell Bruce¹⁰ in his description of Somerset shares this experience. On the north coast of Cardigan Bay, in North Wales, Pwllheli deserves attention on account of its protection from cold winds. Llandudno, though principally a summer resort, offers also advantages in autumn and spring and to hardier invalids even in winter. More northwards, Grange, on Morecambe Bay, has fair shelter and can be used as a winter resort, and Rothesay, on the Isle of Bute, a favourite summer resort, has mild and equable winters, but it is too humid for most invalids, excepting chronic bronchitic cases. The same is still more the case with the Shetland Islands. Glengarriff and Queenstown in Ireland have fair claims to be regarded as winter climates, but they both belong to the equable and humid class. The physiological character of all the coast climates of Great Britain compared with continental places is that they are more or less bracing—those of the east coast eminently so, those of the south and south west less so, and those of the west of Scotland and Ireland still less. The climates of the south-west coast of England and of the west of Scotland and of Ireland are to be regarded as sedative. They are generally called "relaxing," but this is not quite correct, as they are only so to a very limited class of persons who cannot bear a soft and humid air. On a large number of people these sedative climates exercise a more strengthening influence than those of the east coast. Some people complain of indigestion and biliousness, but as soon as they diminish the amount of their food, especially of meat, limit that of stimulants, and take some slight aperients and regular exercise, the indigestion and biliousness go away and do not reappear.

In comparing the marine winter climates of Great Britain with those of the Riviera, with those of Palermo, Catania, Aci Reale, and Taormina in Sicily, with Malaga, and with Corfu, our climates are wanting in sunshine, sun warmth, and in clearness of atmosphere and sky, and they have a greater number of rainy days and hours. There is also much more shelter from cold winds on the Riviera, and the direct sun warmth is there increased by the reflection from the rocks and the sea. These defects of our climates are to some persons so serious that they cause mental depression and the bodily health may even suffer from this cause. Intermediate between the comparative but by no means unbearable dulness of our coast climates and the luxuriant sunshine with shelter of the Riviera are some localities on the south-west coast of France—viz., Biarritz, St. Jean de Luz, and Arcachon. The two former are quite exposed to

with the seaside places on the German coast—viz., Borkum, Nordney, Baltrum, &c., and the islands of Helligoland, Foehr, and Sylt. All these foreign localities have excellent sands for bathing. Some of them offer a gayer and more amusing life and altogether a peculiar charm which partly depends on the greater brightness and transparency of the atmosphere. These remarks apply especially to Ostend, Scheveningen, and Deauville and at all of them the English visitor meets with a greater change of food, accommodation, people, and manners and customs—circumstances which render such foreign places in certain cases preferable. To some families it is also an advantage that their children can learn a foreign language. In Denmark, Klampenborg, near Copenhagen, and Marienlyst, near Helsingør, are popular summer resorts. Somewhat different from ordinary seaside resorts are the places on the Baltic, being less stimulant but mostly provided with beautiful forests in their immediate neighbourhood. Düsternbrook, Travemünde, Doberan, Wismar, &c., are adopted on account of their proximity to the sea and the character of the climate. In selecting a locality we must always bear in mind not only the purely climatic qualities of the place but also the nature of the accommodation there, including the cooking, the class of people frequenting it, the social conditions and amusements, and the manner in which the sum total of agencies, climatic and social, is likely to influence the person who asks our advice. Our wish should be that the invalid should derive as much benefit as possible. If we have reason to think that he or she will be satisfied with the best climatic conditions, good medical advice, and fair accommodation alone, our decision will be comparatively easy. If, however, we have to deal with an invalid to whose mental condition the amusements and all the social aspects of a place are essential, we must endeavour to find one where these are combined with good climatic and hygienic qualities, and we may have even to sacrifice some climatic advantages for certain invalids if we have reason to suppose that they will become depressed and unhappy at a certain climatically suitable place. Experience abundantly shows us that, however good the climatic elements may be, mental dulness causes in certain types of people manifold functional troubles, such as want of appetite, dyspepsia, imperfect action of the bowels, weakness and irregularity of the heart's action, inability to take exercise, sleeplessness, and loss of weight. Every one of you has probably met with persons who are happy, who can work, who can take exercise, who eat and sleep, who have a clear urine and regular action of the bowels, and who gain weight, if they are at a warm and sunny locality and have flowers and music, while on the contrary they become depressed, they lose their appetite, they become sleepless, they cannot work, they have a urine loaded with lithates, they lose weight, or they occasionally become morbidly fat, if they are obliged to be at a locality which is cold, damp, misty, sunless, and without music, flowers, or butterflies. There are many persons, principally so-called "people without nerves," who cannot understand and appreciate such differences in the condition of delicate persons. These conditions, however, are not imaginary, they are fearfully real and ought not to be overlooked in giving advice about climatic resorts. Such conditions as these must move sometimes the balance in favour of continental places, although we know that, were it not for the invalid's peculiar mental conditions and tendencies, an English resort would be equally good or even preferable. For these reasons it is important to make our English resorts as agreeable as possible by accommodation, food, music, promenades, and shelters.

Many other circumstances partly hinted at before, which have nothing to do with purely climatic matters, demand our consideration. There are, for instance, nervous persons who become excessively frightened by very slight functional disorders and, in consequence, become almost sleepless and sometimes sick and really ill, until they can be reassured by a medical attendant who has their confidence. In such cases we must always think of a place where a medical man resides who is likely to be sympathetic to our invalid, and to gain authority over the patient and to use it for his good. In such cases the medical man is of the first importance. The climatic resort may not have any specially good qualities, but the mental influence exercised by the medical adviser will more than balance the climatic defects of the place. The physician is, indeed, a very important part of every health

moist, and relaxing," but they are rather too windy to be used often as winter climates. Jersey is more protected than Guernsey. Rachitic children are very favourably influenced by this climate. Further west Falmouth and Penzance possess perhaps less shelter than Torquay, but they have, as their vegetation manifests, comparatively very mild winters, and in spite of a certain degree of humidity they exercise, on most persons, a decidedly tonic influence, and many persons even in advanced age suffering from winter coughs enjoy great freedom from their trouble at these localities and are able to spend on most days several hours in the open air. I need scarcely remind you of the favourable descriptions of Falmouth and Penzance given by Sir E. Sieveking and Sir Joseph Kayser. Dr. W. H. Dickinson likewise speaks in favourable terms of Falmouth. The deaths from tuberculosis are somewhat fewer at Falmouth than at Penzance, but Dr. Dickinson points out that the judicious and properly restriction of Penzance which not pleasurable on our senses. Such means as these stimulate the circulation in the brain and we often succeed more or less in improving by them the nutrition of this organ which again acts most powerfully on the heart and on the blood vessels, especially the vaso-motor portion, and often effects very remarkable changes in all the organs of the body and causes improvement or cure of many chronic ailments.

ON THE RESPECTIVE PARTS TAKEN BY THE URINE AND THE FÆCES IN THE DISSEMINATION OF TYPHOID FEVER

BY P. HORTON SMITH, M.A., M.D., CANTAB., F.R.C.P. LOND., ASSISTANT PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION, BROTHAM, AND TO THE METROPOLITAN HOSPITAL, ASSISTANT MEDICAL TUTOR, ST. BARTHOLOMEW'S HOSPITAL. (From the Public Health Laboratory, St. Bartholomew's Hospital.)

At the present day the view that typhoid fever is propagated by means of the excreta is unanimously held. It is probable also that in the opinion of the great majority the fæces are still regarded as the chief, if not the sole, means whereby the dissemination of the disease takes place. Now, it is, of course, true, that the fæces are to a considerable extent responsible for spreading the disease, but recent work has shown that another excretion—namely, the urine—is often intensely infectious in typhoid fever, and that it therefore must play a great part in spreading the disease. From a hygienic point of view it is obviously of great importance that we should be able to estimate, even approximately, the danger of infection which may be expected from each of these excretions, and especially that we should have accurate knowledge as to the period of the disease at which each attains its maximum virulence. It is proposed therefore in this paper to sum up the actual state of our knowledge concerning the infectious nature of the urine and fæces respectively, at the same time adding some further observations which bear upon this subject.

PART I.—THE FÆCES

Before stating the results of the latest observations which have been made on typhoid stools it will be well to recall some of the earlier ones, for it is upon these—though now known to be incorrect—that the present general idea of the intensely infectious character of typhoid stools throughout the whole course of the disease in reality depends. The typhoid bacillus was discovered by Eberth in 1881 and first cultivated by Gaffky in 1884. Gaffky himself did not profess to be able to demonstrate the presence of the bacilli

The expenses in connection with this research were in part defrayed by a grant from the Royal Society. It is not contended of course that other matters, such as spasm or pus, may not occasionally be of benefit, but dissemination through them must be extremely rare and need not now be discussed.

Virchow's Archiv, 1883, Band lxxxi.; 1881, Band lxxviii. Mittheilungen aus dem Kaiserlichen Gesundheitsamt, 1884, Band ii.

unmistaken, though how soon they become absolutely harmful cannot as yet be settled by bacteriology. Finally, when typhoid bacilli have been described in the feces long after defecation—e.g., in Lazarus's case, 41 days after—we are dealing almost certainly with faeces contaminated with urine and not with pure faeces.

PART II—THE URINE

The possibility of the urine being infectious in typhoid fever is not altogether a recent suggestion. The view seems to have been originally put forward by Seitz in 1886 and since this date various other observers have drawn attention to the subject. As I pointed out, however, in a paper communicated to the Royal Medical and Chirurgical Society in 1886—no definite reliance could be placed on any of the observations for the simple reason that the tests up to that time applied to the isolated bacilli were not sufficient to differentiate them from bacilli coli communis and that many of the so-called typhoid bacilli obtained from urine were in all probability nothing more than colon bacilli. I showed, however, from observations then recorded (1) that after eliminating this source of error, without doubt in some, though not in all, cases of typhoid fever true typhoid bacilli do occur in the urine, also (2) that "when the bacilli do occur they only occur towards the end of the disease—that is to say, during the third week or later, their presence, therefore, could rarely if ever be of assistance in diagnosis", and (3) that "when they are present in considerable numbers such urine be dried and stained the bacilli may be seen under the microscope, occasionally also the urine may be rendered turbid by the enormous quantities of bacilli passed."

These results being unexpected, but nevertheless, if true, of some importance, it becomes interesting to inquire whether they are borne out by later observations. This indeed has been the case. Thus Richardson, in 1898, working in Professor Wright's laboratory in Boston, examined the urine of 38 cases of typhoid fever, and in nine of them—i.e., in 24 per cent—found the typhoid bacilli. He also concluded "that when they do occur they are always present in large numbers and in practically a pure culture, and that they first appear in the later stages of the disease and persist often far into convalescence." It will be seen at once that these independent results of Richardson almost exactly agree with my own conclusions.

With regard also to the possibility of such enormous quantities of typhoid bacilli occurring in the urine as to render it turbid we have direct confirmation given by the observations of Richardson. He examined 50 typhoid urines with regard to this point alone and in three of them he found this dangerous phenomenon to occur. Thus he found that in one case the urine became "turbid with bacilli" towards the end of the attack and remained so for 10 weeks, only ceasing to contain typhoid bacilli seven weeks after final defecation. In the second case the turbidity first occurred 10 days after defecation and the bacilli continued present for four and a half weeks. Lastly, in the third case the bacilli were first observed six days after the temperature had become normal and remained present in this case only eight days. There can, therefore, no longer be the slightest doubt that typhoid bacilli may not very frequently occur in the urine in extraordinary quantities—in one of Richardson's cases, indeed, they amounted to 172,000,000 bacilli in each cubic centimetre of urine. As, however, the condition is not yet fully recognised it may be well to record yet another example of it, in this case associated with a certain amount of pyuria. I am much indebted to Sir Dyer Duckworth for his kind permission to publish notes of the case. They are as follows. "The patient, aged 22 years (referred to in Table I as Case 3), was admitted into St Bartholomew's Hospital on Oct. 28th, 1898, suffering from typhoid fever, this being the eighth day of his disease. On admission his temperature was 104° F., he was somewhat deaf and also rather drowsy. There was a most copious eruption of rose spots. The abdomen was a little distended and the patient complained of slight abdominal pain. The spleen was not felt. The urine was acid and contained no albumin. Next day the

Bakteriologische Studien zur Typhus-Aetiologie, München, 1897.
22 Transactions of the Royal Medical and Chirurgical Society.

24 Centralblatt für Bakteriologie, vol. XXII, April, 1898.

serum reaction was obtained at a dilution of 1 in 200. The fever ran its usual course, remaining up for some time and then gradually falling by 19° F. The temperature then remained down for nine days, but on the tenth day (Nov. 20th) it began to rise again and the patient had a mild relapse. This lasted from Nov. 20th to Dec. 4th, after which the temperature remained down for good and the patient made a rapid recovery. The condition of the urine was as follows. It was natural on admission and apparently remained so until the day before the relapse on Nov. 18th. On this date, however, it was noticed that the urine though still acid contained pus and also showed a cloud of albumin. A bacterial examination was, however, made. The pyuria was unaltered throughout the relapse and on Nov. 29th the urine was examined in greater detail. It was then found to be neutral, to contain a cloud of albumin and also a little pus, enough to form a slight sediment at the bottom of the urine-glass. It was, however, also turbid, a condition not due to the small amount of pus present but to the fact that under the microscope it was found to be swarming with bacilli. These on cultivation answered correctly to all the tests enumerated at the commencement of this paper and proved themselves to be, therefore, a pure culture of the typhoid bacillus. On Dec. 3rd, the last day of the relapse, the condition of the urine was unchanged, except that the bacilli in the urine were now all "clumped." There had been no indication of this on Nov. 29th, but now it was very marked (vide Fig. 1). On Dec. 6th the temperature had been normal for two days. The urine still contained a little pus, a faint cloud of albumin, and many typhoid bacilli, still in clumps (vide Fig. 2). A week later, however, the condition had altered, for on Dec. 13th the urine was clear, neutral, 1012, and contained no albumin, no bacilli, or pus. On Dec. 17th the urine was again examined. It was natural, contained no albumin or pus, and cultures again showed the absence of typhoid bacilli.

FIG. 1

A drop of the urine in Case 3 passed on Dec. 3rd (the last day of the relapse) dried on a cover-glass and stained. Innumerable typhoid bacilli in large clumps are seen also many pus cells. (Photographed by Dr Norman X 400)

It will be seen, therefore, that in this patient the pyuria began on the thirteenth day of the disease, just before the commencement of the relapse, lasted through the relapse, and persisted for some few days into convalescence. On three occasions on which the urine was examined bacteriologically during this condition it was found to be swarming with a pure culture of typhoid bacilli, and it is probable also that the latter made their first appearance with the pus on Nov. 18th, for the urine was then first noticed to contain bacilli, though their real nature was not recognised until later. Moreover, the bacilli persisted into convalescence.

the one taken shortly before a relapse occurred In the other 19 stools no typhoid bacilli could be demonstrated
Consideration of results—There are not many observations which it is possible to compare with the above, for workers in this field have for the most part confined themselves to the early periods of the disease Those also which may be collected from the literature must to a certain extent be discounted when positive, owing to the faeces not having

* — signifies a positive result, typhoid bacilli being found in the stools. — signifies a negative result, typhoid bacilli not being found T N = Temperature normal.

REMARKS.—*Case 1* was a very mild attack of typhoid fever. The temperature reached the normal on the sixteenth day.—*Case 2*. The attack was severe, in that the fever lasted for 32 days. Later phlebitis occurred. There was no diarrhoea and no typhoid state.—*Case 3*. The attack lasted 21 days and was followed by a relapse. Pyuria was present from Nov 19th to Dec 6th. There were many typhoid bacilli in the urine during this condition, but none in the faeces.—*Case 4*. This was a severe attack, the temperature remaining high for 35 days. There was much diarrhoea.—*Case 5*. The patient had a long attack followed after an interval by a long relapse.—*Case 6*. The patient had an attack of moderate severity followed by one relapse.—*Case 7*. In this case the temperature reached normal on the twenty-ninth day

been carefully separated from the urine, a serious source of error thereby being introduced. With this reservation it may be noticed that Jemma,¹⁸ in addition to his numerous positive observations within the first two weeks of the disease, also had two positive results on the fifteenth and eighteenth days but six negative results on the twenty second, twenty-fourth, twenty seventh, thirtieth, thirtieth, and thirty third days respectively, and also once in a relapse two days before the temperature reached normal. Pollak¹⁹ also quotes three positive results on the seventeenth, nineteenth, and twentieth days, and in two out of three cases was able to find the typhoid bacilli during a relapse. Lazarus²⁰ examined the stools of 16 convalescents and found the bacilli in the stools in only three, and lastly, Richardson,²¹ who examined 23 stools from 13 convalescents, was only able on one occasion

(the day, following final defervescence) to find the typhoid bacilli. All the other stools yielded a negative result.

It will be noticed, therefore, that former observers also found considerable difficulty in demonstrating the typhoid bacilli in the stools late in the disease and during convalescence—a fact which is brought out more clearly when we remember that probably in many of their so-called positive results the bacilli found were not really in the faeces but in the urine. It would seem, then, from a consideration of all the cases that we are justified in stating that it is extremely difficult and as a rule impossible to find the typhoid bacilli in the stools in the later periods of the disease (unless in connexion with the commencement of a relapse) and also during convalescence, though in the early stages they can as a rule be found with comparative ease. Negative results, however, such as these are notoriously fallacious. We must therefore consider them very carefully to see what conclusion may legitimately be drawn from them. The question to be answered, in fact, is this: Are we justified in concluding that because typhoid bacilli cannot be found in the stools in the later stages of the disease and during convalescence therefore they are really not there?

To this question a negative answer must be at once returned. We must remember first that our method for demonstrating the typhoid bacilli in stools is at the best unsatisfactory. It consists, as we have seen, in taking a trace of the stool and then diluting this in broth and finally making plates with this dilution, thus great dilution being necessitated by the enormous quantities of colon bacilli present, so that were it not done the individual colonies could not grow isolated from each other and thus be distinguished. Now, it is obvious that unless the typhoid bacilli were present in considerable numbers they might easily escape detection since they might fail to be present in the minute trace of stool which alone we are able to examine. (Thus, for example, must almost certainly be the explanation of the failure to find the typhoid bacilli on the eighteenth and twenty first days of Case 3, since four days later, previously to a relapse, a recrudescence occurred and they were again present in large numbers.)

Again, in support of the views that the bacilli are very probably present in the stools in small quantities for some considerable time after they cease to be demonstrable there is the fact that post mortem typhoid bacilli can often be found in the gall bladder even in pure culture—at a time, that is to say, when they can no longer be found in the faeces. Now, these would almost certainly pass with the bile into the intestinal canal and hence might reasonably be expected in the faeces. This argument, however, must not be pressed too far, for it was shown some little time back by Walthelet that if colon and typhoid bacilli were grown together in broth in a very short time the colon bacilli alone survived, and again, that if the typhoid bacillus was inoculated into a broth tube containing the toxins of bacillus coli it would not grow and speedily died. Now these are not unlike the conditions which obtain in the alimentary canal in typhoid fever. It is well known that in this disease the virulence of the colon bacillus becomes greatly enhanced, and it may be that when the disease has run a certain course the typhoid bacilli may in favourable cases be first impeded in their growth and finally rapidly destroyed in the intestinal tract through the action of the colon bacillus. If this be so our inability to find them in the stools later in the disease would find a ready explanation. This, however, as yet is speculation and at the present moment the following conclusions only would seem to be justified with regard to the presence of the typhoid bacilli in the stools.

General conclusions—The stools of a typhoid patient separated from the urine contain typhoid bacilli in fair quantities, demonstrable by our present methods up to about the beginning of the third week. After this date the number begins rapidly to diminish, so that our methods no longer avail as a rule to find them. If, however, a relapse occurs it may be preceded by a recrudescence of the typhoid bacilli which can then be found again in the faeces, but during the greater part of the relapse itself and throughout convalescence the typhoid bacilli cannot be found in the stools.

It follows from the above that the stools of a typhoid patient must always be regarded as highly infectious during the early stages of the disease, and may again become so in connexion with the commencement of a relapse. This highly infectious character, however, soon becomes greatly

6
The clinical course of these cases—It will be instructive to find out whether the typhoid cases in which the bacilli are found in the urine run a more severe course than those in which this phenomenon does not occur. Richardson is of opinion that this is the case, and certainly of the 15 cases mentioned above five died (a mortality of 33 per cent.), while of the 45 in which typhoid bacilli were not present in the urine only two died (or 4 per cent). It is very questionable whether these figures accurately represent the state of the case. Certainly it is that in the two cases in which the urine was "terrible," from the millions of bacilli present recovery took place in each. Moreover, in four of them the phenomenon occurred during convalescence, and throughout the whole duration the patients seem to have suffered from no undue symptoms whatever. This certainly was watching myself. During the occurrence of the bacilluria the case in the patient whom I had the opportunity of seeing should be unaffected by the occurrence of the typhoid.

7 *Or what does the condition depend upon?*—Unfortunately at present no definite answer can be given to this question owing to the lack as yet of post-mortem examinations in suitable cases. On the whole it would seem most probable that the condition is due to local changes set up in the kidney by microbes having been carried thither by the blood stream. It is, without doubt, not due to a mere filtration of typhoid bacilli out of the blood. The matter, however, requires further investigation.

are considered as arising at with regard to the infectious character of the urine in typhoid fever are as follows:—
1. It can no longer be doubted that typhoid bacilli occur in the urine of all typhoid patients, probably in about 25 per cent of all cases. 2. For the most part, though present in small numbers as to be demonstrated bacteriologically in such great cases, they are present in an undetectable quantity to the naked eye. 3. They are nearly always in pure culture. 4. They are generally retained for some weeks or even months. 5. The characteristic of the urine does not assist in the diagnosis of typhoid bacilli in the urine. 6. The prognosis of a case is not determined by the presence of this condition. 7. It may be well to contrast the infectious character of the feces with that possessed by the urine, for in many points the two are dissimilar. In the first place, it must be noticed that whereas the feces contain the typhoid bacilli in apparently every case this does not obtain with the urine. Probably, indeed, in no more than 25 per cent. of all typhoid cases does the urine possess this dangerous early stage—within the first three weeks. However, only becomes dangerous towards the end of the typhoid but very rarely, if ever, do they contain such quantities as may be present in the urine.

[illegible][illegible]

and finally disappeared with the pus. Probably, therefore, the urine contained typhoid bacilli for about three weeks.

The case is of interest, then, in showing how enormous may be the number of typhoid bacilli in the urine. It also shows that though pyuria in typhoid fever is generally due to infection by bacillus coli communis, yet it may be brought

FIG 2

A drop of the urine in Case 3 passed on Dec. 6th—i.e. two days after the temperature had fallen to normal for good dried on a coverglass and stained with gentian violet. The urine was obtained immediately after it had been passed and the preparation was at once made. Many clumps of typhoid bacilli are still seen but only a few pus cells. (Photographed by Dr Norman $\times 350$)

about through the agency of the typhoid bacillus itself, as indeed it was in one of Blumer's cases.²⁶ It may be noticed, also, in connexion with this case that the stools were examined on four occasions during the pyuria—and in each case with a negative result—that is to say, while the urine was swarming with typhoid bacilli none could be obtained from

FIG 3

Also from the urine of Dec. 6th from the same specimen as Fig 2. A clump of typhoid bacilli is shown under a higher power. The rod-shaped bacilli are well seen. (Photographed by Dr Norman $\times 1000$.)

the stools (at this later stage of the disease). The importance of collecting the stools uncontaminated by urine is thus emphasised. It is important also to note that the blood was examined for the presence of typhoid bacilli on Dec 3rd

and Dec 6th, but on each occasion with a negative result. This tends strongly to show that the very copious excretion of typhoid bacilli in the urine in these cases must be due to some local change in the urinary tract and not to a filtration of bacilli from the blood.

It will be instructive now to add together all the most recent observations made on typhoid urines, so that by a general survey of a larger number of cases we may find out in what proportion of cases and under what conditions the bacilli occur in the urine.

1 *In what proportion of cases does the condition occur?*—To answer this question we have the following observations—

TABLE II

	Number of cases observed.	Positive results obtained.	Negative results.
Richardson	33	9	29
Horton Smith	12	4	8
Blumer	10	2	8
Total	60	15	45

Thus typhoid bacilli have been observed at some period of the disease in the urine in 15 out of 60 cases, or in just 25 per cent of cases.

2 *How often may we expect the urine to contain the bacilli in such enormous quantities as to render it turbid?*—In this connexion we have the following data—

Petruchsky	out of 50 cases found it in 3
Horton Smith	12
Blumer	10
	72
	5

(Richardson does not refer to the point in his paper.)

Thus out of 72 cases examined this condition has been present in five, giving a percentage of seven for all cases of typhoid fever, or if we assume that it never occurred in any of Richardson's 39 cases (since he does not refer to the matter at all) we get a total of 111 cases examined with five positive results, giving a percentage of 4.5. It is probable, therefore, that we shall not be far wrong if we assume that this very serious complication occurs in about 5 per cent of all typhoid cases.

3 *Date of the first appearance of the bacilli.*—In nine of the 15 positive cases recorded above the date of the first appearance of the bacilli was determined with accuracy. This occurred on the fifteenth day (twice), on the twenty-fourth, thirty-second, thirty-sixth, and thirty-ninth days (once each), and also on the fifth, sixth, and tenth days of the disease after final defervescence—that is to say, it always first occurs late in the disease and has not as yet been observed earlier than the fifteenth day.

4 *Duration of the phenomenon.*—With regard to the length of time during which the bacilli may persist in the urine if no treatment be adopted and if the patient survive we have the following facts. Of 10 such cases recorded the duration of the bacilluria has been in each respectively—8 days, 21 days, 25 days, 30 days, 70 days, and +13 days, +18 days, +19 days, +34 days, and +40 days (the + in the latter five cases signifying that the patients still continued to excrete bacilli when the observations were discontinued). It may therefore be said that while the duration may vary within somewhat wide limits, the excretion of the bacilli usually lasts for some considerable time, extending often far into convalescence. Indeed, so prolonged may the condition be that several of the patients have actually been discharged from the hospital still exhibiting the phenomenon. Very rarely also the condition may apparently persist for months or even years.²⁷

5 *The character of the urine.*—It might reasonably be expected that when the typhoid bacilli occur in the urine this excretion would be altered in some definite and uniform manner and that thereby our attention would be drawn to this dangerous condition. Unfortunately this is not the case—apart, that is to say, from that occasional general turbidity referred to above which, if not due to phosphates, should always lead to a microscopic, and

ACUTE INFLAMMATION OF THE AORTA ASSOCIATED WITH PROFOUND MYOCARDIAL DISEASE

By F J POYNTON, M.D. LOND.,
CASUALTY PHYSICIAN TO ST MARY'S HOSPITAL.

CASES are recorded from time to time in which, with or without angina, death occurs quite suddenly and in which the necropsy reveals a condition of inflammation at the base of the aorta unusually acute in its character and remarkably localised in its distribution. In these cases the aortic valves may be thickened by chronic inflammation and yet they may nevertheless be quite competent, and neither during life nor after death can aortic regurgitation be demonstrated and brought forward as an explanation of the sudden cardiac failure. The area of the aorta which is so gravely and severely diseased is the one from which the coronary vessels arise, and it is a natural suggestion that the heart wall has suffered in its nutrition either from a narrowing of the lumen of one or both of these arteries, or that the vessels have shared in the same acute process, and their ramifications have become occluded as a result. A reference to the literature upon this subject proves that such may be the case in some instances, but in the two cases which are recorded below I do not think that such an explanation is tenable. In neither of these two cases were the orifices of the coronary vessels certainly diminished in size nor were their walls visibly diseased, and microscopic examination of the heart wall showed that their ramifications were not occluded. In both cases the cardiac wall was examined with especial care and in both the changes found were widespread and severe and of a nature analogous to that found in the aorta. It is difficult to escape from the conviction that there had been a common antecedent cause which had thus injured these two organs which anatomically and physiologically are so closely associated. The changes in the aorta were obtrusive and in the first of the recorded cases those in the heart wall might macroscopically have been easily overlooked, yet in both cases I should suppose the sudden death depended far more upon these less obtrusive signs in the heart than they did upon the striking changes in the vessel wall. The question of the etiology of this condition is one of great difficulty and it will perhaps be the most rational course to record the two cases with the necropsies and microscopy before allusion is made to their causation. I am indebted to Dr Cheadle for the first case, under whose care the patient had been while in St Mary's Hospital.

CASE 1.—A married woman, aged 38 years, was admitted to St Mary's Hospital under the care of Dr Cheadle on Feb 8th, 1899, suffering from pain in the region of the heart and vomiting. Two months before Christmas she had first noticed occasional attacks of precordial pain extending down the left arm which she said became blue and useless. These attacks, infrequent at first, had during the last week become frequent and severe and were accompanied by vomiting and faintness. Except for a severe attack of "influenza" four years before, from which she completely recovered, her health had been good. She had one healthy child and there had not been any miscarriages. She was said to have been addicted to alcoholism and to have been maltreated by her husband. Her father was still alive, aged 78 years, and her mother died in childbirth. The patient was well nourished and on admission was quite comfortable and free from pain, but shortly after reaching the ward she had a slight attack of pain in the chest and left arm with a feeling of faintness. Dr Cheadle saw her during this attack and considered it to be one of true angina. The next day she was quite free from pain and she then volunteered the statement that any sudden exertion, even sitting up in bed, was liable to bring on the pain. The temperature was normal. The pulse was of low tension with a small wave, it varied in rate considerably, but was about 72 when the clinical notes were taken. At times it was excited and irregular. The cardiac pulse was in the fifth space internal to the nipple line and the area of dullness was slightly increased to the left. The first sound at the apex was sharp and was preceded occasionally by a short presystolic murmur. The

second sound was reduplicated both at the apex and the base. The second sound at the base was sharp and there was no suspicion of a diastolic murmur. The urine was natural, of specific gravity 1025, and there was no evidence of disease in the other organs. The whole of this day and the following were passed in comfort, but at midnight on the 11th a severe anginal attack commenced. The pain radiated over the precordial region, between the shoulders and down the left arm, and was accompanied by severe vomiting. The face became deathly pale and the extremities cold and clammy. The pulse was rapid and irregular and the first sound reduplicated over the whole precordial area. The patient was in great distress and complained of vertigo and loss of vision. This condition, in spite of every attempt at relief, continued with remissions and exacerbations until 3 A.M. when the patient died. For the account of the anginal attack and the major part of the clinical notes I am indebted to Dr Sumner, house physician, and to Dr Cheadle.

The necropsy was made 32 hours after death. The pericardium was natural and the heart itself was slightly dilated. The cavities were empty and the large veins were gorged with blood. There was a white patch upon the right ventricle and the cardiac muscle was pale and pink in colour. The aortic valves were distinctly thickened but quite competent. The pulmonary valves were natural. The mitral valve was affected by a chronic valvulitis which had slightly narrowed the orifice. The posterior flap had been most affected and the chordæ tendineæ in one part were so shortened that at this spot the valve was tethered on to the papillary muscle. In the substance of the valve there was a calcareous nodule. The tricuspid orifice and valve were natural. Neither ventricle was hypertrophied. The left auricle was slightly thickened. The commencement of the aorta for the first two inches was extensively diseased and this condition extended in irregular patches along the arch. The intima of the vessel in this situation was raised from the general surface and was pinkish red in colour, where the disease was most acute. Some of these raised patches had a translucent appearance, others were yellow with a red flush around their bases. A few patches resembled the ordinary condition of atheroma. The appearance was that of an acute aortitis supervening upon a more chronic inflammation. The large vessels springing from the aorta were not affected. The orifice of the right coronary artery appeared narrower than usual, but it admitted a large probe easily, and the walls of both vessels were macroscopically healthy. The other large arteries were not diseased. There were peritoneal adhesions the result of a previous inflammation between the left lobe of the liver and the spleen, and in the midst of these adhesions there was a calcareous nodule of the size of a large marble. Except for this peritonitis there was no evidence in the other viscera of lesions which might have been explained by syphilis. The bones were only examined by palpation, but no results of a localised chronic inflammation were detected in any of them. The kidneys macroscopically and microscopically were healthy.

Microscopy of the aorta and cardiac muscle.—The sections of the aorta were made from tissue fixed in corrosive sublimate and embedded in paraffin. The intima was swollen and the vessels were distended. Around the vessels there was a free exudation of cells and the fibrous tissues were swollen. In places the cell exudate reached the surface of the intima. The elastic coat was also freely infiltrated with leucocytes which extended to some depth into its substance. Where the aorta merged into the heart wall itself the exudation could be traced beneath the endocardium of the left ventricle.

The cardiac wall.—Both the left and the right ventricle were examined, the former in three different places and the latter in two. Some of the material was fixed in sublimate and some in Hermann's fluid. All the sections were cut in paraffin. Extensive changes were found in both ventricles which, speaking generally, consisted of scattered foci of advanced disease surrounded by areas comparatively unaffected. The morbid changes are considered under the following headings: (1) the nuclear changes, (2) the changes in the muscle protoplasm, (3) the changes in the interstitial tissues, and (4) the changes in the vessels.

1. *Changes in the nuclei.*—The nuclei stained with carbol-thionin took the dye but feebly as compared with the muscle protoplasm, which was coloured a deep blue, whereas in

Case 1.—The patient, a married woman, aged 33 years, recovered. She began her work as a laundress at the age of 16, and was very busy and worked hard. She began to feel ill at the age of 18, and was very nervous and had a great deal of trouble in her head. She began to feel ill at the age of 18, and was very nervous and had a great deal of trouble in her head. She began to feel ill at the age of 18, and was very nervous and had a great deal of trouble in her head.

[illegible]

but she never thoroughly recovered and has now completely relapsed. A like disappointing result was met with in a case of acute mania. The other cases treated did not show even a temporary improvement.

Hatton

AFTER-PROGRESS AND TREATMENT OF TWO CASES OF GASTRO-ENTEROSTOMY

BY RICHARD BEVAN, L.R.O.P. LOND.,
M.R.C.S. ENG., D.P.H.

IN THE LANCET of Sept. 26th, 1896, under the heading of "A Plea for Early Operation in Dilated Stomach due to Pyloric or Duodenal Obstruction" I gave the history of two cases of dilated stomach and the ultimate benefits derived from the operation of anterior gastro-enterostomy. One case was that of a probably catarrhsed duodenal ulcer, the other a non-malignant pyloric tumour. In the first a Murphy's button was used, in the other direct suture. In the course of my paper, with a view to accentuate the necessity of the more early resort to operative interference, I described the sufferings and drawbacks consequent on the postponement of operative measures, and I suggested that this temporising or prolongation of medical in substitution of surgical treatment might be due either to an exaggerated view of the seriousness of an abdominal operation, or to not sufficiently grasping the serious nature of the destructive agencies at work on the organ and its glands by delay, or to anxiety to take advantage of the slightest fancied improvement (often quite temporary) obtained by lavage, dieting, anti-fermentatives, and medicines, or perhaps to an unwillingness to assume the responsibility of recommending such an operation in cases where there are difficulties in the accurate diagnosis of the cause of the dilatation where there is no lump, or to recommend it at all where the presence of a lump at the pylorus makes the result unpromising. Since my paper was written the fallacy of these arguments has been demonstrated by the wonderful success which has attended abdominal operations generally in the hands of competent surgeons and, amongst others, operations on the stomach itself—gastro-enterostomy most of all. Again, purely malignant cases seen and recognised early and operated on quickly have not suffered half the drawbacks of the non-malignant cases which were under prolonged observation and allowed to drift into the exhausted, poisoned, wasted, half-dead state before operation which is so prejudicial to the patient and operator. And, lastly, it has been proved that many lumps apparently malignant have by the recovery of the patient proved to be innocent and thus have been suitable cases for operation. A reader of the medical journals of to-day will perceive that the hesitation of former days has changed since 1896 and perhaps in some degree gone to the other extreme, the operation being performed by Tuffier of Paris for the sake of the rest it gives to simple ulcer of the stomach, yet it must be acknowledged that the operation has had a successful career in the hands of many surgeons and its earlier adoption has lessened the risks incident to the operation, given the patient a better start on the road to recovery, and lessened his drawbacks in the years to come. I pointed out in my paper that the evil results of this delay were destruction or atrophy of the digestive glands of the stomach, enormous over-distension and dilatation of the stomach walls, thickening of portions of the coats by fibroid induration or degeneration of the submucous coats leading to weakened contractile power, inability to expel the contents of the stomach, stagnation of food and consequential formation of a fermenting residuum with the evolution of disgusting gases, distress, discomfort, loss of sleep, and vomiting. I finally pointed out that the operation gave almost immediate relief to the more urgent symptoms of obstruction, but that the other conditions would take years to overcome and remedy.

It is now three and a half and three and a quarter years since the operations. I have therefore thought that it might be of interest to describe the progress of these cases and the means adopted during the interval to combat and alleviate the various symptoms, hoping that the hints may be of service to other practitioners in dealing with similar cases. In both of my patients the operation performed was anterior

gastro-enterostomy. Owing, however, to certain drawbacks attendant on this operation I regretted for a month at least that the posterior operation was not chosen. However, I suppose each has its advantages and disadvantages—for instance, in the anterior operation with a Murphy's button the whole time consumed is about from 20 to 25 minutes, which is an important detail to a patient reduced to a skeleton and with no surplus strength, there is, again, less manipulation and the operation is easier to perform. There is this disadvantage, however, that when the patient is in bed after the operation and lying on his back there is a tendency for the bile to flow into the stomach, for it will be seen that the aperture of junction is situated in what in this position is the floor of the channel along which it flows. This, most operators have found, disturbs digestion, fills out the stomach with irritating fluid, resulting unless removed by syphonage in vomiting. This annoyance continues for months after the operation in a greater or less degree and of itself compels recourse to the syphon tube. It has been suggested that the bile does not flow through the operation hole but back through the disused pylorus. I think this the most unlikely explanation, for the pylorus is always on the watch against reflux of food or liquid, and in the cramps and spasmodic contraction in addition to deal with. Then, again, with the anterior operation the food while the patient is recumbent has to be expelled through a trap door in the roof of the cavity with the upper wall of the gut acting as a valve flap. It is argued that this fact does not interfere with the free expulsion of the food from the stomach owing to the free contractions of the walls of the cavity, but it certainly did in one of my cases, for in the dilated condition of the stomach this very necessary contractile power is absent and the walls are acting at a mechanical disadvantage. I therefore advised my patient never, if possible, to have a meal when about to retire and never to lie down immediately after a meal, the upright position and some movement helping, in my opinion, to allow of a more ready discharge of the food through the aperture. Again, I used to advise my patient when in bed to help the natural expulsive efforts by turning over on to the right side almost on to his abdomen, thus allowing the gut to become the most dependent part. I advised, too, his kneading and gently rubbing the stomach in the direction of the aperture into the bowel. How far these manoeuvres were successful and how far contractile power was returning to the wall of the stomach could only be tested by the condition of the morning wash-out to which I will allude later.

Returning to the merits and demerits of the posterior operation it will be plain that in the recumbent position it allows of the speedy emptying or draining of the stomach contents into the bowel (its remaining in the stomach we know from the effect of recent operations being quite unnecessary to fulfilling the requirements of the nutrition of the body), and consequently the stomach has more rest and there is less chance of the stagnation of the food, in fact, theoretically it is the more preferable operation, but I apprehend that the drawbacks are mainly "operative"—that is, that it takes about two hours to complete, and that the operator is pretty well limited to a gastro-duodenostomy instead of a gastro-jejunostomy. Making a hole in the transverse mesocolon, which is highly vascular, increases the risk, besides which, dragging a portion of jejunum through it would tend to open up the risk of kinking and subsequent dangerous obstruction. This gastro-duodenostomy, then, although theoretically the more perfect operation, has the disadvantages of being lengthy and difficult, in themselves serious drawbacks, and it might not always be convenient to choose a bit of intestine so close to the stomach in certain cases, so the anterior operation is the one most likely to be chosen by operators notwithstanding any disparagements which may be made to its adoption.

Much misconception seems to exist in different cases as to the extent of the dilatation which there is both before and after operation—at least, such was the case in more than one of my cases. For instance, one case was seen by three eminent consultants and pronounced slight in extent owing to having been seen early in the morning after a very slight meal, when I am sure that at certain times of the day the greater curvature almost reached the symphysis pubis. This in certain cases may have a disastrous influence on an opinion as to the future treatment or on the recommendation of

[illegible][illegible]

with secretion of ropy mucus, I recommended a weak carbonate of soda solution and I believe that it had a good effect.

It may appear to be a small matter, but I am bound to lay stress upon the necessity of thoroughly cleaning the tube inside and outside on each occasion of use. It should be thoroughly washed, some disinfectant solution should be passed through it, and it should be allowed to lie for a time in some Condy's or Sanitas solution after use, for I am certain that I have seen re-inoculation of sarcinae at the next introduction into the stomach by the neglect of this precaution.

Next with regard to the value of the various antiseptics, or rather anti fermentatives, which are recommended in all stages of this complaint, I must confess that my experience of their use has been most disappointing. I found that to have any anti fermentative action they had to be taken in such doses as almost to become irritants and that unless taken almost before fermentation set in they were practically useless and even then they delayed or inhibited digestion. I found that once decided fermentation had set in in a meal nothing short of washing out gave relief, if allowed to remain scalding, eructations, and eventually gastric catarrh and vomiting resulted. I found, therefore, that it was essential in my endeavour to assist digestion to prevent catarrh, and that in order to do this an attack of fermentation had to be nipped in the bud. Sometimes patients were apt to take liberties and to indulge in things which proved to be indigestible, with resulting fermentation and discomfort, then no antiseptic was of use and lavage was imperative. This had to take place occasionally at irregular times, such as in the night. On the other hand, I have known times when a patient has dined out, not too wisely either, fully prepared to put up with the consequences, and yet to his surprise has been none the worse for it. Among the antiseptics in more frequent use I have tried creosote in pill, capsule, and palatinoid, carbolic acid, soda sulpho-carbolate, charcoal, sodic sulphite, soda salicylate, and salicylic acid. This last in five grain doses in cachets appeared to be the only one upon which any reliance could be placed.

With regard to diet the meals should be moderate in amount and comparatively dry, with the avoidance of anything which might form a suitable cultivation soil for germs. One patient tried the drinking of hot water half an hour before meals but its effects appeared disastrous as very little of it was absorbed by the time the meal was taken. Liquids should be taken at the end of the meal and be limited in quantity and some hot water should be taken at bedtime to replenish the system. Milk and farinaceous puddings I found to be a ready source of fermentation, and strong tea as a drink and afternoon tea as a meal undesirable. The following dietary answered very well. Breakfast at 8.30 A.M., to consist of fish, eggs, or tongue, toast or stale bread, butter, and some very weak China tea. Lunch at 1 o'clock, to consist of either fish, fowl, sweetbread, brains, or calf's head bread or toast, biscuits and butter a tablespoonful of whisky or brandy with six ounces of plain water at the end of the meal, and no vegetables. Dinner at 7 or 7.30 P.M., to consist of either stewed chop or stewed pigeon, steamed fish, poached eggs, and possibly a little milky rice pudding, biscuits and butter, brandy or whisky and water as at lunch, no vegetables, and no fruit. Occasionally a glass or two of madeira might be substituted for the whisky. At bedtime a tumbler of boiling water was to be sipped. Shortly after the operation my patient found great benefit from an ounce of raw meat juice at 11 A.M. and another at 4 P.M. Wyeth's or Valentine's extract might be substituted, but personally I favour the home-made article, for the manufacture of which I found an old tincture press far and away the most convenient article. Later, when my patient is improving, digestion is increasing, and washing out is being gradually omitted, I substitute a tumbler of boiling water at 7.30 A.M. containing either 15 grains of salicylate of soda or one drachm of sulphate of soda. Then the dietary can be enlarged so as to allow for breakfast some toasted bacon or a poached egg or some cold boiled bacon fish (boiled or steamed), and omelette or scrambled eggs, at 11 A.M. a glass of port wine, at 1 P.M. lunch of practically the same food as above or increased by the addition of lamb, boiled or roast mutton, e, baked apples, stewed rhubarb and spinach which has

been passed through a sieve. Dinner as above, with the addition of blanc-mange or rice with fruit jellies and currant or apple, &c., to taste. In the afternoon later a little milk and a biscuit or madeira cake may be substituted for the meat-juice, but tea (afternoon tea) delays digestion and cannot be recommended. At 11 P.M. the patient should take his boiling water. Vegetables are in some forms indigestible and in others conduce to fermentation, salads, oranges, grapes and apples, and most fruits are distinctly bad, so also are milk in any quantity, sugar, and farina either alone or in combination—all conducing to active fermentation. Experience enabled one of my patients to explode a popular fallacy—viz., that cold meat was indigestible, in fact, he came to quite the opposite conclusion, whether it was that it was drier or why I do not know. Hashes and minces except of fresh meat were abominations. Gravies, sauces, pickles, curries, and stews are inadmissible.

I found that digestion in this, as in other diseases of the stomach, was much influenced by exhausting work and anxiety, in fact, so much did defective innervation cause delayed digestion and all its troublesome sequels that two years ago after a period of great overwork a consultant whom one of my patients saw thought that the aperture was contracting but recommended before an exploratory operation his trying a change to Switzerland. The bracing air and change acted like a charm—the gastric secretions and movements necessary for healthy digestion were restored and the patient returned to work with renewed vigour. My patients did not try many drugs, they were nitro muriatic acid, hydrochloric acid phosphates, nuxvomica and strychnine, bismuth alkalies and cascara. I think they derived most benefit from a pill containing at first a quarter of a grain of extract of nuxvomica three times a day and increased later to half a grain. To combat the constipation I tried a soap-and-water enemata every morning, then I substituted the soda sulphate in the hot water in the morning and later still relied on cascara. This has to be continued even now. I always provided an emergency draught containing soda sulpho-carbolate, aromatic spirit of ammonia, tincture of nuxvomica, and peppermint water for relieving the distress at night caused to the patient by the upward distension of the stomach against the diaphragm and heart. Sitting up in bed, friction of the stomach, and a dose of this mixture in most cases quickly gave relief. With regard to artificial digestives, such as pepsin (liquid and solid), papain, and lactopepsin, they appeared utterly useless. One patient, however, expressed some belief in Kepler's extract of malt.

To sum up the results of the operation, I think that without exaggeration it may be said that in each case the life of a patient has been saved who at this period of time could not possibly have been living without it, since then with improved nutrition the circulation has improved, fainting and toxemia have disappeared, the earthy complexions have improved, and sound sleep has returned. The Murphy's button has not been passed, but no discomfort has been experienced. With regard to the present condition of the two patients after three and a half and three and a quarter years both are well and at work. In Case 2 the weight is normal and in Case 1 it is about a stone under the normal. Digestion has continued to improve in both although in Case 1 (the more severe case) a little care has still to be exercised in the articles of diet, but with the other anything that comes to table does not disagree. The lump, which was most probably inflammatory thickening, has disappeared. In Case 1 the stomach is still dilated and splashing can be obtained, but both symptoms are improving. The thirst, which perhaps was one of the most distressing symptoms of all, has disappeared with the increasing improvement in the digestive functions of the stomach. By the way, this did not appear to depend upon a desire for liquid but upon irritation of the mucous membrane of the stomach and to be reflex in character, although the throat was dry and parched, it was the dryness produced by a hot pipe or cigarette. Finally, I cannot better conclude than by quoting a letter which I received from one of my patients—viz. "I am happy to say that to all intents and purposes I am quite well, up to my usual weight, 10 st. 7 lb., and am working up to my usual form and can eat anything I come across in reasonable form. To-day is the anniversary of my operation. I am really almost overwhelmed when I think of the wonderful change wrought in my health with my deep debt of gratitude to my God who so mercifully has aided the skill of the surgeon and practically made a new man of me again." May I express the hope that, aided by improved means of diagnosis,

of the help of confidence obtained by increased experience and by the reports of successful cases operators may go on at after year giving cause for more patients to reach the sentiments of the one quoted above.

AFLECTION OF TUBERCLE FROM SONG- BIRDS A FERTILE THOUGH UN- SUSPECTED SOURCE OF PHTHISIS

BY A TUCKER WISE, M D BAVT, M.R.O.S E.N.G.,
L.R.C.P LOND, DIPLOME SUISSE FÉDÉRAL

WHENST engaged on an inquiry into the sources of acillary infection in cases which have recently come under my notice I have been struck by the number of patients who have lived in contact with diseased canaries and other feathered pals Among cage-birds, pigeons, and poultry tuberculosis is a common disease and there is a strong probability that avian infection can be conveyed to human beings who keep birds within the house The objectionable practice of allowing them to place their beaks in contact with the lips is a risky and dangerous proceeding as regards ability to receive bacilli in this way if the bird is not healthy Birds can also convey filth and with it disease germs from the cage to human food, or the dust of dried excrement and mucus may pollute the air of any room in which birds are kept Feeding and nursing sick birds and blowing the dust and husks from their seed and cleaning the cage are not without danger In my opinion the canary or any other bird kept in the kitchen is a positive peril to the household, as by fluttering and whisking the dust from its beak or mucus from its beak the food of a whole family can be contaminated

Parrots also can be attacked by tubercle, which is characterized frequently by new growths of horny skin which sometimes attain a considerable size They can be easily broken off and they contain numerous tubercle bacilli in their basal granulation tissue Tuberculosis of the lungs and conjunctiva is often met with According to a compilation by Debarthe the skin was affected in 62 per cent, the tongue in 16 per cent, and the bones and articulations in 12 per cent, of all the cases From a dissection of point of view it is important to note that the tubercles of parrots is distinguished by the presence of an enormous number of bacilli Phtisicosis, an infectious disease of parrots, has already been observed to cause a serious and fatal pneumonia of a special type transmitted from these birds to man In 1892 about 50 miller epidemics have been noticed and studied by Gilibert, Fournier and Debove At the same time Nicard was fortunate enough to isolate a short, thick bacillus with rounded ends and he gave a description of it before the Council d Hygiene in 1893 Cadot contributed a paper on the tuberculosis of the smaller animals and pointed out that dogs and cats were much more liable to tubercle than was generally supposed Tuberculous dogs spread infection by nasal discharge, by excrement by urine, and by lesions of the skin equally in the same manner One of the cats examined had a large ulcerated wound of the nose also noticed external tuberculous lesions as being frequent among parrots

Taking into consideration the unnatural and unhealthy life to which man subjects the domestic animals, especially birds contained in small cages it is not surprising that these captives should become diseased and pollute the air with pathogenic micro-organisms in a work on diseases of cage birds Dr W J Green mentions phthisis as a form of tuberculous infection which is not usually met with in birds except as a sequel to the occurrence of the disease in other parts of the body, notably the liver and spleen, however as a secondary affection it is not uncommon amongst canaries He names the symptoms as gradual emaciation, sometimes a husky cough inability to moult and phthisis and Fehleberger and Frohner Veterinary Pathologist M H Hayes, J R C V S, 1892

Translated by
J. H. Hayes, J. R. C. V. S., 1892
Revue de Médecine Vétérinaire 1892

lastly diarrhoea, and adds that canaries are the most frequent victims, but that fowls, pigeons, and pigeons also suffer from the disease Bacchman defines a disease of cage birds called the "pip" as a catarrh or cold by which the nostrils are stopped up and the membrane covering the tongue is hardened by inflammation No bacteriological observations have yet been made on this catarrhal disease so far as I know, nor can anyone say whether it is contagious or the reverse There are also forms of tuberculous tendency in cage birds termed "rickets" and "scrofula" In mentioning the latter Dr Green says that it is strongly hereditary, and knowing this the amateur for his own sake should avoid breeding from a tainted stock, which may endure for years, it is true, but will always be unhealthy and unsightly Gilbert, Roger, and Cadot have been able to produce tuberculous in rabbits by inoculating them with the avian bacillus We must therefore admit that avian tuberculosis may occasionally be transmitted to mammals Much incipient unnoted disease exists amongst domestic animals and bacillary affections enter largely into the mortality of cage birds From a clinical inquiry I find and some remarkable coincidences of pulmonary tuberculosis developing in families who have kept birds in the house, and I am of opinion that a number of healthy round individuals contract the disease from this origin An instance of suspected infection arising from poultry where the diseased fowls were consumed as food is given by Dr Peter Paterson in THE LANCET of Oct 30th, 1897 In this case, although the diseased fowls had no access to the dwelling house, Dr Paterson considered that the infection of the family with tuberculous disease (the wife dying ultimately from intestinal and the daughter from pulmonary tuberculosis) was derived either indirectly by handling or swallowing the germs as they were blown about in the poultry house, or more directly by eating the carcases of the birds which may have been insufficiently cooked, from my own personal investigations, already referred to, I will now relate the following examples of infection to canaries and other small cage-birds occurring amongst some of my patients and in their households

CLASS I.—This case occurred in a large, well built house situated in one of the health resorts The family health was good There was no hereditary tendency to tuberculosis either in the parents or grandparents About from 20 to 30 small birds, chiefly canaries, were kept for many years in rooms over the stables, distant about 50 feet from the house Many of these birds were brought in from the dining room and hall In the kitchen a cage hung over the table on which were placed the patty, cake, jelly, ice, &c for meals In 1887 a domestic servant, aged 23 years, always delicate, developed cough with hæmoptysis, in 1889 a domestic servant aged 22 years, became ill with cough and expectoration In 1890 a domestic servant, aged 24 years, developed cough with hæmoptysis In 1890 a daughter in the family aged 30 years, well developed and enjoying good health, whose weight was 9 st 7 lb, and who was fond of out door exercise, was taken ill with hæmoptysis Cessation of the apex of the left lung supervened and a cavity formed which had now cicatrised (1899) In 1892 a son in the family, aged 21 years, always healthy, whose weight was 11 st, and whose height was 5 ft 10 in, was taken ill with hæmoptysis the apex of the right lung After two winters' treatment in the Alps no physical signs of disease remained In 1893 a son in the family, aged 27 years, athletic strongly built, and healthy was taken with hæmoptysis, cough, and loss of flesh Rapid and extensive tuberculous infiltration of the lungs supervened and he died in 1895 This patient kept birds in his bedroom In 1893 a domestic servant, aged 25 years, was taken ill with cough and expectoration followed by hæmoptysis In 1896 a daughter in the family, aged 35 years, had hæmoptysis and cessation of the apex of the left lung with formation of cavity She is still under treatment

CLASS 2.—This case occurred in a house situated in a large town The patient, a man, aged 47 years who had a large been in good health and with no family history of tubercle, suddenly broke down with cough, expectoration, and loss of flesh He regained a loss of 20 lb in weight during one winter in the Alps A cavity which formed in the right apex cicatrised after three years' treatment and the patient now lives in the Alps

3 Brit. Med. Jour., March 5th 1893

enjoys good health. He kept a canary which died before he broke down in health.

CASE 3—This patient was a medical man, aged 31 years, practising in a health resort. He was a well built, athletic man and had always been in the enjoyment of good health. There was no family history of tubercle. Illness commenced with hæmoptysis during influenza. There was dulness at the apex of one lung with a few fine crepitations and expectoration containing half a dozen tubercle bacilli in a field. There was loss of weight to the extent of 21 lb. This patient recovered completely after one winter in the Alps. He weighs now 13 st. His height is 5 ft 9 in. He writes "We had two birds and strange to say they both died about the time of my illness."

CASE 4—The patient was a dental surgeon, aged 43 years. There was no family history of tubercle. He was well nourished and was in good health up to two years ago. His weight then was 13 st. and his height was 5 ft 11 in. After a small hæmoptysis cough and expectoration supervened with bacilli in the sputum. Canaries were kept in the house but none died, nor did any of the birds appear to be diseased. This patient is still under treatment.

CASE 5—The patient was a woman, aged 20 years. She lived in a healthy part of Queensland, Australia. She was taken ill with cough, feverishness, expectoration, and emaciation. Riles were detected throughout both lungs, but very few bacilli were observed. There was no family history of tubercle either in the parents or grandparents. From 15 to 20 canaries were kept in an aviary on the balcony of the house, several of these birds died from time to time. A brother had died from phthisis, aged 25 years. Another brother, aged 23 years, and a sister, aged 20 years, had died from phthisis. The patient named above died after one year's illness. All these persons had been in contact with the birds for some years.

CASE 6—A family living in a healthy situation in Silesia kept a large number of birds in an aviary fitted with artificial trees, water, &c., in the conservatory. There was no hereditary taint of tubercle with the grandparents who died at advanced ages—viz. the maternal grandmother, aged 89 years, from heart disease, the paternal grandfather, aged 70 years, from gout, the paternal grandmother, aged 75 years, and the paternal grandfather, aged 75 or 80 years, from disease not known but it was not lung disease. The family inhabiting the house died as follows: the mother, aged 61 years, from pulmonary consumption of three years' duration, the father, aged 57 years, from pulmonary consumption of six months' duration. Nine sons and daughters also died from phthisis at the following ages: 12 years, 14 years, 16 years, 17 years, 19 years, 24 years, 30 years, 36 years, and 37 years. Two daughters remain alive, aged about 50 and 60 years, both are affected with pulmonary tubercle in the quiescent condition.

CASE 7—The patient was a youth, aged 18 years. He had had hæmoptysis yearly since 12 years of age. A cavity had formed in the right apex. Several canaries were kept in the house previously to the first hæmoptysis. During the holidays he would have the birds in his bedroom. They were considered to be "unlucky" in bird keeping as so many died.

CASE 8—The patient was a woman aged 33 years. Illness commenced with cough, expectoration, and loss of flesh about two years ago. There was now excavation at the apex of the right lung. There was no family history of tubercle and the patient occupied a spacious house in a healthy situation in London. She frequently visited a house where canaries were kept in the bedroom, dining room, hall, and kitchen. The smell of the cages often made her feel sick. There were two members in the family she visited—husband and wife—but no children. The husband mentioned developed pulmonary disease at the age of 40 or 45 years, although he was considered a strong man and had been an athlete at Oxford.

CASE 9—A woman, aged 22 years, was taken ill in June, 1892, with a cough. Hæmoptysis occurred in 1893. There was no loss of flesh, feverishness, or shortness of breath. A winter spent in Egypt did not prove beneficial. She preferred cold climates. A cavity formed in the right apex without much constitutional disturbance. A linnet and a canary were kept in the house before her illness, she frequently kissed the bird of which died from a wasting disease.

CASE 10—A woman, aged 41 years. She had two or three years in 1896 and feverish symptoms.

supervened. She lost a little weight in the summer, but regained the loss during the cool weather of the autumn. There was scattered tuberculous mischief in the upper portions of both lungs, but with patience and care the disease has become comparatively quiescent. A canary was kept in the dressing room for four or five years. The bird died.

As there is generally a high mortality amongst cage-birds, especially if several are kept together, and tuberculous being very frequent with them, the birds which become affected can doubtless spread bacilli during the course of the disease. It appears therefore inevitable that any person inhaling the contaminated dust of the house runs a decided risk of becoming infected by a respiratory impurity of a virulent nature. On the other hand, tuberculous dust can be deposited on the food of a household, especially on milk, butter, cheese, bread, jellies, pastry, and all cold viands, and in this way convey the avian bacillus to the stomach and intestines. Perhaps the relation of the foregoing cases in which over 30 persons became attacked by tubercle may tend to elicit further information from other observers on the important question of tuberculous infection from avian sources. There have been cases already observed where the avian race have themselves become infected from human sources—e.g., in the case of poultry picking up tuberculous expectoration or eating food previously masticated by tuberculous human beings. It is stated that parrots have taken the disease in this manner and also by the bird inhaling the bacilli of human sputum along with dust deposited in dwelling rooms, mentioned by Friedberger and Fröhner, Hayes, and others. This does not, however, affect the question of the avian race being capable of retransmitting the infection in their turn if kept in a diseased condition in contact with human beings. Although doubts have been expressed regarding the identity of avian tuberculosis with that of mammals, Friedberger and Fröhner mention that the more recent investigations of Cadot, Gilbert, Roger, Fischl, Courmont, and others tend to show that these two forms of tuberculosis are produced by the same species of bacilli, although by different varieties, the differences between them having been produced by differences in their respective modes of nutrition. The number of song birds kept in captivity, especially canaries, must be very large. It is stated by a recent writer in *Good Words*, under the *nom de plume* of "Nightingale," that at a moderate estimate 400,000 canaries are sold every year in Great Britain.

Montreux, Switzerland.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON HERNIA OF THE VERMIFORM APPENDIX.

By W. MCADAM ECOLES, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CITY OF LONDON TRUST SOCIETY AND TO
THE WEST LONDON HOSPITAL, AND DEMONSTRATOR OF OPERATIVE
SURGERY AT ST. BARTHOLOMEW'S HOSPITAL.

IN THE LANCET of May 6th, 1899, two very interesting instances of the vermiform appendix being the sole occupant of a femoral hernial sac are recorded—one having been under the care of Mr. Edmund Owen and the other under the care of Mr. W. H. Battle. One of the most interesting points raised by these cases is the question whether true strangulation of an appendix in a hernial sac ever occurs. By strangulation I would imply the sudden descent of the viscous through a hernial aperture and the immediate nipping of its tissues by the edges of the ring, so that there results an obstruction to the proper return of blood from its vessels. That such may occasionally happen may be true and that it may be in evidence without signs of intestinal obstruction is obvious, for the lumen of the cæcal appendage is not in the direct line of the onward flow of the intestinal contents. But I venture to think that in a large majority of cases where untoward symptoms occur when an appendix is herniated, these are due to inflammatory processes precisely

similar to those which may affect the appendix while still within the abdominal cavity. It is well known that the symptoms of appendicitis may supervene with surprising rapidity, and this fact applied to inflammation within a strangulation had occurred in many cases where an appendix has been found in a hernial sac, apart from other observations have been noted, showing evidence of past inflammation action even if this has been but slight. Again, contractions and foreign bodies within the appendix have been recorded when this organ has been found outside the abdomen. No doubt when inflammation is in evidence the appendix becomes greatly thickened and its tissues will thereby be considerably pressed upon by the fibrous structures around the neck of the sac, but this is a secondary effect and should not be designated primary strangulation. The appendix has been found alone in the sac of a right inguinal, a right femoral and a left inguinal hernia, but I do not know of any instance where it has descended into and remained the only occupant of a left femoral, an umbilical, or a ventral hernia. It has been discovered at all ages, and out of 29 cases which I collected in 1898, it lay in the sac of an inguinal hernia in 16 cases and in that of a femoral hernia in 13 instances.

NOTE ON THE COUNTING OF THE WHITE BLOOD CORPUSCLES

By ARTHUR G. FEAR, M.D. CANSTAR, ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL.

Is the counting of the blood-corpuscles it is advisable, as has been pointed out by Sheermann,¹ to use a single preparation for the enumeration of both the red and the white corpuscles. The blood must be diluted with some suitable fluid at least 50 times, otherwise the red corpuscles are so closely crowded that no trustworthy count can be made. In blood thus diluted the white corpuscles, if not in excess of the normal, are few and far between, over the whole area of 400 squares that are ruled on the floor of the cell in the Thomas Zeiss haemocytometer not more than from 12 to 20 white corpuscles are to be seen in the case of normal blood, the number is so small as to afford a quite inadequate basis for the calculation of the total number of white corpuscles in the cubic millimetre of blood. The object of this note is to indicate a simple means of increasing the area available for the purpose of the count. It is by the use of the camera lucida. The most convenient form is the Zeiss-Abbe drawing camera, which is used with the stage of the microscope in a horizontal position—an important matter in dealing with fluid preparations, the image of the field is projected on to a piece of paper or cardboard lying horizontally on the table immediately to the right of the microscope stand. Before making the blood-count the ruled squares on the floor of the haemocytometer cell are brought into focus and with the aid of the drawing camera the outline of as many squares as appear in the field is accurately marked out on the cardboard. At the time of making the count the image of the corpuscles which lie on the unruled part of the cell floor is thrown by means of the camera on to the cardboard and the corpuscles which appear in the count square are enumerated and included in the count. In practice it is convenient to use a mechanical stage, and with the help of this it is possible to map out with great accuracy as much of the floor of the cell as is occupied by the drop of diluted blood and to enumerate the white corpuscles lying thereon. In this way notice for the purpose of the count is multiplied many times. It is of course essential that the eye-piece should be under the lens during the count should be the same as on the occasion of marking out the squares on the cardboard. For the dilution of the blood I know of no better fluid than that recommended by Sheermann,² consisting of distilled water, 300.0 cubic centimetres, sodium chloride, 1.2 grammes.

¹ St. Bartholomew's Hospital Report, Loc. cit., p. 5-105.
² Proceedings of the Royal Society, vol. 11, p. 5-105.
³ Loc. cit.

Cases of syphilis in which a primary sore is absent are well recognised by competent authorities, but most English surgeons, I believe, are still sceptical on the point. The following case which was under observation from the first is therefore worth recording.

On March 21st a man, aged about 25 years, was sent to me by Dr Steegmann with a view to the diagnosis of syphilis. He had a roseola rash on the chest, abdomen, and hands, but no other signs and no primary sore. In January (two months before) he had contracted gonorrhoea and feared that he had also got syphilis, owing to some inflamed smegma glands exciting his suspicion from that date up to the present time he was under the observation of Dr Steegmann and myself, and at no time did any "primary sore" develop. Later, in March, a typical polymorphous secondary syphilis appeared followed by infection of the fingers and mucous patches on the prepuce. There can, I think, be no doubt that this was a case of syphilis.

NOTE ON A CASE OF SYPHILIS WITH NO PRIMARY SORE

By C. F. MARSHALL, M.D. VICT, F.R.C.S. ENG., CLINICAL ASSISTANT TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS FORMERLY MEDICAL OFFICER LONDON LOCK HOSPITAL, E.C.

neutral potassium oxalate-1.2 grammes, and methylene blue, 0.1 gramme. In this solution the shape and colour of the red corpuscles are preserved. The red corpuscles are not stained and the distinction of the white from the red corpuscles is thus facilitated. For the differential count of the white corpuscles it is desirable to work with an immersion lens and as the depth of the haemocytometer cell renders this impossible it is necessary to prepare a special fluid film. The subject of the differential count was discussed in a paper, to which I would refer, recently read by me at a meeting of the Royal Medical and Chirurgical Society.¹

¹ The Clinical Examination of the Hamulo Leucocytes delivered on April 25th, 1899. La France Medical, August 5th and 13th 1897.

THE HEALTH OF GLOUCESTER.—The report of the medical officer of health (Dr Campbell) for 1898 issued. Dr Campbell estimates the total population of the city at 41,450, an increase of 264 in the year. The births numbered 1315—888 males and 627 females—compared with 1336 in the previous year. The rate is 31.7 per 1000 compared with 32.6 per 1000. There were 694 deaths, as compared with 775—a rate of 16.7, as compared with 17.6 in the previous year. This is regarded as an extremely gratifying fact, as it places the city on a par with the most healthy towns in the kingdom. Dealing with the water supply, the report states that the three sources of supply now available are capable of providing 20 millions per head per day for double the population now supplied. On the whole, the supply generally will, it is stated, compare favourably with that of the best supplied towns and the only fault that can be found is that the Witcombe and Robinhood Hill supplies are not sand filtered as well as decanted and that the Newent supply is not chemically softened.

LONDON HOSPITAL

TWO CASES OF FILARIASIS, ONE EXHIBITING SO CALLED
VARICOSE GROIN GLANDS AND THE OTHER CHYLOUS
HYDROCELE AND LYMPHATIC VARIX OF THE
SPERMATIC CORDS

(Under the care of Mr FREDERIC EVE and Mr J
MC CARTHY, with pathological notes by Mr
H L BARNARD)

THE very important observations made by Mr Barnard in the former of the following two cases throw much light on some obscure points in the life history of the filaria. The fact, however, that in this case the enlargement of the inguinal glands was not due to the dilation resulting from lymphatic obstruction elsewhere does not make it impossible or even improbable that this may be the cause in other cases.

CASE 1 *Enlarged and cystic groin glands on each side ("Demerara groin") due to filaria sanguinis hominis*—

A negro seaman, aged 24 years, was admitted from the receiving room of the London Hospital for tumours in both groins. The patient was a native of Demerara, his father being white and his mother black. Some 12 years ago he fell from a tree among some broken bottles and incised his right groin, soon afterwards the swellings appeared and had slowly and steadily increased. The present appearance of the scar in the right groin would rather lead one to suppose that it originated in a suppurating bubo. The tumours in the groins caused the patient no pain, only inconvenience, and their size was diminished by the recumbent position. On examination it was found that the left tumour was as large as two fists and extended from the anterior superior spine of the ilium to the spine of the pubes, and from Poupart's ligament above to the apex of Scarpa's triangle below. It was flattened (shaped like a bun), was lobulated, and had a pillowy feel like a lipoma. The skin was freely moveable over it and the tumour moved readily on the deep fascia except at the saphenous opening where it was attached. The tumour in the right groin was similar in character but was limited to Scarpa's triangle. The blood was examined at night and the presence of the filarial embryos was demonstrated. They began to appear about 10 P.M. and were most active and abundant at 2 A.M. It was decided to perform an operation and ether having been administered an oblique incision was made by Mr Eve over the tumour in the left groin. On cutting into it chylous fluid escaped. The entire mass was then dissected out and the lymphatic vessels and veins entering the mass were ligatured. All stages of involvement and spongy hypertrophy of the lymph glands were found, from those glands which were not affected at all to those in which the glands had become as large as walnuts, and were composed of a tough, sponge like reticulum filled with lymph. The tumour collapsed when cut into. The swelling in the right groin was then treated in a similar manner. To complete the history of this case the wound healed by first intention and no untoward results had occurred when the man left the hospital a month later.

Examination of the excised glands by Mr BARNARD.—The mass of glands removed was examined two and a half hours after removal by the surgical registrar (Mr Barnard) for filarial embryos. These were found, but were very languid in their movements. This induced him to raise the whole tumour to blood heat. A parent worm was then seen to be wriggling from the cut surface of the mass. This worm was unfortunately broken off at two thirds of its length, but another and complete specimen was obtained from a

fresh cut surface and this worm was safely mounted in glycerine and water and ringed (Fig 1). After again warming the tumour and closely examining the points of reflected light upon its surface, it became obvious that the entire mass was in vermicular movement and it was estimated that at least a dozen parent worms were present in it. It would therefore appear that the hypertrophy of the glands is to be regarded as a result of the direct obstruction and irritation of parent filarial worms living in them and not to lymph congestion due to obstruction of the lymph channels of the abdomen. This observation renders it probable that the distribution of parent worms throughout the body is in some instances much more general than is commonly supposed. If this assumption be correct it explains those cases in which elephantiasis of the leg and lymph scrotum co-exist and in which elephantiasis of the leg follows the removal of a lymph scrotum. It also makes it more easy to understand how the union of the sexes takes place for a male worm to find a single female existing in the body presupposes a degree of instinct and perseverance which is inconceivable. In the Museum of the Royal College of Surgeons of England (No 4029*) is a portion of a lymph scrotum exhibiting a mature female filarial worm projecting from a dilated lymphatic. It was observed by Dr Manson immediately after making the incision. There were no filaria in the blood although they existed in lymph from the scrotum and the groin glands were "varicose." Dr Manson concluded from this circumstance that all the lymph channels were blocked with ova and anticipated finding the parent worm in the scrotum. The parent worm in the present case (see Fig 1) was about three inches in length and resembled a piece of white thread. The microscope revealed a refractive alimentary canal running the entire length of the worm. On either side of this alimentary canal were placed the two uteri. The ova at the deep ends of the uteri were round cells showing no trace of the embryo worms (see Fig 2). As the uteri were traced towards their orifices the ova became more and more formed until at the opening itself free embryo worms were seen in them.

CASE 2 *Chylous hydrocele of the left tunica vaginalis and lymphatic varix of both spermatic cords more marked upon the right side*—This case was admitted to the London Hospital under the care of Mr McCarthy, and Mr Eve and Mr Barnard are indebted to him for permission to publish it with the other case. The patient was a young Scotchman, aged 25 years. He was born in Victoria, Australia, and at the age of 16 years he entered the service of the Eastern Extension Telegraph Company. In the employ of this company he visited Penang, the Straits Settlements, Batavia, Upper Burma, and the north west parts of Australia. On several occasions he suffered from malarial fever. Six years before admission while in Singapore his left testis first began to swell and this he attributed to a bicycle accident. Exercise often made it painful. A little later he began to suffer from periodical attacks of pain in the loins followed by "milky urine," but he never saw blood in the urine. These attacks were apparently due to exercise or exposure to cold. He underwent no treatment for these troubles until six months before admission, when he was in Australia, and a medical man informed him that he had a hydrocele and tapped it. A teacupful of "yellow, cloudy fluid, rather thick in consistency," was drawn off. The patient had recently come to England and as his hydrocele had recurred and a soft swelling had appeared on either side of his scrotum he applied at the London Hospital for treatment. On examination it was found that in the left side of the scrotum there was a hydrocele of about the size of a turkey's egg. It fluctuated and was translucent. On the right side above the testicle was a swelling of the size of a hantam's egg which was soft and felt like a varicocele, it emptied on steady pressure and slowly filled again. Upon the left side a similar condition existed in a minor degree. The patient was very sallow and anæmic. Filarial embryos were found in the patient's blood at night. They were absent from the vessels of the skin during the day and began to appear at from 10 to 12 P.M. Mr McCarthy tapped the hydrocele and drew from it four ounces of chylous fluid. He then injected a drachm of iodine solution. On examining the chylous fluid active filarial embryos were demonstrated. A fortnight later Mr Eve (to whom the case had been transferred) dissected out the lymphatic varix in the right spermatic

* See Museum Catalogue vol. xxiii., p. 265.

frequency in hospital practice the above cases of blastomeres were admitted consecutively into the same bed in the London Hospital. A point of extreme interest about Case I was that on removal the tumour was found to contain a large number of the parent worms of *Stiria baneroffi*, two species of which were secured. Judging from this case it would seem that the name "varicose groin glands" is unfortunate, if the word "varicose" is intended to imply that they result from lymph congestion or are a dilated collateral circulation, the result of obstruction to the main lymph channels of the abdomen. We are indebted to the late horse surgeon, Dr. Spillane, for his careful observations and notes of these cases.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Infections from Unsound Meat—Chemical Composition in Relation to Germinal Action—Exhibition of Specimens—Annual Meeting—Election of Officers—Report of the Committee on Psalido tuberculosis.

A MEETING of this society was held on May 16th, the President, Dr. PARKER, being in the chair.

Dr. H. E. DURNHAM made a communication on infections from Unsound Meat. He had investigated two outbreaks at Surbiton and Balford and had studied the action of the serum from these patients on cultures of various bacteria. As a general result he found that they gave a definite agglutinating reaction in high dilutions with culture of the bacterium *Citrobacter*. This reaction was given with all varieties of this bacterium although there were individual peculiarities in their behaviour. He also added the serum to cultures of typhoid bacilli, but found no reaction unless he used low dilutions of serum. With low dilutions, however, he obtained the agglutinating action. Dr. Durnham pointed out that the serum employed (1 in 10) would give agglutinating reaction with serum from many cases besides those of enteric fever and that it could not be regarded as a specific reaction. For purposes of diagnosis of enteric fever the clinical methods of sero-diagnosis ordinarily followed were quite unreliable, a much higher dilution being necessary. In the cases of meat poisoning to which he referred there was no reaction with high dilutions except to cultures of the bacillus enteritidis. Dr. Durnham thought that there was no doubt that cases of meat poisoning were due to infection by organisms and the reactions he had obtained showed that in his cases the infection was due to the bacillus enteritidis. In most of the epidemics shown by different observers that animals from which the meat came were themselves diseased before death. Lantham slides were shown exhibiting photographs of the clumping reaction, in tubes of cultures, and also micro-photographs showing the polymorphism of the bacillus enteritidis. Dr. WASHBURN was sorry that Dr. Durnham had not gone more fully into the proofs that these cases were always due to an infection and not to absorption. He agreed that in the majority of cases this was so. The old method of removal of alkaloidal promanes from the organs daily hours after death were open to many objections, and it was probable that they did not produce the symptoms met with during life. He was interested to hear what Dr. Durnham had said as to the unreliability of the serum reaction in enteric fever as usually applied, but he thought that in the wards it gave very accurate and useful information.—Mr. A. G. B. GROUTER could not agree that all the evidence was in favour of cases of meat poisoning being infective. The mere presence of the agglutinating reaction did not prove this point, as if a horse were immunised by the inoculation of diphtheria toxin, bacilli being excluded, the blood afterwards gave a good agglutinating reaction with cultures of the diphtheria bacillus. He also quoted Gaertner's other cases in which after the ingestion of large quantities of unsound meat symptoms appeared within three hours which would not be likely with a bacterial infection. In one outbreak which he had investigated the symptoms came on very soon after taking some ham and the severity of the symptoms were proportionate to the amount of meat which the individuals had taken, which was consistent with poison- ing by toxins rather than organisms. Further, there was no

ord, treating it as though it were a varicose. It consisted of dilated and hypertrophied lymphatic vessels with thickened walls. These vessels were held together by loose connective tissue. On dividing them a milky fluid escaped which contained the embryos in active movement. For a few days after the operation the serum was discoloured with an effusion of lymph and at one time it was as large as a

FIG. 1

fatal head. The removal of a few testicles, however, allowed this fluid with some clot to escape and the swelling rapidly subsided, the wound healing without suppuration. The close adhesion of fluid which escaped on removal of the stitches contained dead embryos. When the patient left the hospital a month later his general condition had much improved on a thorough course of treatment with iron and arsenic.

FIG. 2

Unit of worm. Highly magnified.

Hypodermic injections of percolation of mercury were also tried but without any perceptible change in the number of embryos present in the blood. In this case, as in the case, as in the operation followed the operation. Remarkably by Mr. LEY and Mr. BARNARD—By one of those strange coincidences which occur with such astonishing

direct evidence that the bacillus enteritidis had ever been found in the blood of patients during life

Dr JAMES RITCHIE (Oxford) read a paper on Chemical Composition in Relation to Germicidal Action. In his investigations Dr Ritchie employed normal solutions of the various chemical substances investigated and an emulsion of the typhoid bacillus in water, uniform diffusion being obtained by filtering off all clumps by a plug of sterilised glass wool. He investigated groups of metallic salts grouped according to Mendeleeff's law and he found that with metallic salts the toxicity varied with the atomic weight of the base, the acid radical not affecting the result. With the halogens, chlorine, bromine, and iodine the same relation to the atomic weight was observed. With groups of organic bodies in each group the members with the higher molecular weight had the greater germicidal action. There were a few exceptions. Lithium did not take the place which it should among the monatomic group, but it presented also notable chemical differences such as the insolubility of the carbonates. Neither the mineral nor the fatty acids conformed to this rule, but in both cases their germicidal action was proportional to their chemical "avidity."

The following card specimens were exhibited —

Dr A E GARROD Fibrosis of the Lung

Dr W S LAZARUS BARLOW Syphilitic Stricture of the Bile-Duct

Dr H D ROLLESTON Columnar celled Carcinoma of the Tail of the Pancreas

Mr. T LISTER (1) Tuberculous Gastric Ulcer, (2) Ulcerative Colitis, and (3) Ulcer of the Duodenum in elæna Neonatorum

Dr J H DRYSDALE Tuberculosis of the Inferior Vena cava

Dr H A LEDIARD (1) Pin in the Appendix, and (2) Congenital Fibrous Tumour on the Neck of a Child

Subsequently the annual general meeting of the society was held, Dr PAYNE being in the chair. The report of the Council was read and adopted. It announced that an index of the last 13 volumes was being prepared and that the task had been entrusted to Mr Shattock.

A very cordial vote of thanks was given to Dr Payne, who has occupied the chair with great success for the last two years, to the retiring honorary secretary (Mr D'Arcy Power), and to the other retiring officers. The ballot for the election of officers for the season 1899-1900 resulted in the election of the following list — President Mr William Watson Cheyne Vice-Presidents Dr F W Mott, Dr G Newton Pitt, Dr F Charlewood Turner, Dr German Sims Woodhead, Mr Anthony A Bowlby, Mr G H Makins, Mr Alfred Pearce Gould, and Mr Charters J Symonds Treasurer Dr Sidney Coupland Honorary Secretaries Dr Humphry D Rolleston and Mr Charles Alfred Ballance Council Dr John Abercrombie, Dr J Ross Bradford, Dr Sheridan Delépine, Dr James Galloway, Dr Archibald E Garrod, Dr Herbert P Hawkins, Dr R G Hebb, Dr William Hunter, Dr Cyril Ogle, Dr J W Washbourn, Mr William H Battle, Mr Cecil F Beadles, Dr F G Hopkins, Dr H A Lediard, Mr John R Lunn, Professor John McFadyean, Mr D'Arcy Power, Mr J H Targett, Mr Frederick O Wallis, and Mr Edgar Willett.

The committee appointed to consider the nomenclature of the condition sometimes described as "Pseudo tuberculosis" brought up its report. The committee reported that — 1 The term "pseudo-tuberculosis" had been applied to a number of distinct morbid processes which agreed only in the presence of small nodular tubercles. Amongst them were (a) a number of bacterial infections caused by bacilli and cocci of various species, (b) blastomycosis, (c) streptothricosis, (d) aspergillosis, (e) protozoal infection, and (f) pathological conditions arising from the presence of higher animal parasites in the lungs. 2 Confusion had arisen from the employment of the word "tubercle" in two senses (1) as a general anatomical term for a small nodule and (2) in a specific sense for the nodular lesions of the disease produced by the tubercle bacillus of Koch. 3 The word "tubercle" should no longer be used as a general anatomical term but if used at all it should be only as a designation of the nodular lesions produced by the tubercle bacillus. To prevent ambiguity, however, they suggested that all lesions having the form of "tubercles" should be called generally "nodules" or "nodules produced by Koch's bacillus" being distinguished by the nature of the infection, and that the nodules produced by Koch's bacillus should be distinguished by the manner in which they are used if known,

as, for example, "glanders nodule," "aspergillar nodule," or; if their cause was not known, by some distinctive designation not involving any reference to the word "tubercle." They further suggested that the diseases themselves (as distinguished from the lesions produced) should when possible be designated in accordance with the plan indicated in headings (b), (c), and (d), "blastomycosis," &c. The term "pseudo-tuberculosis" would then become superfluous and ought to be discarded altogether. — The report was signed by Dr J F Payne (chairman), Professor John McFadyean, Mr S G Shattock, Dr J W Washbourn, Professor G Sims Woodhead, and Mr A G R Foulerton.

CLINICAL SOCIETY OF LONDON

Right Colotomy for Chronic Colitis — Empyema of the Maxillary Sinus — Pathology and Treatment of Chronic Empyema of the Maxillary Sinus

A MEETING of this society was held on May 12th, the President, Mr LANGTON, being in the chair.

Dr HALE WHITE and Mr GOLDING BIRD contributed a paper on Three Additional Cases of Right Colotomy for Chronic Colitis. The object in all three cases was to give the colon absolute rest. Case 1 — The patient was a woman, aged 35 years, seen with Dr A E Taylor. She had had membranous colitis for 20 years and latterly great pain, with almost complete inability to take food. She was wasted, anæmic, and a complete invalid, and was unable to take any exercise. The whole colon was tender to pressure. On May 13th, 1896, the first stage of right lumbar colotomy was performed, the bowel being opened six days later. The patient was relieved from pain and gained steadily in strength. In May, 1897, the artificial anus was closed. In November, 1898, she said that she was perfectly well, she ate ordinary food and took active outdoor exercise. Case 2 — The patient was a woman aged 31 years. In September, 1896, she began to have abdominal pain and soon, because of the pain, gave up taking solid food. Her illness continued until her admission into Guy's Hospital, under the care of Dr Pye-Smith, in December, 1897, when she was found to be passing membrane. She was then very anæmic and weak and was suffering severely. As she became worse in spite of all medical treatment the first stage of right lumbar colotomy was performed on March 3rd, 1898, the bowel being opened on March 8th. She remained four months in the hospital and when she left she was in perfect health and had remained so up to the last time she was seen. It was proposed to close the artificial anus this spring. The patient was averse from hurrying as she was so well in the present condition. Case 3 — The patient, a man, aged 35 years, had been in the tropics and Egypt. Eight years ago he had had diarrhoea with bleeding. This had continued on and off till his admission to Guy's Hospital. He had suffered much from abdominal pain. He had been treated in hospital medically without any success. He was admitted into Guy's Hospital in November, 1898. He had continuous diarrhoea, had lost control over the bowels, was very wasted, anæmic, and had the appearance of a man who had not much longer to live. As he was becoming worse, on Dec 31st, 1898, the first stage of a colotomy was performed and the bowel was opened five days later. He gained much flesh and colour, quite lost his abdominal pain, and left the hospital at the end of February feeling well enough to work and in May reported himself as very well. He was shown to the society and appeared to be well, but complained of being prevented from working owing to escape of liquid faeces from the wound when he stooped. Dr Hale White and Mr Golding Bird pointed out that all *a priori* argument was in favour of a right colotomy for chronic disease of the colon, for it secured absolute rest for that structure, and the cases now brought forward showed clearly that the colon was not necessary for the maintenance of perfect health. They recommended palliative or curative right-sided colotomy for severe and otherwise hopeless examples of the following diseases: (1) intractable membranous colitis, (2) all forms of chronic ulceration of the colon which had resisted medical treatment and which were obviously otherwise incurable, most cases of very chronic dysentery were probably to be cured without colotomy, and (3) cases of idiopathic dilatation of the colon. The colotomy must be right-sided and colotomy was preferable to colectomy, for when the

Dr. SIMMONS agreed that alveolar drainage should be the first step. In the long standing cases where it was not over the intrum should be opened and an independent opening made in the inner wall below the lacrimal culminated bone. It was usual in such cases to find papillary outgrowths.—Mr. W. J. WALSHAM also spoke. He mentioned a case in which the empyema was found to be due to a fang which had been retained when the tooth with two other fangs had been extracted.—Mr. J. THOMPSON said that he had seen cases heal after drainage for 13 months or two years. Patients did not find the drainage disagreeable.—Mr. E. E. in reply, said that he and Mr. J. THOMPSON performed simple drainage through the alveolus also. The cases which they had brought forward represented the minority in which this procedure did not cure the patient.

OPHTHALMOLOGICAL SOCIETY

Tumours of the Iris—Unusual Form of Opacity of the Cornea—Vascular Formation in the Vitreous in Diabetes—Sloughing of the Cornea rapidly following on Fracture of the Base of the Skull—Primary Carcinoma of the Eyeball—Carcinoma of the Eye Secondary to that of the Lung—Traumatic Ptosis—Piece of Glass Localised in the Eye by Means of the Roentgen Rays—Eyeball with Fragment of Steel Lodged in its Coats—Solid Edema of the Eyelids—Artificial Eyes—Filamentary Keratitis—Orbital Tumour

A CLINICAL meeting of this society was held on May 4th, Mr. H. R. SWANZY, President, being in the chair.

Dr. A. H. THOMPSON showed a microscopic section of a Tumour from a case which had been shown at a previous meeting of the society. The portion of iris containing the tumour was removed and the patient now had vision equalling $\frac{2}{3}$ in the eye. The tumour was probably a spindle celled sarcoma.

Mr. TREACHER COLLINS showed a case in which the tumour occupied the upper inner part of the Iris and the lens was cataractous. The patient was a woman, aged 63 years, who had had a black spot in the eye since childhood. The piece of iris was removed and the cataract was extracted at the same time. The growth consisted of large endothelial cells with sharply defined nuclei. It resembled in structure pigmented moles of the skin and was probably innocent.—Mr. JOHN GRIFITH thought that Dr. Thompson's case was a myoma from the root-shaped character of the nuclei and that Mr. Collins's case was a large round celled sarcoma.

Mr. TREACHER COLLINS showed an Unusual Form of Opacity of the Cornea. It was present in both eyes, but was more marked in the left. It had much the appearance of a broken cobweb stretched across the cornea, the lines were in the corneal substance. They were possibly the tracks of old blood vessels after interstitial keratitis but they were very wide for blood vessels and did not extend to the periphery of the cornea.—Mr. J. JULER thought that they were tracks of old blood vessels, there was a suspicion of scarring of the angles of the mouth which he thought made previous interstitial keratitis probable.—Dr. BREUER thought that they were the lines which were sometimes seen in the superficial punctate keratitis described by Fuchs.—Mr. SILCOCK suggested that they might be blocked lymphatic vessels which had resulted in bands of fibrous tissue.—Dr. HILL GRIFITH asked if the possibility of the lines being due to a vegetable fungus had been considered.

Mr. ARNOLD LAWSON showed a patient who had been known to be diabetic for three years and who exhibited a Vascular Formation in the Vitreous. His sight had failed for two years in the right eye and for six months in the left. The right lens was opaque, in the left eye there was at first a vitreous haze which obscured the details of the fundus. As this cleared there was found a connective tissue formation consisting of feathery tufts proceeding from a central stalk richly supplied with blood vessels.

Dr. LEBLANC showed a man, aged 33 years, who had been knocked down by an engine and who exhibited Sloughing of the Cornea rapidly following on Fracture of the Base of the Skull. When first seen he was semi comatose, he had right facial paralysis, the eye remaining open, severe scalp wounds, and the escape of cerebro-spinal fluid from the ear, the fifth-nerve was uninjured. Notwithstanding the care

that was taken of him his cornea sloughed and the eye had to be excised. The probable reason for the sloughing was the exposure of the cornea consequent on the facial paralysis and the condition of semi insensibility induced in the cornea by the partial coma.

Mr. SIMEON SNELL (Sheffield) showed a specimen of Primary Carcinoma of the Eyeball. The patient was a man aged 69 years. There was a history of an injury to the eye (cornea) 14 years before. When first seen almost the whole of the cornea was involved in a nodulated, hard, irregular growth. Careful examination failed to disclose any growth elsewhere in the body. The eyeball was enucleated the orbit was cleared out, and chloride of zinc paste was applied to the socket. The growth had perforated the globe posteriorly. Mr. Treacher Collins examined the eyeball and reported that the appearances of the growth were typically those of carcinoma and that it originated within the globe but in which structure it was impossible to say.—Mr. COLLINS said that it was formerly the opinion that growths primarily occurring in the eye were sarcomata or gliomata but it was known now that carcinomata occurred starting from the tubular glands of the ciliary body, they might also start in the pigment epithelium of the iris and choroid he thought that Mr. Snell's case probably originated in the ciliary body.—Mr. SILCOCK had seen orbital tumours having a structure similar to the one in question, possibly these might be endotheliomata and not epitheliomata.—Dr. BROWN remarked that as visceral carcinoma might exist for a long time without revealing itself they ought to be cautious in accepting a carcinoma in the eye as a primary growth.—Mr. JESSOP asked whether there had been any recurrence.

Mr. JOHN ROWAN showed a specimen of Carcinoma of the Eye Secondary to that of the Lung. It was a scirrhous cancer occupying the lower part of the fundus and detaching the retina, its origin was in the glands or mucous membrane of the bronchi, the primary and secondary growths were similar in character.

Mr. SNELL showed a stereoscopic photograph of a case of Traumatic Ptosis.

Mr. MACFENZIE DAVIDSON showed a Piece of Glass localised in the Eye by means of the Roentgen Rays. A fragment of a Florence flask during a chemical experiment went into the patient's eye. It was shown by the x-rays quite clearly, but was less dense than metal in appearance. The only modification of method used in this case was that the rays were passed obliquely through the eye so as to avoid bone as much as possible.

Mr. GEORGE MACKAY showed an Eyeball with Fragment of Steel Lodged in its Coats with skin rams. A traumatic cataract had been formed, which was removed, leaving the media clear. The position of the foreign body could be seen by the ophthalmoscope. As it appeared to be encapsulated it was not interfered with, after an interval of quiescence the vision failed and the eye became irritable, the iris had a tawny brown colour. Removal of the foreign body by the magnet failed. After enucleation it was found fastened to the coats of the eye. In order to trace the parts of the eye discoloured by the rust of the iron Prussian blue was formed with it, the corneal epithelium and the filtration angle were the parts most widely stained. Descemet's membrane escaped.

Mr. ANDERSON CRITCHETT showed a case of Solid Edema of the Eyelids. The patient had erysipelas in 1894 followed by another attack later. Fullness of the lids followed, they were treated by pressure, puncture and incision without benefit. The mass had been excised by Mr. Higgins but had recurred. Mr. Eyre had photographed the same case five years before. At that time the upper lids were more swollen than the lower. He had seen seven similar cases, all of them after erysipelas.—Mr. FROST, Mr. SILCOCK, and Mr. MACKAY spoke of similar cases.

Mr. CRITCHETT also showed samples of Snellen's Artificial Eyes.

Dr. RAYNER BATTEN showed a woman, aged 29 years, with Filamentary Keratitis. She had had chronic conjunctivitis one year. A number of threads were seen hanging from the surface of the cornea near its edge, they were about one millimetre long and consisted of a twisted rope of epithelium. No vesicles were seen. They were symmetrical in the two eyes.

Mr. J. JULER showed a case of Orbital Tumour. There was a history of proptosis for two months. A fluctuating tumour was felt at the upper inner margin of the right orbit, dark

one of 10 months pregnancy. Dr. Braithwaite saw the case in consultation.

The following cases, pathological specimens, &c., were shown—

Dr. ALLAN. A Ball showing Localised Hyperpyrexia from a patient who suffered from tuberculous.

Dr. BARRS. Tubercle Bacilli from a Placental Effusion.

Mr. LITTLEWOOD. Perforated Gastric Ulcer treated by excision of the ulcer and closure of the peritoneum (specimen and specimen shown).

Dr. WARDROP GRIFFITH. Cirrhosis of the Liver with Hemorrhage from the Gastrogastric Veins.

Mr. W. THOMPSON. Infamed Testicle with Twisted Cord simulating Strangulated Hernia.

Dr. CHURTON. A specimen of Dilated Prostatic Urethra Bladder Urethra, &c. from a boy eight years of age, supposed to be in good health until six days before his death (from uræmia).

Dr. MANTLE. A Recent Addition to the Royal Edinb. Infirmary Museum—Droptical Membrane.

Mr. WARD. Hydronephrosis from Impacted Calculus.

Mr. SECKER WALKER. Dr. Ascher's Transparent Parimeter for Rap & Measurement of the Field of Vision.

Dr. TREVELYAN. A Case of Lupus of the Lip in a girl, aged 19 years, who had scars of old lupus on the face.

The annual meeting of the society was held at the close of the ordinary meeting. The annual report and balance-sheet were presented and passed. The members of the society numbered 340 and the average attendance at the meetings had been 60. The following officers were elected for the ensuing year—President Professor C. J. Wright. Vice-presidents Dr. Gordon Black (Harrogate) and Dr. A. G. Barrs. Mr. Edwin Lee (Dewsbury), Dr. Muirhead (Harrogate), Dr. Wardrop Griffith, Dr. H. J. Clarke (Doncaster), Mr. B. G. A. Moynihan, and Mr. Secker Walker took the place of the six retiring members of the committee. Honorary secretaries Dr. E. F. Trevelyan and Mr. Lawford Knaggs.

EDINBURGH OBSTETRICAL SOCIETY

Edema Glottidis during Pregnancy—Puerperal Hyperpyrexia—Pelvic Contraction—Peritoneal Effusion—Exhibition of Specimens

A MEETING of this society was held on May 10th, Dr. HALLIDAY CROOM, President, being in the chair.

Dr. LUOAS read a paper on a Fatal Case of Edema Glottidis during Pregnancy. The patient who was in about the eighth month of pregnancy developed an acute inflammatory affection of the larynx with a temperature of 101° F. There was no membrane on, or congestion of, the pharynx, no membrane was coughed up nor were there any enlarged glands. The urine was free from albumin. The patient died in three days, having refused to allow tracheotomy to be performed.

Dr. J. LAMOND LACKIE read a paper on Puerperal Hyperpyrexia with an illustrative Case. Hyperpyrexia, he said, might be broadly divided into two classes—the pre-lethal type of Wunderlich and those cases in which the high temperature occurred some time before the death of the patient and was in itself the direct cause of a fatal issue or from which the patient recovered. The pre-lethal type in obstetric practice was probably met with most commonly just before death from eclampsia. But hyperpyrexia occurring during the course of a puerperium must be extremely rare. Pye-Smith of Sheffield recorded a case where after a first normal labour the temperature ranged from 104° F. to 108° F. for three weeks. Wunderlich stated that after parturition the temperature might reach 107° F. and in a few days fall to normal without any apparent cause. A case was recorded where the temperature rose to 110° F. at death on the tenth day following labour, this was probably due to hæmorrhage. The following case was of interest. A red-tube years, with five children, each being delivered with difficulty by forceps owing to a contracted pelvis, showed a labour with her sixth child. On the eighth day after labour, as a result of her previous labour, an engine was torn that the tear, to the left rapidly following a laceration of the fornix. She had been in the first stage of labour for 12 hours and was in danger of death. The patient was uninjured. N

did perfectly well until the fourth day, when she had suddenly a severe rigor with a temperature of 106° F. An ice vaginal douche was used and an ice-bag was given and an ice-bag was administered. Two hours later the temperature was 105° and the patient was delirious, and the pulse was very feeble and so rapid that it could not be counted. An ice-pack was given and the temperature was again in the rectum every 10 minutes. This gradually fell to 103° and after suspension of the ice-pack went down to 99° F. The patient seemed much better and consciousness had returned. For 20 hours she continued fairly well when another rigor occurred, the temperature rising to 110° F. The patient was quite comatose and apparently dying but the same treatment restored her to consciousness and a favourable issue. Meanwhile, intra uterine douches were used every four hours and per vaginam nothing unusual could be felt. 24 hours after this attack she had another rigor the temperature rising to 110° F. and shortly afterwards to 112° F. The patient was comatose and no pulse could be felt at the wrist. Her breathing was stertorous and death was expected every minute. The ice was again applied; 20 grains of atropine were administered per rectum and an anæsthetic douche was given when a large clough came away with a great quantity of smelly discharge. The temperature gradually fell to 104° F. when the special treatment was suspended and stimulants were given freely by the mouth and subcutaneous. The temperature gradually fell until it was very subnormal, on the next day it was normal. A large coagulable fibrin formed, so large that it admitted two fingers. The patient made an excellent recovery and the fibrin was afterwards successfully operated on. This was a case of severe sepsis, there being no evidence of pyæmia or septicæmia, the case of pyæmia poisoning was so severe as to cause hyperpyrexia on three successive nights. Pyæmia and septicæmia, without any reference to the puerperium account for 17 per cent. of the cases of temperature above 106° F. but Dr. Lackie could find no record of a case in which an absorption, as occurred in sepsis, was the cause of hyperpyrexia. Before the third rigor there was a peculiar restlessness especially in the eyes, and a deceptive sense of well-being in the patient. This condition had also been noted in acute chloæmia as preliminary to hyperpyrexia. As regards the treatment, an ice-pack was used as the cold bath treatment was at the moment impossible. The latter through the necessary movement threw a greater strain on the heart. The temperature should be reduced by active measures till it was midway between the highest recorded and that to which it was desirable to fall. Experience showed that the temperature continued to fall just as much after as during the application of ice or the use of the cold bath. The President mentioned a case which he had seen where the temperature rose to 110° F. for three successive nights. It was evidently neurotic in origin.

Dr. HAIG FERGUSON read a paper on Labour complicated by a minor degree of Pelvic Contraction in Primipara and Multipara.

Dr. FORDYCE read notes on two cases of Peritoneal Effusion.

Dr. J. W. BALLANTINE exhibited frozen sections of Iniencephalic Fœtus, Anencephalic Fœtus, and Fœtus with retroflexion of the spine, &c.

Dr. FORDYCE showed an Ovarian Tumour with a pedicle twisted to the size of thin cord, it was removed from an insane patient whose mental condition had not undergone any improvement as a result of the operation.

The President showed a Cystic Ovary removed from Mittelschmerz and an Ovarian Tumour from a patient, aged 63 years, who developed dementia and died in six weeks.

IPSWICH CLINICAL SOCIETY—A meeting of this society was held on May 11th, Mr. S. O. Eades, the President, being in the chair. Mr. Hoyland showed three young patients with Mitral Disease, to illustrate the marked contrast in general physical development met with in the subjects of heart lesions. Mr. Fryer showed a man in whom the physical signs of both Mitral and Aortic Regurgitation were present, the murmurs being audible over a very large area. There was marked pulsation of the carotids and pulsation of the retinal artery alternating with a venous pulse. The man enjoyed good health. Mr. Fryer also showed the Suprarenal Bodies from a case of Addison's Disease in which there had been very little pigmentation. The left

supra-natal body was diseased—Mr Rades showed a case of Chronic Dry Eczema—Mr J R Shaddon showed a man with a Roundabout Boy, Hard Prominence on the Right Posterior Wall of the Pharynx. He considered that the case was one of disease of the cervical vertebrae, probably the result of previous caries—Dr Brogden read notes of a case of Diptheria in which antitoxin was administered. The attack was a mild one, but 12 days after apparent recovery a rash resembling that of scarlet fever appeared, with rapid pulse and high temperature. The patient was very ill, much more so than during the diptheritic attack. Dr Brogden was inclined to ascribe the second illness to the effect of the antitoxin—Dr H H Brown showed the Appendix Vermiformis removed from a case of Reoerting Appendicitis in a boy. The operation was one of considerable difficulty owing to the firm matting together of the cecum, omentum, and intestine. The patient made an excellent recovery—Mr Corie showed (for Dr Vincent) a woman with an Abdominal Tumour the exact nature of which was doubtful. It was impossible to say from the symptoms whether it was an menial growth or a fibroid growth from the uterus. 2 Cases of (?) Chronic Meningitis were probably to specific disease of the cranial bones with adherent cicatrices in the scalp. The patient suffered from insomnia and was said to have had some maniacal attacks, was added to the use of morphia. His condition was improving under iodide of Potassium—Mr Rossack opened a discussion on the Freeseb Epidemic of Influenza. He referred specially to the period of incubation, which appeared to vary to the slow pulse and subnormal temperature met with, and to the excellent effect of anisepic treatment in restoring the pulse and the temperature to the normal. He had seen six cases of incubating influenza following influenza and jaundice was mentioned as a rare sequel—Dr H H Brown considered that the period of incubation was generally about five or six days and mentioned that the Clinical Research Association now advertised that they could confirm the diagnosis by a bacteriological examination of the sputum. He also mentioned a case in which acute diabetes of severe type followed influenza. The case recovered rapidly under treatment, although the patient appeared to be almost in extremis for some years diabetes recurred and the patient died. A similar case had been recorded and it was an interesting question why diabetes occurring as a sequel of influenza should be more amenable to treatment than when it occurred independently, as it certainly seemed to be in this case—A Rowler Ward, Mr Fildmore, Dr Ward, and Dr Sinclair took part.

GLASGOW OBSTETRICAL AND GYNECOLOGICAL SOCIETY—A meeting of this society was held on April 26th, Mr Alexander Miller being in the chair—Dr John H. Hunter read a paper entitled, "William Hunter, Anatomist. A Lecture with Demonstration of Preparations from the Obstetrical Series of the Hunterian Museum in Glasgow." The lecture commenced with a protest, implied by the title, against the commonly accepted view that it was an obstetrician that William Hunter deserved to be remembered. Though nowadays his reputation was chiefly obstetrical and rested on the name of his great work of obstetric anatomy ("Hunter's Gravid Uterus") and the share he had in reforming the practice of midwifery in England it was to anatomy and to the organization and reform of medical education that his real talents and fortune were chiefly devoted. The revolution which William Hunter effected in the teaching of anatomy by the establishment of full systematic courses of lectures, and of facilities for dissection by students, and his views as to the importance of anatomy and what a teacher of it should aim at were briefly set forth. Dr Teacher next traced the early part of Hunter's career and the circumstances which chiefly determined the direction, the friendship with Galien, which turned him from anatomy to the study of anatomy, and the means by which he made himself fit to do so. In regard to the last Dr Teacher returned particularly to his early anatomical writings which studies in Paris in the winter of 1743-44, regarding which information had been obtained from papers preserved in the Hunterian Museum, and his second visit to the continent in 1746-47. Hunter's first opportunity of teaching came in 1746

In the form of an invitation from a "Society of Naval Surgeons" to give a course of lectures on operative anatomy, out of this course arose, the famous Great Windmill Street School of surgery to midwifery were then which turned Hunter from surgery to midwifery and indicated and his practice as a physician and accoucheur (and anatomist) was illustrated by giving an account of his diary of attendance on Queen Charlotte, which was preserved in the Hunterian Museum, and by quotations from his midwifery lectures relative to parturient fever, bleeding in pregnancy, the forceps, and craniotomy. The meeting concluded with a demonstration of specimens from the obstetrical series of the Hunterian Museum illustrating the anatomy of the placenta, decidua and the independence of the foetal and maternal circulations. The demonstration closed with an exhibition of the beautiful dissection of the gravid uterus in the fifth month which was figured in the portrait by Sir Joshua Reynolds, and which was of special interest as being from the case in the investigation of which William Hunter discovered the truth in the unrecognized condition of retroversion of the gravid uterus.

FORANATHIR ALIBICAL ASSOCIATION—A meeting of this society was held on May 3rd, Dr Mackenzie Whyte, Vice President, being in the chair—Professor Kynoch showed a Uterus removed by Vaginal Hysterectomy for cancer of the cervix—Dr Buist showed drawings of a liver from a case of Acute Yellow Atrophy and of microscopic sections of it. He then quoted statistics of cases in several hospitals of acute yellow atrophy and the relative frequency of its occurrence in cases of pregnancy which he considered was not necessarily a factor in this disease. A case had been under his care which simulated acute yellow atrophy of the liver but proved to be toxemia from obstruction—Dr Mackenzie Whyte read a paper on the cases of Chronic Tuberculous Peritonitis which had been under his care in the Dundee Royal Infirmary during the last five years and a half. They were 11 in number, nine were dead, one was in a hopeless condition, and one had recovered completely. The single case in which laparotomy had been performed had died and though most of the cases seemed unsuitable for operation when admitted still it was thought it might be more frequently tried. Familly tuberculosis was present in seven. In three cases there were marked pleuritic symptoms and in three there was old tuberculosis of the lungs—Mr Greig then continued his communication on "Two Years in the Surgical Out-patient Room of the Infirmary." In it he discussed the cases of kyphosis and scoliosis. He pointed out the difficulty of treatment of these cases in the surgical out-patient department and recommended that with the dorsal position as being likely to afford more support to the spine. In the next place tuberculous disease of bones, osteomyelitis, periostitis, and osteitis were considered. Lumps were briefly mentioned, especially as regards the parts affected, the age, and sex. Tuberculous adenitis was then referred to and the treatment briefly discussed. Then spoken of, after which short details were given of the cases of rheumatic arthritis, osteo-arthritis, and several varieties of congenital deformities—e.g., retained testis, cleft palate, and nerves.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOROLOGICAL ASSOCIATION—A general meeting of this society was held on April 26th, Mr Lennox Browne reported nature of the case of Laryngeal Epithelioma of at least two and a half years' duration exhibited by him at the last meeting, he had removed a portion of the growth and submitted it to Mr Wyatt Wrigglesworth who reported that it was a diffuse papilloma undergoing slow malignant transformation. Mr Wyatt Wrigglesworth said there was a tendency for the cells to group themselves into nests. He concluded that what was in the first instance a comparatively quiet papilloma was probably undergoing active change strongly suggestive of histological malignancy—The President described a case of Hystrical Abdomin which had lasted 11 years. After a severe mental shock the patient had become mute and had remained so for three or four years, when she

began to whisper, and in the past two years had developed a deep rough voice, which the laryngoscope showed to be produced by vibration of the false vocal cords (taschenbandsprache). All methods of treatment were tried in vain, but the voice returned suddenly six months ago after exposure to great excitement and had remained normal ever since.—Dr Abercrombie showed a case of Laryngeal Papilloma with Apparent Defect of the Posterior End of the Left Vocal Cord in a boy, aged nine years, the subject of nasal obstruction from hypertrophied tonsils and adenoid growths.—Dr Dundas Grant showed a case of Asymmetry of the Frontal Sinus revealed by operation.—Mr Obichela Nourse showed a case of Empyema of the Frontal Sinus treated through the Infundibulum.—Dr Dundas Grant showed (1) two cases of Radical Operation for Chronic Suppurative Otitis, and (2) a case of Atresia of the Right External Auditory Meatus.

Reviews and Notices of Books.

A Manual of Surgical Treatment. By W. WATSON CHEYNE, M.B. Edin., F.R.S. Eng., F.R.S., Professor of Surgery in King's College, London, Surgeon to King's College Hospital, &c., and F. K. BURGARD, M.D. M.S. Lond., F.R.S. Eng., Teacher of Practical Surgery in King's College, London, Surgeon to King's College Hospital, &c. In Six Parts. Part I. London and Bombay Longmans, Green, and Co. 1899. Pp. 285. 8vo. Price 10s. 6d.

THE chief end of surgery is treatment. However interesting pathology may be its importance is almost entirely dependent on the fact that it points out the directions which treatment must follow. Of late years, however, there has been a tendency to magnify the office of pathology at the expense of treatment and indications; thus are to be observed in some text-books, where space devoted to the pathology and therapeutics of a disease does not correspond with their relative importance. The vast increase, moreover, in all branches of surgery in recent years has made it necessary that in a text-book of the science the descriptions of treatment must be abbreviated if it be desired to keep the work within a reasonable size. A real want, therefore, exists for a work in which the accounts of the treatment to be followed are sufficiently detailed, to enable readers to conduct the treatment of a case, but in order to prevent the book assuming too great a size something must be omitted, and as numerous treatises exist which deal fully with the pathology of disease and say but little of the treatment, so the pathology may safely be omitted from a work which has to do primarily with treatment. These observations indicate fairly exactly the scope of the work of which the first part lies before us. It is intended to give full details of the treatment of surgical cases from the commencement to the termination of the illness, and the pathology and symptoms are only referred to in so far as is necessary for the appreciation of the principles of the treatment. The authors have not attempted to describe all the methods of treatment which have been or even now are practised; but they have in the main described chiefly those methods which appear to them to be the best, but they refer also, though in less detail, to other methods which are recognised as valuable at the present day. It is obviously difficult to express an opinion of a work of which we have had an opportunity of examining only one sixth part, but if the succeeding volumes equal the first there will be no two opinions as to the great practical value of this treatise.

This first part contains the treatment of general surgical diseases, including Inflammation, Suppuration, Ulceration, Gangrene, Wounds and their Complications, Infective Diseases and Tumours, and the Administration of Anæsthetics. We will take this last section first. The chapter on

anæsthetics has been contributed by Dr J. F. W. Silk and it is most ably written, it is evidently based on a very wide personal experience of the administration of anæsthetics and it should prove of value, not only to those who act as anæsthetists, but also to all who have anything to do with operations and notably to the surgeon. Especially useful are Dr Silk's remarks on the factors which determine the choice of an anæsthetic and he wisely points out that an anæsthetic may be perfectly safe in the hands of an administrator accustomed to its use and yet be highly dangerous when given by one who has had little previous experience of it. The account of the treatment of the difficulties and dangers met with in anæsthesia is good and so also is the description of the various methods of producing locally absence of sensibility. To only one statement in this chapter do we venture to take exception, on page 83 we are told that 150° F. is "as hot as the hand can bear", a very simple experiment with a bath thermometer will show that 150° is a much higher temperature than most hands, at least, can bear.

Inflammation and its Treatment are dealt with in 'Chapter I', and especially good is the account of the methods of general and local blood letting, therapeutic measure which are too much neglected at the present day, but it was surely hardly necessary to figure the spring scarificator, for it is practically never employed at the present time. The subjects of Acute Suppuration and Ulceration occupy the next two chapters and in this connexion Thiersch's method of skin grafting is fully and carefully described. The very good results which may be obtained by the employment of this method depend chiefly on small and apparently unimportant details and all these minutæ of treatment are here to be found. The authors classify gangrene as direct, indirect, and specific. It would probably be better to call the first variety "direct traumatic," for some of the specific forms are equally "direct." In the prevention of bedsores there is nothing better than a properly filled water bed, but much of its value depends on the bed being filled to the correct degree, and this point has not been forgotten, for the authors describe carefully the degree of fullness required.

An important chapter is that dealing with the Treatment of Wounds. In this, after an account has been given of the value of cold as a hæmostatic, we are told that "almost equally efficacious in arresting bleeding is heat." We should certainly feel inclined to place heat far in advance of cold as a hæmostatic, for the influence of cold in most cases passes off rapidly after a dressing has been applied, while the effect of heat, from 110° F. to 115°, is much more permanent. A useful account of saline transfusion for hæmorrhage is given and we coincide with the authors in the opinion that a description of the methods of transfusion of blood, either pure or defibrinated, would take up space which might be more usefully employed otherwise. We think, however, that the authors are under a misapprehension in saying that, in the transfusion of blood "the red blood corpuscles introduced soon die", this only occurs when the blood of one animal is introduced into an animal of a different species and is probably dependent on the difference in the composition of the liquor sanguinis in the two cases.

It might have been pointed out that the entry of air into veins appears to be less common nowadays than formerly and this is in all probability due to the use of anæsthetics by which the vigour of the respiratory movements is restrained and the systemic veins are usually overfilled, so that if a vein in the "dangerous area" be wounded blood is more likely to flow from the vessel than air to enter it. The chapter on the treatment of wounds is very good and we need only mention specially the description of the button hole suture, it often happens that those who are not in the habit of employing this stitch experience some difficulty in finishing it off. Three methods in which this may be done

are figured here, the nearest is that in which at the last stroke the needle is introduced in a direction opposite to the other stitches.

The septic complications of wounds are well described and an interesting theory to explain the action of nitrate of silver in limiting the spread of erysipelas is given, it is suggested that the cause excites a leucocytosis in the part which by the phagocytic action of its component corpuscles acts as a barrier to the onward progress of the micrococci. A brief but very lucid account is given of the treatment of syphilis and a description of the soft sore follows. It is stated that the chancreoid "generally occurs on the prepuce or glans penis," from which it might be gathered that it is rare on the vulva, the statement is of course true if the words "in the male" be inserted.

Chapters on the General Treatment of Tuberculous and of Tumours, Innocent and Malignant, follow. These refer only to the general principles of treatment and more detailed accounts will be given with the surgery of the special organs and tissues. We have derived much pleasure from the perusal of this part and shall look forward with interest to the appearance of the succeeding sections of the work. The most marked characteristic of the book is the essentially practical nature of the descriptions. The authors are to be congratulated on the successful commencement of the first portion of an arduous task.

Traumatic Separation of the Epiphysis. By JOHN POLKAD, F.R.C.S. Eng. With 337 Illustrations and Stenograms. London: Smith Elder, and Co. 1898. Royal 8vo. Pp. 926. Price £2 12s. 6d.

THE old Greek saying that a large evil is not universally applicable, for the book before us is certainly great, as it extends to nearly 1000 pages, yet it is very far from being an evil for it is a very valuable contribution to an important department of surgery. There is, perhaps, no more treacherous error of diagnosis than one mistaking the separation of an epiphysis for a fracture, and, indeed, this mistake is very pardonable, for the amount of information on the subject which is to be found in most of the text-books of surgery is very small. Yet the condition is by no means rare, for Mr. Poland has collected notes of more than 700 cases.

The first chapter deals with the history of the subject, and from it we learn that a sentence in Hippocrates may refer to this lesion, for in speaking of dislocation of the wrist he says that the epiphysis is sometimes displaced but that was his exact meaning cannot now be determined. A much more definite reference occurs in a book by Realdus Columbus in 1559 and from that time to the present the references in surgical literature increase in frequency and the citations from writers of the present century alone fill several pages, but curiously in 1850 Dr. A. Coulon of Paris in a treatise on fractures in children, denied the existence of these injuries and many other writers, while not venturing to deny the occurrence of the lesion, have considered them to be so rare that they are of little practical importance. During the last 20 years it has gradually been acknowledged that the injury is by no means rare and Curtile in 1891 considered that 20 per cent of all fractures in children were really cases of separation or an epiphysis.

The next chapter, on the Anatomy of the Epiphysis is extremely good and it is illustrated by a series of 19 stains taken by Mr. William Webster, they show the appearance of the hand and wrist at various ages from the end of the first year to the seven-eighth year.

With regard to the etiology the author considers that the causes producing these traumatic separations are practically the same as those of fracture but as a rule they are more severe, although in some cases as in hyper-extension of the

JOURNALS

Medical Chronicle—The March number completed vol. x. of its series and the April number marks the commencement of vol. i. of the third series. Simultaneously the duties of editor are taken over by Dr. R. P. Williamson, assistant to the professor of medicine, Owens College, with Dr. F. J. H. Coultas as sub-editor. The journal is produced under the direction of a number of guarantors of whom Professor D. J. Leach is chairman and Professor Sinclair Sheratt and Hughes, 27, St. Ann street, Manchester and the familiar redish brown cover has given place to a light blue one. The annual subscription remains 12s. 6d. as before. The original articles in the April number are (1) by Mr. E. Stannmore Bishop on the Sealing of Operative Wounds about the Abdomen *review Treatment by Dressing*, (2) by Dr. J. S. Symmetrical Gangrene, and (3) by Professor Delpech on the Effects of the Pollution of Water supplies.

Edinburgh Medical Journal—In the May number Dr. William Osler of Baltimore describes three cases of Gastro-intestinal Hemorrhage occurring in patients who suffered from primary chronic enlargement of the spleen with ascites the condition called splenic aneurysm by Griesinger. The bleedings were very profuse and occurred from time to time during a period of from nine to 12 years while in the intervals the patients regained their flesh and strength and were able to carry on their occupations. Dr. Osler agrees with Sir Thomas Watson in considering the etiology of the hæmorrhage to be mechanical congestion. Dr. A. J. Gillespie relates his experience of a visit to the Falkenstein

On the whole the prognosis is good in these injuries, one of the most troublesome results is arrest of growth of the affected bone and this is especially harmful in the forearm or the leg, where the unequal growth of the two bones leads to distortion. Ankylosis also is not rare as these injuries in the limbs are close to joints.

With each quotation the author gives the reference to the book from which he has taken it, a practice which should be more widely followed. An elaborate index of names referred to is given and there is an equally complete index or subjects. The printing and paper of the book could not be better. In conclusion, we may say that the work may be considered a complete exposition of the subject of which it treats and that for many years to come it will be, not only in this country but abroad also the standard work on traumatic separation of the epiphyses.

Sanatorium for Phthisical Patients—There are four other original articles

Dublin Journal of Medical Science—In the opening article of the May number Dr H G Drury draws a dismal picture of the Prevalence and Effects of Morphinomania or the Uncontrollable Craving for Morphia Administered by Subcutaneous Injection Dr Drury discusses the treatment of morphinomania at some length, giving the preference to gradual reduction of the drug, and mentioning the use of atropine and permanganate of potassium as partial antidotes

Analytical Records

FROM

THE LANCET LABORATORY.

TABLOIDS CONTAINING ARTIFICIAL EFFERVESCENT MINERAL WATER SALTS

(BURROUGHS, WELLCOME, AND CO. SNOW HILL-BUILDINGS E.C.)

We have examined two types of this useful application of the tabloid—namely, the tabloid representing artificial Carlsbad salt and the tabloid representing artificial Vichy salt. In addition to the salts which are identical with those of the respective springs indicated the tabloids contain ingredients which on interaction in water give rise to an agreeable effervescence. The Carlsbad tabloid contained the chief active constituent of this celebrated spring while the Vichy tabloid contained besides alkaline salts some magnesium salts. In the same way tabloids are prepared representing Kissingen, Seltzer, and Vichy with lithium

VERNISOL

(JOHN BELL AND CO. 225, OXFORD-STREET W.)

Vernisol is described as a skin varnish with the advantage of being soluble in water. On rubbing the preparation uniformly on the skin a clean protective film remains after a short time. According to our examination the yield of film is about one sixth of the total substance. Vernisol is yellowish brown in colour and has a jelly like consistence. It possesses the desiderata of a skin varnish—viz, is tenacious, pleasant to use, free from irritants, and may be easily removed by ordinary washing. Vernisol is contained in collapsible tubes and is combined with all the well known antiseptics

ANTI RHEUMATIC BREAD

(JOHN LAW AND CO. 219 STIRLING ROAD GLASGOW)

The makers of this bread evidently feel justified in calling it "anti rheumatic" on account of the fact that it contains alkaline potash salts and salicylate of soda. We do not approve of the administration of drugs in food in this manner. In the present instance it is quite possible that the salicylate in arresting the digestive processes would set up dyspepsia. We must allow that the bread is ingeniously prepared, its taste is good and nutty, its texture satisfactory, and the fact that drugs are present would barely be suspected. We note that the bread "may be had from any first-class grocer in the city. Assuming that this should prove a satisfactory way of administering salicylate of soda, under no circumstances should it be tried apart from medical advice. The bread gives a strong violet colour with a few drops of perchloride of iron, while a drop of "alkaline indicator" gives a marked positive reaction

PHENALGIN

(THE ETHA CHEMICAL CO. 313, WEST STREET NEW YORK LONDON AGENCY: L. J. REID, 11, DUNEDIN HOUSE, BASINGHALL-STREET E.C.)

Phenalgine is, according to our analysis, a combination of a well known coal tar derivative—an antipyretic and analgesic—with carbonate of soda and ammonia. This

class of compound is often intended for popular use in headache and other common maladies. The coal tar antipyretics, such as antipyrin, antifebrin, and phenacetin, are dangerous in lay hands. The physician knows when these substances are likely to be of service and is perfectly well aware how to combine them for administration. We strongly deprecate the indiscriminate sale of these coal tar derivatives combined with alkalies under proprietary names as certain remedies for various common complaints

ESVACH WATER.

(DAVEY HILL AND SON, YATES AND HICKS, 64, PARK STREET, SOUTHWARK S.E.)

This is not a natural mineral water, though its name might lead to that impression. Most natural mineral waters of the purgative saline class contain that almost inevitable constituent of natural waters, lime, but Esvach water would appear on our analysis to be free from lime salts. What it does contain according to our analysis will be seen from the following figures: magnesium sulphate, 24.65 grammes per litre, sodium sulphate, 11.36 grammes, and carbonate of soda, 6.57 grammes. The total mineral contents thus amount to 42.58 grammes per litre. The specific gravity was ascertained to be 1.0425. The therapeutics of Esvach water will be understood from the results of this analysis

DAHL'S STERILISED DOUBLE CREAM.

(DAHL MILK CO. DRAMMEN, NORWAY AND HERBERT FRANCIS AND CO., 3, ARTHUR STREET WEST R.O.)

The method employed for the sterilisation of this cream must be regarded as quite satisfactory since on opening the tin not only was the contained cream in perfectly sound condition, but it possessed a flavour closely approaching that of the fresh article. It was practically free from that "scalded" flavour which characterises most tinned dairy products. On analysis the following results were obtained: water, 62.64 per cent, fat, 30.00 per cent, mineral matter, 0.45 per cent, milk sugar and proteids, 6.91 per cent. The cream is of excellent quality and free from preservatives. In some instances cream might suitably and with advantage replace cod liver oil as a special food and therapeutic agent

ÉVIAN GROTTES MINERAL WATER.

(RICHARD DAVIS 20 MADDOX STREET REGENT-STREET W.)

This water is derived from Évian les Bains, where occurs a very interesting and remarkable group of caves or grottoes. It is well suited for table use and adapted in some cases for definite treatment since it is mildly alkaline but free from an excessive and what often proves to be objectionable amount of salts. The only mineral ingredient of importance according to our analysis is carbonate of soda, of which we found 0.37 gramme per litre. There is but a trace of common salt present. The total residue obtained on evaporation amounted to 0.45 gramme per litre. The water is free from saline taste but not insipid. We obtained no evidence of organic impurity

(1) ACOINE AND (2) HYRGOLUM

(BURGOYNE, BURBIDGES AND CO. 12 AND 16, COLEMAN STREET E.C.)

Acoine is described as a new local anæsthetic and rejoices in the name "diparamyl monoparaphenetyl guanidine hydrochlorate." We prefer the abbreviated name, having once satisfied ourselves that the acoines are alkyl-oxyphenylic guanidines and that they would appear to offer some advantages over cocaine in producing anæsthesia. It is said, for example, that the acoines do not give rise to the symptoms of poisoning sometimes caused by cocaine. An important paper detailing many experiments on the anæsthetic properties of acoine appears in Part I of the *Therapeutische Monatshefte*, 1899. The results are interesting, tending to show that in acoine we possess a new substance for producing satisfactory local anæsthesia. Hyrgolum is described as a new allotropic form of metallic mercury

From a few experiments which we have made with it we cannot allow that it is strictly speaking an allotropic form of mercury. Thus on heating it splits up into mercury and ammonia gas. It is a hard, brittle solid, somewhat resembling the black scales so often seen in the forge of a smithy.

(1) ANTIVIRGIN (2) FLUOR RHUMIN AND (3) EPIDERMALIN

(T) CHARTER AND CO 25, LIME STREET E.C.

These three compounds are derived di fluor-di phenyls

The formula for di fluor-di phenyl is $C_6H_5.F_2$ and is

obtained by acting upon certain phenyl compounds with con-

centrated hydrofluoric acid. Antivirgin is an ointment con-

taining di fluor-di phenyl and is described as "a certain cure

for whooping cough and diseases of the throat and neck,"

is another ointment containing as a basis fluor phenetol di

fluor-di phenyl and is said to give marked relief in

rheumatism, lumbago and influenza. Epidermalin is a related

compound but with xylol in the molecule. Contained in an

ointment it is said to serve as a useful antiseptic in the

treatment of unhealthy suppurations as well as of burns.

Fluorine compounds have been known for some time as

powerful antiseptics and their combination with phenyl

groups would appear to afford a series of medicated unguents

which deserve attention.

Other Inventions.

ASEPTIC INSTRUMENTS

At the present day most surgeons will agree that any instrument which is to be employed in a surgical operation should be capable of being boiled and this is as necessary for pocket instruments as for those used in the more important operations. The figures illustrate a very neat arrangement for a portable knife which is constructed entirely of metal and may therefore be boiled. The handle encloses the blade (Fig 1) and when the handle is opened the blade is placed in position and then the handle fixes it firmly by an ingenious spring so that there is no fear of its closing unexpectedly. The blade is interchangeable with three others which are kept in a metal case (Fig 2) and these blades include all the

FIG 1

FIG 2

forms which are likely to be required. The knives are made by J. Albert Schmidt, Solingen, whose agent in London is Mr W. S. Orwell, 12, Lime street, London, E.C.

A MIDWIFERY SURGICAL CLAMP

In the old method of dividing the umbilical cord the accoucheur after tying the first thread pressed the blood in the vessels some distance along the cord which was then held by an assistant until the second thread was tied, the

ment cuts the cord and compresses both the cut ends, there- by supplying the place of scissors and ligatures. The clamp having been opened, the cord when it has ceased to pulsate is placed between the blades resting on the plain side, the knifed edge is then pressed firmly down and retained in position by the catch. The clamp is removed a few seconds after application and if the accoucheur is afraid of hæmorrhage (although French authorities say there is no need for ligatures) he can tie the cord on either side of the clamp. The instrument is neat and easy to use. Messrs Arnold and Sons, London, are the makers.

Lurgan Ireland

EDWARD MAGENNIS, M.D. R.U.I.

PLYMOUTH ASYLUM—At a meeting of the Plymouth Town Council held on May 8th the report for 1898 of the Visiting Committee of the Plymouth Borough Asylum at Blackdown was presented. This stated that the result of the recent controversy between the guardians and the council with regard to the weekly rate charged for pauper patients from Plymouth was that the council in future would pay £1000 a year extra and the guardians in future would less than formerly. The weekly maintenance rate of patients had been reduced from 12s. 1d. to 11s. 2d.

DIPHTHERIA IN LONDON—Unlike as regards amount, mortality, and relative fatality diphtheria in London in the four weeks ended on April 22nd showed great decline as compared with the like period ended on March 25th. In the earlier period the total of notified cases of the disease was 791, or 198 per week, whilst in the April period the total was only 645 and the weekly average 161. In both all sanitary districts save two were invaded, but whereas in March there were four districts with upward of 50 notified cases each and 240 in all there was only one such district in April, while the other five areas had only a total of eight cases in all. The weekly average of 46 deaths from diphtheria in the March period amounting to 166 gave place to an average of 28 in April and a total of 114 deaths. The records of the several weeks in this later period showed 31 deaths (or six below the corrected decennial average), 34 (equal to the average), 20 (being 16 below the average) and 29 (or six below the average). Had the corrected averages for the corresponding four weeks of 1889-98 been maintained the actual 114 deaths would have been 142. The case mortality yielded was 17.7 per cent in place of the 20 per cent of the March period. In the outer circle also there was a falling off in the number of deaths from diphtheria the 58 of the earlier period of which 23 were in West Ham registration district, being replaced by 44, of which 19 were in that particular area.

THE LANCET.

LONDON SATURDAY, MAY 20, 1899

THE success of the Hospital Saturday Fund in Birmingham is a matter on which its promoters may be heartily congratulated. Last year they raised the handsome sum of £17,662. In addition to £10,000 as a donation to the medical charities they devoted £5000 to the support of convalescent homes, £100 to the District Nursing Society, and £250 to the provision of surgical appliances. These are very substantial contributions which are creditable to the working classes of Birmingham, but the sum is not one whit greater than should be raised for the purpose by the working men of one of the most prosperous and thriving provincial towns in England with a population of nearly half million. The benefits of the medical charities are monopolised almost entirely by the working classes and it is not fit that they should realise their obligations and give generously to institutions which provide sick beds and the best skill and nursing for the unfortunate among their number or their families when overtaken by exceptional disease or accident. The sum contributed to the hospitals of Birmingham by the Hospital Saturday Fund is probably not a fourth of that which is required to carry them on as charitable institutions, but the whole sum raised is not far short of that contributed to the Hospital Saturday Fund of London with its enormous population, showing how much more complete is the organisation in Birmingham than it is in the metropolis.

But while we have always been ready to recognise the merits of the working classes of Birmingham and of those who lead them we have occasionally found it necessary to remind them that they were dealing with charities under public management, founded and supported by the benevolent of many generations and created for limited and specific purposes. We have noticed with regret a disposition to try experiments with these institutions and to turn them to purposes for which they were never intended. Not long ago there was an attempt to ignore their essentially charitable character and to insist that the working classes by their contributions acquired a sort of right to their benefits in respect of the ordinary ailments and diseases of life—in other words, to insist that by their contributions they were paying for that ordinary medical attendance which has always been a matter for every family to arrange and pay for privately, either by engaging the services of a general practitioner practising privately or as members of a friendly society, club, or the like. The fallacy that charitable medical institutions are to be used for ordinary disease is one which the working man would quickly perceive if the same notion were held by the rich man who contributes to hospitals. What would the working man think of a well-to-do person contributing five guineas a year and thereby claiming to have himself, his family, and his servants attended by the hospital staff and when necessary received into the beds of the hospital?

But the latest heresy of the working classes of Birmingham has reference to medical practice outside hospitals altogether. It is a proposal to establish an institute where a consultant's opinion is to be obtained for the modest fee of 10s. 6d. The scheme contemplates the hiring of consulting rooms and the engagement of consultants. It is proposed to begin tentatively with two—a "physician" and a "surgeon," each to have a salary of £500 a year. The experiment is expected "to yield a considerable profit," for in all these schemes for exploiting the medical profession, and especially the younger and more needy members of it, there is a business element to be detected. But provision is made for the experiment proving to be a financial failure. In that case two-thirds of the loss have to be met by the Hospital Saturday Fund and one-third by Mr ARTHUR CHAMBERLAIN, who has the credit—rather would we say the responsibility—of this most questionable innovation. The chance of loss, however, is regarded by Mr CHAMBERLAIN and his colleagues as very remote, "considering the present condition of the medical profession and the hospitals in the city." Exactly so. All sorts of experiments are tried with "the hospitals in the city," enormous numbers are treated with very inadequate inquiry into their fitness for such relief and the medical profession is driven to all sorts of devices to compete with the abused charities. Now advantage is to be taken of this state of matters to degrade the system of consultation. We regret that the working classes of Birmingham should be thus misled by a gentleman who must know that "consultants" are not ready-made and that the scheme is calculated to tempt two—no doubt promising—young members of the profession to place themselves in a very ungracious and undignified position. They will enter into competition not so much with consultants as with general practitioners of all ranks. They will be put forward—practically they will be advertised very loudly—as superior persons who have been persuaded to take an inferior fee, and the profits which they are expected to make will be used, not for their benefit or for the benefit of the profession, but for the glorification of the Birmingham Hospital Saturday Fund and to enable its members to try other experiments with the profession and its charities.

Dr SAUNDY, both at the meeting of constituents of the Hospital Saturday Fund and in an able letter to the *Birmingham Daily Post*, has entered a very proper protest against this scheme. Surely the least its promoters should have done before committing themselves to it by a large majority was to have taken the medical profession into consideration. Consultation is a very worthless thing unless it represents experience and reputation and the confidence of the ordinary medical attendant. We see no case at all for creating such a nondescript innovation as this consulting institute to be officered presumably by two young men at a fixed salary. Mr ARTHUR CHAMBERLAIN, although doubtless he has no such intention, is doing his best to lower the status of the whole medical profession by such schemes and he may be assured of this, that in so treating the profession he is doing an injury to the tone and standard of medical practice which will in turn injure the working classes more than his pet scheme will benefit them. When real emergencies arise the deserving poor can

always obtain at hospitals the services of consultants, and it is obvious that anything which ~~changes~~ the medical profession as a whole is not in the long run likely to work well for any class of the community. We trust that this fantastic scheme will be abandoned, at any rate, the medical profession should meet in force and utter a dignified protest against such interference with its duties.

The Leicester guardians have determined to refrain from appointing a vaccination officer to carry out the new act and they have made their refusal the occasion of preparing and circulating a lengthy memorial on vaccination in Leicester addressed to the Local Government Board. The document is a careful and elaborate attempt to obscure the question at issue by ignoring important facts and assuming the identity of things which are essentially different. In the end, indeed, it would almost seem as if the guardians had succeeded in thoroughly misguiding their own minds by their own sophistical arguments. They conclude their memorial by expressing regret that the Vaccination Commissioners' unanimous recommendation to abolish compulsion was not adopted and embodied in the Act of 1898. "Needless to say every one excepting the Leicester guardians knows that rightly or wrongly compulsory vaccination has been abolished by the Local Government Board and Leicester's power of self-decision as regards all that relates to this subject could receive no better illustration than is to be found in the fact that their elected representatives are now in the ridiculous position of publicly bawling that this abolition has not taken place. They quote from Mr. BATHURST the view that where a parent has clearly proved that he has an honest, and, strong objection in the interests of his own child to vaccinating it is useless to attempt to coerce him, but from the Act of 1898 were not to be distinguished in the important matter of the conscience clause, from prosecutions under the previous Vaccination Act. The objection of the guardians reaches its acme in their quotation from Lord SALISBURY's speech in the Upper House when, in advocacy of the conscience clause, he said to the Lords, "You will be able to induce local authorities to work with you instead of against you." That of all the local authorities in this country the Leicester body should be the one to quote these words in this connexion indicates nothing short of a sublimity either of impudence or stupidity. The Vaccination Commission did have its recommendation given effect to, Lord SALISBURY did persuade the Lords to yield, the conscience clause was granted, and now it is the Leicester local authority which refuses "to work with instead of against" the Government, and which will not fulfil its statutory duty of appointing a vaccination officer even though compulsory vaccination is abolished by means of the conscience clause.

It is hardly necessary to point out that prosecutions under the Act of 1898 will be instituted only against persons who have refused to accept the relief offered by Section 2 and that in effect the protection will be not for neglect of vaccination but for neglect of vaccination.

And Leicester having thus thrown down the gauntlet to Government and Parliament now begs of them not to take it up. "Why," say the memorialists, "why disturb the existing peaceful state of things?" for "numerous prosecutions would undoubtedly excite widespread sympathy and indignation, thus bringing the administration of the law into contempt,"—as if the extensive liability to prosecution had not been purposely created, and as if the yielding of the Government would not at once be triumphantly hailed by the guardians as evidence of the success of their efforts to bring the administration of the law into the contempt which they pretend to deprecate.

There can be no sympathy with the Leicester guardians and their extraordinary manifestoes and there can be no doubt that the Government will persevere in its determination to have a vaccination officer appointed. Not nearly all of the 70,000 uncertified children belong to parents possessed of any deep-rooted objection to vaccination and when mere indifference ceases to have its full effect—as it will cease after the appointment of an officer—there may be considerable reduction in the numbers independently of any prosecutions. It is not inconceivable, indeed that the fear of this result has something to do with the anxiety of the guardians not to appoint an officer. But in Leicester more perhaps than anywhere else in the kingdom and vaccination has become a kind of fashion, and many of the inhabitants seem to be imbued with a foolish pride in the mythical Leicester method of controlling small pox. This being so the Government will very likely find themselves confronted in the end with a serious difficulty. It notwithstanding the work of the vaccination officer many thousands of children the accumulation of past arrears, remain unvaccinated—the time allowed for their certification under the conscience clause having expired before the end of 1898—"All the Local Government Board undertake the task of wholesale prosecution which will be necessary if the new Act is to be maintained in full operation." If it is impossible to sympathise with the Leicester guardians in their alleged difficulty it will not be easy to have much sympathy with the Government in theirs, for in both cases the troubles will be great measures have been created by those who suffer from them. Had last year's Act been reasonably inclusive and complete had it contained in particular a provision for systematic vaccination or revaccination of school-children, then it might have been possible to deal with the arrears in great instalments as the age for revaccination came round. Obviously under the present Act these arrears constitute a much greater difficulty than does the routine duty of attending to infants unvaccinated and unregistered at four months of age. Even yet the Government could find an elegant, but salutary by passing a Reconciliation Bill, but if it is

[MAY 20, 1899]

persists in ignoring alike its own public promises and the best course open to it to get over a serious difficulty in the administration of the half-measure of last year, then, we repeat, it will deserve little more sympathy than do the Leicester guardians

IN THE LANCET of April 22nd we gave an epitome of what is known concerning the incidence of fatal tuberculosis on the population of this country, distinguishing its various forms and showing the mortality for which it has been responsible during successive periods of the last half-century. Next in importance to tuberculosis in the list of constitutional diseases stands cancer which, on account of its rapidly increasing fatality in recent years, has awakened an amount of general interest scarcely less than that which rightly attaches to the still excessive prevalence of tuberculous disease. The national records tell us that for some years past cancer has contributed more largely to the death roll than any other single disease with the exception of bronchitis, pulmonary consumption, and pneumonia. We have therefore determined to deal in the present article with the incidence of malignant disease on the population of England and Wales, treating the subject as nearly as possible on similar lines to those followed in the case of tuberculosis, our object being to furnish the readers of THE LANCET with a complete summary of the history of this malady, derived, as in the former case, from the National Registry at Somerset House.

In the subjoined table will be found the mean annual rate of cancer mortality at certain ages in both sexes for each of the four decennia from 1851 to 1890 and also the mean rate for the seven years ending with 1897, which is the latest year for which abstracts are available.

Cancer (Malignant Disease) in England and Wales. Mortality at Specified Ages in several Periods from 1851 to 1897

Ages	Deaths in 1,000,000 living				
	1851-60	1861-70	1871-80	1881-90	1891-97

Above 75	2341	2786	3513	4578	6135

The earliest accessible records of mortality are those relating to the 10 years 1851-60. In that decade cancer was fatal, on the average, to 317 persons annually out of each 1,000,000 of the population. The table shows that during this period cancer claimed more than twice as many victims among females as it did among males, and ever since that period the disease has shown a similar tendency although the contrast has been less strongly marked. It will therefore be expedient to consider separately the mortality of the two sexes. Taking the five groups of years consecutively we note that cancer mortality among males was equal to 195 per 1,000,000 living in the first period, 242 in the second, 312 in the third, 430 in the fourth, and 571 in the last period. Among females the rates per 1,000,000 were 434, 519, 617, 739, and 882 respectively, thus the mortality in both sexes showed a marked and progressive increase from period to period. If, therefore, the correctness of the rates be assumed without question, it would appear that within rather less than half a century the fatality of malignant disease in both sexes has at least doubled. There are good grounds, however, for the belief that the increase shown by the tables is not wholly real. Dr OGLE, for example, writing in 1885 on this subject puts the case thus: "There can be very little doubt that a considerable part in this apparent increase is simply due to improved diagnosis and more careful statement of cause on the part of medical men. Year by year the number of deaths ascribed to tumour, abdominal disease, or other similarly imperfectly stated causes has been undergoing diminution, and there has been of course a corresponding addition to the mortality under the more definite headings. Moreover, the increase of mortality from cancer has been much greater among males than among females, the rate for males having risen 62 per cent in 20 years, while the rate for females has only risen 43 per cent. Now, were the rise not merely apparent but real there would seem no reason why the male sex should have suffered more than the female, whereas the difference is readily intelligible on the hypothesis that the rise has been in great measure only apparent and due to better diagnosis. For the cancerous affections of males are in much larger proportion internal or inaccessible than are those of females and consequently are more difficult of recognition, so that any improvement in medical diagnosis would add more to the male than to the female reckoning." Again, Dr TATHAM, writing 10 years later—namely, in 1895—not only confirms the opinion of his predecessor but adduces fresh evidence to show that the increase referred to has been even more rapid since 1885 than in previous years. He has, however, drawn attention to the fact that although in recent years the recorded rates have been corrected in an opposite direction, as we shall presently show, nevertheless the increase still continues unchecked. Most of our readers will remember that ever since the year 1887 a system of inquiry has been in vogue at Somerset House, of which the object is to secure greater accuracy in the classification of such deaths as are inaccurately described in the medical certificates. The answers to these inquiries have been so useful as to lead to the transference of many hundreds of ill defined deaths to one or other of the sections under the heading 'Malignant Disease' and to increase proportionately the recorded mortality from this malady. Compensation for this change is, of course, required and this has been duly

ried out, nevertheless, after making every possible
 advance it would appear to be unsafe to compute the
 cancer mortality in the seven years 1891-97 at less
 than 551 per 1,000,000 for males and 663 per 1,000,000
 for females. These rates correspond to an average
 annual increase of 2.9 per cent, and 1.8 per cent
 respectively as compared with the mortality in 1861-70
 at table shows that during the first 25 years of life
 is mortality from malignant disease is insignificant,
 is in the period of maturity, and especially in that of
 decline, that cancer claims the greater number of its victims
 the table further shows that the rate of increase in recent
 years compared with earlier years has been by no means
 uniform at the several stages of life. Among men aged from
 15 to 45 years, for example, the rate of increase has been
 equal to 89 per cent, whilst among females at the same
 age the increase has not exceeded 37 per cent. At the
 next succeeding age group—namely, that from 45 to 55
 years—the rate of increase has been 139 and 52 per cent
 respectively, and at the age from 65 to 75 years it has
 been 167 and 99 per cent. At ages above 75 years, however,
 the difference in the rate of increase has not exceeded
 21 per cent.

In the last report of the Registrar General we are glad to
 notice a table which gives the means of estimating the
 relative frequency with which malignant disease attacks
 various parts or organs of the body. Malignant diseases in
 the aggregate is known to be more prevalent among women
 than among men, but it appears that the excess is largely
 due to the fact that the female generative and mammary
 organs are exceptionally liable to become affected. If
 the deaths from diseases of the ovaries, uterus, and
 breast be subtracted from the total cancer mortality
 the remaining deaths will give a mortality for females con-
 siderably lower than the male rate. In the year 1897, for
 example, the male deaths from cancer, less the deaths due
 to disease of the generative and mammary organs, gave a
 death rate equal to 625 per 1,000,000 living, whilst the
 female death rate similarly calculated did not exceed 551
 per 1,000,000. In addition to cancer of these organs
 malignant affections of the liver, peritoneum, intestines,
 kidney, and pelvis are exceptionally frequent among women,
 but men are more liable than women to cancerous disease
 of the larynx, trachea and lungs, and likewise of the
 mouth, tongue, throat, and oesophagus, as well as of the
 jaw, face, lip, and neck, and of the bladder and urethra.
 Of the 24,443 deaths referred to malignant disease during
 the year 1897 scirrhus accounted for 751, epithelioma for
 1289, and sarcoma for 1485, while the remaining deaths
 were returned as from cancer or malignant disease
 simply.

It is evident that the mortality in a given place from
 cancer is largely dependent on the proportion of persons
 under and over middle age in the population, since the
 mortality from this disease is mainly confined to persons
 over 35 years of age. The mean death rate from cancer
 during the last completed decennium per million persons
 living at all ages ranged from 440 in Durham, 475 in
 Staffordshire, 477 in Lancashire 482 in Derbyshire and in
 Monmouthshire and 501 in South Wales to 716 in Norfolk,
 727 in Sussex, 733 in North Wales, 740 in Devonshire, 789 in

IS THERE A RELATION BETWEEN THE IN-
 CREASE OF TYPHOID FEVER IN LONDON
 AND THE INCREASE OF ORGANIC
 MATTER IN THE WATER-SUPPLY?

This question, which has been raised recently by Dr
 Corfield, deserves very serious attention. In a special
 report to the parish of St George, Hanover square, he some
 time ago pointed out "that the exceptional prevalence of
 enteric fever in London during November, December
 and January, which are not the months for the seasonal
 prevalence of this disease, occurs in the very months
 in which London is supplied with water which contains
 'an excess of organic matter.'" Dr Corfield bases his
 contention on the statement contained in the report of
 Sir William Crookes and Professor Dewar "that all
 river-derived supplies have a period of minimum and
 maximum amount of organic matter during the course
 of the year. The maximum generally occurs in Thames
 water during the winter months and the minimum
 during the summer." This maximum is what Sir William
 Crookes and Professor Dewar describe as "an excess of
 organic matter." To this these experts attach no sig-
 nificance, for "it is common knowledge that if any
 such disease as enteric fever originates through a con-
 taminate water-supply it is not the amount of organic
 matter but its nature that is the dangerous factor
 and this must be the presence of the specific living
 germ characteristic of the disease. No one has alleged
 that Thames water which has undergone storage and filtra-
 tion similar to that of the London supply contains any such
 pathogenic organisms." Against this Dr Corfield quotes the
 experience of Sir Edward Frankland who has found an
 excessive number of organisms again and again in filtered
 Thames water, while Dr Parkes and Dr S Hideal have more
 recently found the bacillus coli communis passing in various
 numbers through the filter beds of the Chelsea Water-
 works Company. As to the bacillus of enteric fever it has
 rarely, Dr Corfield points out, if ever been found in
 any water supply, and on the occasion of the Maidstone
 epidemic Dr Washbourn said in his report that no
 importance can be attached to the failure to discover
 the typhoid bacillus in water suspected of being the
 cause of an epidemic of typhoid fever. The organisms
 which were found in the Maidstone water were of similar kinds to
 those found by Dr Parkes and Dr Hideal in the waters
 supplied to Chelsea. It seems to us that Dr Corfield has
 raised a very serious question, and his contention on the
 face of it appears to be supported by what he regards as a
 remarkable coincidence, that he was able last month to
 report that the number of cases of typhoid fever in London
 had very considerably diminished and the death rate from
 it gone down to its normal amount as soon as the water-
 supply had ceased to show the signs of contamination to
 which he has drawn attention.

THE HOME FOR THE UNIVERSITY OF LONDON.

It has for some time been quite understood that the
 Government intended to take over the present premises of
 the University of London to utilize them for its own pur-
 poses and that the reconstructed University would have to

Annotations.

"No gold mine."

1,000,000

find another home. The present premises are much too cramped and confined and rooms have had to be sought elsewhere for mere examination purposes alone. University College has offered the use of its buildings and site in Gower street, but the acceptance of this offer, even if the site and buildings were suitable, which is very much questioned, would have but little advantage and would much too closely identify one institution with the future University. King's College could not under its lease from the Crown offer its premises, although it is known that its Council is most anxious to facilitate any new arrangements. The only alternatives, therefore, before the University are a new and specially adapted building in a central position to be built by the Government, or its establishment at the Imperial Institute. It would appear from the speech of Lord James of Hereford on accepting the chairmanship of the Imperial Institute in succession to the late Lord Herschell that the question has been practically, if not definitely, settled. The Government will take over the Imperial Institute, as a preliminary step, in the name of the Crown. The University will be offered the east wing of the premises as tenants under the Crown and be quite independent of the Imperial Institute financially and otherwise. Considering that the present tenure of the building in Burlington-gardens is under the Crown and subject to very similar conditions there can be but little doubt as to the probable future. Lord Kimberley, Sir Henry Roscoe, and Sir Joshua Fitch are negotiating and are well aware that the Crown has every control over the existing institution. By the way, those interested in the welfare of London University must not think that the labours of its reconstitution are completed with the acquisition of a new home. A suitable site for central offices, good rooms for examination purposes, with proper laboratories for practical tests, especially in science, are very important, but the teaching university of London must not rest content with the provision of these facilities for education, leaving every and sundry school or college to go on the old lines depending on its own resources. The medical schools are very much more interested in questions affecting their status in the University and the aid which will be afforded to them by the University than in any secondary consideration as to where the University is for official purposes to be located.

HASHISH-SMOKING IN EGYPT

DR WARLOCK, who has been in charge of Egypt's solitary lunatic asylum for some years, regards the smoking of hashish as one of the most fertile causes of insanity in the country. In 1898 upwards of a third of his male patients were victims of the hashish habit, but apparently the same individuals were admitted more than once. Hashish is not produced anywhere in the Nile valley, the entire amount consumed finding its way into Egypt from Greece. Nominally the substance has long been contraband, but Lord Cromer says that prior to 1893 no very strenuous attempts were made to put the existing laws into force. The use of hashish either by smoking or in the form of a sweetmeat must be widespread among the Egyptians for last year no less than 12,000 kilogrammes of it were seized by the preventive services and presumably only a fraction of the total supply was captured. At 80 grammes per head, which amount is said to "meet the requirements of a confirmed smoker for a week," the above quantity would suffice for nearly 3000 habitual consumers during a twelvemonth. The coastguard agents are now very alert but they are comparatively few in number and to supervise effectively the frontier, which consists largely of sandy desert, is very difficult. The extreme portability of hashish renders it an easy article to smuggle and the greatest ingenuity is exhibited in concealing it. Amongst other un-
kely hiding places the narcotic extract has been discovered

in the hollow frames of iron bedsteads; inside specially prepared grindstones, and even in holes bored longitudinally through innocent-looking cask staves. In the Piræus hashish costs about 2½ 6d per pound, but owing to the "expenses of possible bribes and transport" the Egyptian retailers have to pay at least three times that sum. Last year Lord Cromer was of opinion that the best way of dealing with the hashish question was to admit the substance as a taxable commodity, but he is now in favour of partial prevention. In spite of the recent extensive seizures he does not believe that total exclusion will ever be practicable. "It is more than doubtful," he says, "whether the use of the drug can ever be entirely suppressed by preventive measures. The efforts of the coastguard to check the introduction and of the police to detect the presence of hashish in the interior may keep the price of the drug at a comparatively high figure and thus increase the difficulties of its acquisition by the population. More than this is scarcely to be expected." In this connexion it may perhaps be permissible to indicate a possible danger. Experience shows that in all communities there are people incurably addicted to narcotism in one form or another who will go to any lengths to procure the means of ministering to their appetite. Were hashish to be totally suppressed in Egypt the *hashash*, or habitual consumer, would inevitably seek far and near for a substitute, in alcohol perhaps or in some other narcotic of a still more deleterious character. Of two evils the less should be chosen, but then the difficulty often is to determine which that is. The abuse of hashish undoubtedly does cause insanity, although apparently the proportion of consumers whose mental equilibrium becomes disturbed is not a very large one. In 1898 the number of hashish patients at Abbasiyeh, where the whole of the pronounced lunatics in Egypt are interned, was only 133, or about 0.01 per 1000 of the total population. It would be well for England if the proportion of dipsomaniacs under restraint were no greater. In England the ratio of insane to population is 3.3 per 1000, but in Egypt it is only about 0.05 per 1000. Since hashish cannot be suppressed perhaps the wisest course would be to impose a heavy tax upon it while at the same time insisting on the maintenance of a fixed standard of purity. Badly prepared bhang or hashish is far more injurious than the properly elaborated extract, just as inferior whisky is more injurious than is a carefully matured spirit.

THE BACILLUS OF INFLUENZA.

In leading articles on Jan 14th and March 18th we referred to the clinical value of the bacillus of influenza. The diagnostic worth has not yet been fully investigated and, like the bacteriological corroboration of the diagnosis of diphtheria, is still doubted by some practitioners. In several instances the bacillus of diphtheria and the bacillus of influenza have been found at the same time in the throats of patients, and according to the report of the Department of Health of Chicago it would seem that a bacteriological diagnosis in influenza is of special advantage in detecting this disease when complicating other diseases. The bacilli had been found present not only in cases of diphtheria but also in cases of scarlet fever, measles, and pneumonia. In all these conditions it was noticed that there were clinical manifestations which were difficult to interpret until the microscopic examination was made. These "mixed infections" require further elucidation. Referring once more to the above-mentioned reports we find the following: "In the diagnosis of suspected diphtheria some interesting observations were made relative to obscure clinical symptoms of influenza. In cases which appeared at the onset to be diphtheria the presence of the *Coccus Pfeiffer* bacillus was demonstrated and the subsequent course of the disease confirmed the microscopic diagnosis of

and be happy. Be this as it may we should take note of the coroner's opinion and criticize less dependence on the State. There is far less excuse for such dependence than there was in the early days, and life, with all its competition, is infinitely richer and more varied and labour is better rewarded. But the business on which we set out was to congratulate the City Coroner on his jubilee and in heartily so doing we may add that Mr Langham was well acquainted with his brother coroner, the Founder of the THE LANCET, and is probably the only coroner now living who knew him personally

A NEW CLASSIFICATION OF MENTAL DISEASES

A sound and comprehensive classification of diseases is of the highest importance and in no department of medicine is this perhaps more needed than in the domain of mental diseases. In the last 20 years various schemes of classification have been propounded, among the more noteworthy being those of Magnan (France), Krafft-Ebing (Austria), Morelli (Italy), and the scheme of mental diseases adopted in the "Nomenclature of Diseases" of the Royal College of Physicians of London under Dr Hack Tuke and Dr Savage. In the *Journal of Mental Science* (April, 1899) Dr Lloyd Andreason, at the close of a lengthy contribution on the "Bases and Possibilities of a Scientific Psychology and Classification in Mental Diseases," propounds a classification of the insanities which is stated to be "based upon fundamental facts of evolution, upon deep seated effects of both ethnological and climatic import." This classification is said to be "a natural one and at the same time practically useful," and it is as follows. There are five main groups of insanity, and the words used to designate them explain themselves, viz—

1. *Sphincter*—Areas of cerebral (psychic) development, with a basis in the development of the motor, sensory, and intellectual functions of the brain, and in the development of the social and intellectual functions of the individual. These areas are characterized by a high degree of plasticity and by a high degree of development of the motor, sensory, and intellectual functions of the brain, and in the development of the social and intellectual functions of the individual. These areas are characterized by a high degree of plasticity and by a high degree of development of the motor, sensory, and intellectual functions of the brain, and in the development of the social and intellectual functions of the individual.

[illegible]

influenza. The report further states that in many of these cases the throat symptoms were so marked—redness and swelling of the tonsils and a well-developed membrane—that a diagnosis of subpharyngeal inflammation was made. On the other hand, found to be mild cases of diphtheria, although the clinical symptoms pointed strongly to influenza. It has been occasionally observed that when influenza was present in a household the eyes of some members of the family became acutely inflamed, accompanied by severe pain, swelling, and redness of the conjunctiva, with a profuse discharge of pus. Cultures were made from the discharges and the influenza organism was found to be present in large numbers. Since the publication of these reports we are informed that the Canon Pfeiffer bacillus has been identified in the bronchial mucus of a number of patients presenting the characteristic symptoms of mumps, especially as to glandular swelling, pain and effusion of the sterno-cleido-mastoid muscle, and rise of temperature. These symptoms have, however, not usually lasted more than three or four days the swelling and soreness then subsiding and the temperature becoming normal. Coincidentally with this subsidence of the parotidic symptoms there has in some cases occurred a sharp inter-nal distribution with, in two instances, parotitis and dysphagia. The variety of conditions with which the Canon Pfeiffer bacillus is found to be associated opens a large field for bacteriological investigation.

THE JUBILEE OF MR LANGHAM, THE CITY
CORONER

We venture to anticipate the jubilee of Mr Samuel R
 Langham in the work of the correspondence which will be
 attained on June 6th. It was on that day of 1849 that he
 was appointed Deputy Coroner for Westminster. He resigned
 this duty when he was appointed Coroner for the City of
 London. He also acts as Coroner for Southwark and in the
 Duchy of Lancaster district, which comprises the parish of
 Chatham. The special correspondent of the *Daily Chronicle*
 has had an interview with Mr Langham who is now
 76 years of age. Not unexpectedly has he attended
 as many as 14 inquests in one day. This is a prodigious
 and not very pleasant work but the coroner is bright
 and cheerful still. A man must indeed have a happy
 temperament who can be cheerful after 50 years of such
 work. Two very striking facts come out in the short
 account of the interview which should be stated in con-
 nection with each other. The coroners court is a gene-
 ral school for the study of life and of the estimate which
 men put upon life. The special correspondent was evidently
 anxious to get the coroners opinion as to the effect of
 the social and political changes of the last half century. The
 greatest of which, perhaps is the tendency of the State to
 assume more and more responsibility for the individual. Mr
 Langham was not to be drawn into a full answer to that big
 question, but he made one thing clear to the correspondent—
 in his opinion "people are growing more careless of their
 lives. They are getting reckless" have the Parisians and do
 not hesitate about throwing themselves away." He went on
 to attribute this to the greater pressure and competition of
 life. Perhaps it is partly so but it is worth while con-
 sidering whether we are no somewhat impaired in moral
 tone in paying so much Sane care. William Cobbett—
 whose son was an early friend of Mr Langham—who was so
 fond of the French motto "vivre de peu", would have
 accounted not with but knowledge and a certain strong
 independence of spirit which records the open which to live

(1) vesanic type (e.g., melancholia, mania, stupor, acute mental confusion, and asthenic confusion), (2) toxic type (e.g., alcoholic delirium tremens, mania à potu, chronic alcoholic insanity, lead encephalopathy, morphinism, cocaineism, ergotism, and pellagra), (3) febrile micro-parasitic type (e.g., some puerperal insanities, delirium acutum, and the grave delirium of influenza, scarlet fever, acute cerebral meningitis, tuberculous meningitis, &c.), (4) diathetic group (e.g., myxoedematous, goitrous, acromegalic and possibly diabetic insanity, post syphilitic pseudo paresis, &c.), (5) chronic meningo-encephalitis of progressive type (e.g., general paralysis of the insane), (6) involuntional type (e.g., climacteric insanity and the chronic cerebral atrophy and senile insanity of middle and old age), (7) traumatic type (e.g., the "cérébraux" of Lasague), and (8) neoplastic and thrombotic type (e.g., of cerebral softenings, gliomata and other neoplasms, &c.)

5 *Lypophrenia*—Terminal conditions of mental dissolution secondary to previous insanities. These comprise many and varied types and groups with different antecedents but with one terminus and goal to which they all tend

The basis of the above classification is the principle that abnormalities (morbid changes and alterations) may and do occur "at all stages in the evolution of the brain and of its function, from the foetal (vegetative, somnolescent) to the sexually mature (adolescent) stage," with corresponding variations in the evolution of personality, of bodily conformation and appearance, and of conduct and capacity for intellectual, social, and ethical life. Thus studied it is found that the insanities fall into five groups which assume a serial and tree-like arrangement. At the lower end of the series, where hereditary foetal and intrinsic vice of organisation preponderates, we find Groups (1) and (2)—viz., the profound arrests (*aphrenia*, idiocy) and enfeeblements (*oligophrenia*, imbecility) of cerebro-psychical development. At the other end of the scale are grouped the morbid conditions which affect brains of nearly full cerebro-psychical development and of apparent previous health. These comprise the various types and classes of the *phrenopathies*, Group (4). Between these extremes comes a "degenerative" group with anomalies of evolution in the sense alluded to and classified under *paraphrenia*—i.e., Group (3). Fifth and last comes the group which includes the wrecks and remnants of previous mental disease, "chronic derelicts after storms, deprived of their mental equipments and reduced to low grades and levels of mental life—a highly motley, artificial, and lumber room group really—the chronic demented." These constitute the terminal Group (5) which for uniformity of nomenclature is termed *lypophrenia*. It will be seen from the details given above that while some of the groups are sharply marked out others constitute grades and types having close affinities with allied groups and that some types must of necessity overlap or blend with others, as indeed is found in practice to be the case, and, finally, it must be borne in mind that occasionally mixed types may occur—i.e., in which two or more mental morbid conditions may co-exist as combined morbid conditions exist in other parts or organs of the body

THE DANGERS OF CHEMICAL TRADES

THE locked up energy in certain chemicals must always be a possible source of danger to the workers concerned in their elaboration. The disaster at St Helens, Lancashire, on May 12th was essentially one arising from chemical manufacture, though the cause of the frightful explosion which occurred and by which several persons met a ghastly death is not easy to account for. All that can be said is that the explosion had its origin in the tank where chlorate of potash was being crystallised on a large scale. The tank was observed to be on fire which rapidly extended to the storehouse. Chlorate of potash is, of course, not *per se* combustible, but it is a powerful aid to combustion under some circumstances by reason of the readiness with

which it parts with its oxygen. Alone, the greatest possible mass of chlorate of potash would be quite harmless. What, then, was the combustible matter in the chlorate crystallising house which subsequently led to a disastrous explosion? If by any chance sulphuric acid had reached the shed the highly explosive compound chlorine peroxide would have been evolved, but there is no evidence on this point. The force of the explosion liberated some quarter of a million cubic feet of coal gas in the neighbouring gasholders which caught fire and burnt with considerable energy. At the same time tanks containing vitriol were destroyed and tons of this corrosive fluid streamed down the streets to the sewers. It is difficult, therefore, to calculate the extent of the mischief. Doubtless some light will be thrown on the disaster at the inquest which was adjourned on May 15th until May 30th.

COINCIDENCES IN HOSPITAL PRACTICE.

IN THE LANCET of May 13th we published an article by Dr F. J. Smith, Mr O. Mansell Moullin, and Dr Arthur Keith, on two very rare forms of hernia which came under observation at the London Hospital within six weeks of each other. This week in our "Mirror of Hospital Practice" our readers will find an account by Mr Frederec Eve and Mr J. McCarthy, with pathological notes by Mr H. L. Barnard, of two cases of filariasis which were admitted consecutively into the same bed in the same hospital (the London Hospital), and all medical men connected with hospitals know the strange frequency with which these coincidences occur, and probably every member of the staff of any large hospital will be able to recall similar occurrences both in the wards and in the out-patient rooms—two cases of actinomycosis admitted within a day of each other, two cases of plastic bronchitis coming to the out-patient room within the same week, &c. In short, the doctrines of chance seem to be regularly defied in hospital practice.

PLUMBISM MISTAKEN FOR APPENDICITIS AND OTHER ABDOMINAL CONDITIONS

IN the *Journal of the American Medical Association* of April 15th Dr J. P. Lord has published the following case. He was asked by the physician in attendance to see a case of appendicitis which had been admitted to hospital. The patient was a corpulent man, aged 28 years, with a fat, prominent abdomen. He was somnolent and delirious. There were constant vomiting, pain and tenderness chiefly somewhat internal to McBurney's point, board-like rigidity of the whole abdomen, and general tympanites except over an area of the site of the palm just internal to the normal position of the appendix, where there was an indistinct doughy mass, dull on percussion. The patient had been constipated for five days and was in a serious condition and getting weaker. A previous attack had occurred. Laparotomy was therefore immediately performed by the McBurney incision. A long appendix free from adhesions was removed. It was healthy, though it was thickened, and contained two small faecal concretions. The caecum and ascending part of the ileum were distended and congested. Exploration revealed a mass of ileum and jejunum contracted to the diameter of the little finger. The caecum was punctured by a trocar to allow gas to escape and a solution of Rochelle salts was injected. The patient began to improve after the bowels acted some hours later. Dr Lord remarked that the only similar case which he had seen was in a man in whom plumbism was discovered after operation. He then was told that the patient whose case has been described had been a plumber. A well marked blue line was found on the gums. The man had not worked at his trade for four years but he was a barman and the beer which he drew and also drank

passed through about 10 feet of leaden pipe. In the other case referred to by Dr Lord, the diagnosis as obscure. The patient insisted that the contents of the bowels were arrested at the painful point—the splenic flexure of the colon—and demanded operation. All that was found was a constriction of the colon for about 4 inches at the splenic flexure, the gut being reduced to the size of a finger. Plumbism was only discovered afterwards. Literature for the most part is full of "System of Medicine," that in animals he has found the small intestine irregularly contracted, at places so extreme was the spasm that the intestines felt like a piece of cord its calibre being obliterated. In the *Journal of the American Medical Association* of Jan 4th and 11th 1896, Dr J. B. Murphy also has described a case in which obstructive symptoms occurred in a subject of plumbism. The abdomen became greatly distended and catarrhs and infections were relieved to relieve the constipation. The medical attendants believed that the condition differed materially from previous attacks of lead colic which the patient had had. An enlarged coil of intestine could be seen leading up to the right hypochondrial region. Laparotomy was performed. The enlarged coil was found to terminate in a contracted portion which resembled a solid cord three-eighths of an inch in diameter. At first it was believed to be an organic stricture. But after about 10 minutes' exposure to the air the spasm subsided and the intestine dilated. Recovery ensued.

THE NATIONAL ANTI-VIVISECTION SOCIETY

The annual public meeting of the National Anti Vivisection Society held at St James's Hall is described as having been an enormous gathering and the speeches reported as having been delivered appear to have been worthy of the occasion. Without criticising them at length we note with interest the way in which each of the principal speakers approached the question from his personal or professional point of view and we venture to express a doubt whether in each case he would secure the undivided support of those addicted to the same pursuits or members of the same profession. For example, the Duke of Portland, with whose views of the national value of sport to England and Englishmen we agree, found himself led on to say, if he is correctly reported, that "the object of the sportsman was to kill his quarry out-right with as little pain as possible." The most enthusiastic sportsman would hardly contend that to run a fox into the next county (and perhaps have to leave it at large to die from exhaustion) is to kill it with as little pain as possible. Again, Lord Coleridge, Q.C., naturally used legal phrases and talked of "a very careful investigation of the facts" after which "he entirely disbelieved the statement that vivisection led to discoveries which tended to alleviate human suffering." We confess that we should like to hear his lordship cross-examined by one of his learned friends in order to ascertain the precise evidence upon which he relied in his investigation and the precise quality of the judicial report in which he approached it. Canon Wilberforce in his turn, "stood on the side of St Paul and believed that the lives of animals were bound to our own by a mysterious solidarity which we were at present unable to realise" that in the great eternal world we (i.e. men and animals) should sink or swim together. He would rather enter into a Nixiana with some dogs he had known than he would go into a narrow saloon with some so-called religiousists. "We can only leave Canon Wilberforce to theologians for criticism and comprehension. Mr force to theologians for criticism and comprehension. Mr

It is stated that the Government's proposals in regard to amended legislation on the storage and sale of petroleum have at length been drafted in a Bill. It would appear that the regulations as to sale and storage which now apply to petroleum with a flash point under 73° F. are to be maintained, but less stringent regulations of a similar character will in all probability be applied to petroleum having a flash point of between 73° and 85°. The new measure would seem, therefore, to provide less stringent regulations for the storage of the oil but would place more control over the sale and use of oil of a definite flash point.

A NEW PETROLEUM BILL

MISS CONSTANCE INYAT last week sent to the *Times* extracts from a letter written by Miss Dunford of the University Mission to Central Africa giving a terrible account of the suffering of the people from plague and famine in the neighbourhood of Magilla, Boude, East Africa. The Foreign Office is making inquiries into the case and it is to be hoped that it will send some relief. Any who are disposed to help should send contributions to the secretary, Universities Mission to Central Africa, 9, Dartmouth street, Westminster, S.W.

THE FAMINE IN EAST AFRICA

Stephen Colledge at least adhered to the one national standard-point open to him in declaring his view that to lengthen human life, if so doing implied the infliction of pain on animals, was unjustifiable and morally wrong. This is an opinion which everyone is entitled to hold if he or she will consistently act upon it in sickness as well as in health.

THE PHYSIOLOGICAL ACTION OF CHOLINE AND NEURINE

In a paper recently (April 20th) read before the Royal Society Dr F. W. Mott and Dr W. D. Halliburton, the writers, gave the results of experiments made on anaesthetised animals which showed that the cerebro-spinal fluid removed sometimes after death and sometimes by lumbar puncture during life from cases of brain atrophy, and especially from patients suffering from general paralysis of the insane, caused when injected into the vessels a fall of arterial pressure with but a trivial effect on the respiration. Chemical examination of the fluid proved that it contained nucleo-proteid and choline and further experiments demonstrated that the effect on the circulation was due to the choline. The composition of choline given by Waller is $C_4H_{11}NO$. It is closely related to, but is not identical with neurine. The crystals of the platinium double salt when crystallised from 15 per cent. alcohol are characterised by octahedra. There is every reason to believe that choline precedes, like the nucleo-proteid, from the acute disintegration of brain tissue. The writers of the paper think that some, but not all, of the symptoms of general paralysis are due to auto-intoxication, nucleo-proteid and choline contained in the cerebro-spinal fluid being absorbed into the blood. In accordance with this they have found choline in the blood of general paralytic patients drawn by venesection. When from one to 10 cubic centimetres of solutions of choline containing two parts in 1000 were injected into the vessels a temporary fall of blood pressure occurred, due in part to its action on the heart but chiefly to dilatation of the peripheral vessels of the internal area. This effect is attributable to the direct action of the base on the neuro-muscular mechanism of the blood vessels themselves for the reduction of pressure still continued to occur after removal of the spinal cord. Choline has little or no action on the nerve trunks as tested by their electrical response to stimulation. In

cagard to, neurine, which has the formula $C_8H_{11}NO_2$ it was found that intravenous injection of from one to five cubic centimetres of a solution containing one part to 1000 caused a fall of arterial pressure followed by a marked rise and a subsequent fall to the normal level. The fall in the first instance is due to slowing and weakening of the heart's action with possibly a dilating influence on the peripheral vessels. The secondary rise in the blood pressure is due to the constriction of the peripheral vessels, as shown by oncometers applied to the intestine, spleen, and kidney. The typical effects of neurine are still obvious after removal of the influence of the central nervous system by section of the spinal cord or of the splanchnics. After, however, the action of the peripheral ganglia has been cut off by the use of nicotine neurine produces only a fall of blood pressure. It hence appears that the constriction of the vessels is due to the action of the drug on the ganglia. Section of the vagi had no influence on the results of injecting either choline or neurine and there was no evidence that either base acted directly on the cerebral vessels. Unlike choline, neurine is intensely toxic to nerve trunks. The writers confirm the statement of Cervello that neurine acts like curare on the nerve endings of voluntary muscle and that the cessation of respiration is due to this action.

A FRENCH VIEW OF FRENCH ALCOHOLISM

NOT the least of the many evils affecting France is her consumption of alcohol. It is known that the honest glass of light wine which used to meet the wants of the ordinary Frenchman is now supplemented with spirit in all forms and that France is first of all countries in the amount of alcohol which is consumed. The only hopeful thing about the fact is that Frenchmen are beginning to perceive it and its grave significance. The *Figaro* is devoting a series of papers to the discussion of the question and to a statement of the disastrous effects which are already apparent in the French population. The second of these papers is before us and no teetotal newspaper in England could give more convincing figures or testify more faithfully to the degradation, physical and moral, which overtakes the communities which are distinguished by their excess. The one set-off in theory is that the substitution of stronger drinks for lighter ones produces temporary satisfaction—a merry life if a short one. Instead of this a general depression, a melancholic tendency, is the effect, and life is "short and horrible." The drinkers are morose and suicidal in the direct ratio of the alcohol taken. In the years from 1861 to 1865 there entered the asylums of France 14,983 insane persons, in the same space of time twenty years after there entered more than 57,000. Dr Serieux has made researches on this point as to the rôle of alcohol and he has found that of the relapsed cases (*répétivistes*) 78 per cent were drinkers, while of violent maniacs 88 per cent were drinkers. Short of insanity the morale of the French workman is rapidly deteriorating under the influence of alcohol. He loses his ambition and goes down from a master worker to a labourer. The degeneration affects whole families, especially in Normandy. An instance is given of a family which had occupied a mill for two generations. At first they were giants (*colosses*), now the grandchildren are dwarfs and stunted. They are without any desire to be raised again and prefer to be servants. In some parts the drinking is incredible, thus the peasants in the neighbourhood of Flers and Falaise "have the glory of having arrived at the consumption of *un litre d'eau de vie de cidre par jour*," or 365 litres per year. In Normandy the women are as bad as the men and the infants are getting *eau de vie* in all their food. What strikes the writer in the *Figaro* is that while other nations are alarmed and are making efforts to

overcome this terrible agent France is drinking more and more. He quotes encouraging facts as to the success of such efforts. In Sweden, e.g., the race threatened to be extinguished by a consumption in 1829 of 23 litres per head per annum, they set themselves strenuously to resist and have brought the consumption down to 3.2 litres. So in other countries. The patriotic writer says "Shall we leave France to her fate without an attempt to save her?" and answers with a thousand Noes. We have too big a beam in our own eye to moralise on the state of France, but we rejoice that this gigantic evil is being recognised by Frenchmen and we heartily hope for the victory of France over one of her greatest enemies.

ANNUAL ORATION AND CONVERSAZIONE AT THE MEDICAL SOCIETY OF LONDON

THE annual oration of the Medical Society of London was delivered at the society's home in Chandos-street on May 15th and was listened to by a very large number of members and guests who were received by the President, Mr Edmund Owen. The oration was delivered by Mr Alban Doran on Shakespeare and the Medical Society and was a very brilliant performance. A vote of thanks was proposed by Dr Thorowgood, seconded by Sir William Dalby, and carried by acclamation. Subsequently a conversazione was held in the rooms which were crowded till a late hour. Excellent music was provided by the Bijou Orchestra and a most enjoyable evening was spent, thanks to the careful arrangements made by the honorary secretaries, Dr Calvert and Mr Battle, and the registrar, Mr W. R. Hall.

PHLEGMASIA DOLENS IN TYPHOID FEVER

PHLEGMASIA dolens is rare in typhoid fever, Murchison estimated its incidence as 1 per cent. In an interesting lecture published in the *Boston Medical and Surgical Journal* of March 23rd Dr Da Costa states that among 215 cases of typhoid fever in soldiers admitted into the Pennsylvania Hospital phlegmasia dolens occurred in no less than 30, or 14 per cent. The general proportion of cases with this complication in the hospital is not more than 1 or 2 per cent. In 18 cases under the care of Dr Da Costa the left leg was affected in three, the right in two, and both legs in 13. He explains the frequency of the complication in soldiers by predisposition from distension of the veins of the legs by marching. But excepting some from Porto Rico most of the soldiers came from training camps where marching was not excessive though more than men just come from civil life were accustomed to. The gravity of the infection also was important, for nearly all the cases occurred in those in whom the fever had been severe. This complication occurred mostly at the end of the fever or during convalescence. The earliest symptoms are increased temperature and pain in the limb. Chills sometimes precede it. The pain is usually associated with tenderness which first shows itself in the calf. Swelling is generally obvious, especially below the knee. The limb is tense and hard though there may be some pitting around the ankles and calf. The skin is pale or white, but here and there an erythematous blotch or even a small ulcer is seen. The veins may be prominent or not, tender or not. Those most usually affected are the internal saphenous and femoral, especially at their junction, sometimes the affection extends to the iliac veins and even to the vena cava. As to the pathology Dr Da Costa regards the complication as primarily thrombosis which afterwards may or may not be complicated by phlebitis or periphlebitis. As a rule the thrombus gradually disappears without serious symptoms and the phlebitis if present slowly yields, or a adhesive inflammation results and a collateral venous circulation is established. But cases have been recorded

are developing the international aspect of their society and that Dr. Salter, the Professor of Hygiene in the University of Amsterdam and Foreign Secretary of the Epidemiological Society of London for Holland and Belgium, is to deliver an address at the rooms of the Medical Society, 11, Chandos street, Cavendish square, W., at 8.30 p.m. on Friday, May 19th. Professor Salter has selected for the title of his paper "A Study of Enteric Fever in the Netherlands," and as the address is, we hear, to be delivered in English, a language which Professor Salter speaks quite fluently, an interesting discussion may be looked forward to. It is probable that but few of the members of the society are so familiar with Dutch as to be able to debate in it.

ELEMENTARY CHEMISTRY

It is remarkable, when elementary chemistry is re-investigated under the conditions afforded by the increased facilities of modern times, what interesting results are obtained. Chemists would seem to have been spellbound by the interesting possibilities opened up by the pursuit of the organic section of the science, taking the rudiments as granted and established long ago. But if these investigators could be induced to leave the alluring and fascinating field of organic research in favour of elementary inorganic work the results would be equally interesting and probably equally, if not more, important in strengthening the substance of the science. At the last meeting of the Chemical Society Professor Harold B. Dixon detailed the results of some simple experiments and they proved interesting. Thus, in dealing with the combustion of carbon disulphide he found that the vapour undergoes a phosphorescent combustion, in air similar to that of phosphorus and sulphur. In the combustion of carbon disulphide, in spite of the presence of an excess of oxygen, small quantities of unaltered carbon remain. In another paper Professor Dixon showed that in the combustion of carbon dioxide is due to a single and direct action between carbon and oxygen. It has been accepted that the carbon monoxide is only formed by a secondary action between carbon dioxide and carbon. On the other hand, experiments would seem to make it very probable that in the combustion of carbon the incomplete product carbon monoxide is first formed. This should throw some light on the conditions ensuring the perfect combustion of coal and coal gas and thus directly affect the question of smoke abatement. It is now well known, further, that in the products of the spontaneous oxidation of coal at ordinary temperatures deadly carbon monoxide occurs which would injuriously affect the health of miners.

TUBERCLE OF THE TESTICLE IN CHILDHOOD.

The Journal de Clinique et de Thérapeutique Infantile of May 4th contains a report of M. Félizet's observations on 58 cases of tubercle of the testicle almost invariably attacks these organs in children under seven years of age. As in adults, the epididymitis is by far its most usual place of origin the cord is less often invaded, the frequency of Hydrocele seminaries, and the bladder still less frequently. Hydrocele is rarely present and the course of the disease, as might be expected in tissues which are virally embryonic is often rapid, infection proceeding not only by the spermatic ducts, vesicles but by the inguino-thoracic lymphatics also. M. Félizet is not an uncompromising advocate for castration as a remedy but is disposed up to a certain point to rely on hygienic and medicinal measures. Even when there is adhesion of the testicle to the scrotum and subsequent abscess formation

in a case which pyæmia or fatal embolism occurred. Recovery from embolism, Gangrene, is an occasional result. Recovery is slow and the leg may remain swollen for months and readily become so after exercise. The dilated superficial veins may show how much the circulation has been interfered with, and adhesive, inflammation may leave the apheous or femoral vein hard and cord like. The treatment consists in elevating the leg to assist the circulation and in applying heat and bandaging to relieve the pain and in applying heat and bandaging to relieve the pain and in applying heat and bandaging to relieve the pain. The most relief Constipation, if present, must be treated. If the pain is persistent belladonna plaster in strips or belladonna ointment applied along the vein is often useful. When the patient leaves his bed the limb should be well bandaged which must be continued, or an elastic stocking must be used, for a long time until the veins recover their tone and until symptoms of obstruction have disappeared.

LIFE TABLES

At a meeting of the Royal Statistical Society held on May 16th in the Lecture Theatre of the Royal United Service Institution, a paper was read by Mr. T. E. Hayward, medical officer of health of Haydock, Lancashire, "On Life Tables, their Construction and Practical Uses." Allusion was first made by Mr. Hayward to the relative importance of vital statistics as compared with other subjects from time to time brought before the society and the special value of life tables was emphasized. A life table was then defined as a scientific instrument designed for exactly measuring the forces of life and death prevailing, whether among a whole nation or in the separate communities which constitute the nation, and it was pointed out that only by the use of life tables was it possible for exact comparisons to be made in these respects. Mr. Hayward had as his primary object in preparing the paper the desire to aid his brother medical officers of health in compiling what had been regarded as a very abstruse and difficult matter and thus to promote the more general working out of local life tables for the various sanitary districts in which the country is divided. Special emphasis was laid upon the fact that no very profound mathematical knowledge is required for this work, the only equipment needed being a working knowledge of the use of seven logarithms and some patience in applying the ordinary rules of arithmetic and the endeavour would be made so fully to explain the subject that the plain man need not err therein.

INTERNATIONAL EPIDEMIOLOGY

The geographical distribution of disease is a subject concerning which we know considerably more than of the laws which govern such distribution, and, unfortunately for the study of these laws, diseases, whether endemic or epidemic, are no respecters of international boundaries or scientific frontiers, unless, indeed, such frontiers happen in any case to be continuous with the natural limitations of any given disease. While therefore this condition of affairs obtains we must be content to study the behaviour of the disease by making use of the facilities which national statistics and administrative efforts, and by the comparison of the results and impressions obtained in one nation with those obtained in others. Doubtless had there been a universal language for greater progress would have been made in this direction than had been the case up to the present, and it is to be feared that until the English develop greater linguistic resources some of the good work done by workers in European countries other than France and Germany must remain but imperfectly appreciated. We are glad, however, to see that the Epidemiological Society of London

he is content to employ local conservative methods. When, however, in addition to suppuration there are present the signs of general impairment of health he advocates immediate removal of the gland as the only means of preventing a very rapidly fatal form of general tuberculosis. Unfortunately, we are not informed of the results obtained by treatment in these 53 cases. If they should hereafter be forthcoming they ought materially to aid a decision as to the true indications for castration in the infantile variety of this disease. M. Felizet contends that the condition of rapid tissue development is not favourable to the resistance of an infective process and in that case the stage of hygienic treatment and local conservative surgery must be a period of watchful care and not be too prolonged. Many authorities consider that in the adult excision of the testicle offers the best hope of cure and we are still in want of proof to show that the case of children is materially different.

TUNG WAH HOSPITAL, HONG-KONG

IN the report of the Hong Kong Medical Department for 1897 several pages are devoted to the Tung Wah Hospital. Dr J. M. Atkinson, the principal civilian medical officer of the colony, considers that the existence of this institution in which more than four fifths of the inmates are treated by so-called Chinese methods is somewhat anomalous in a British colony. Without discussing the expediency of humouring the prejudices of the Chinese population, who outnumber the Europeans by 20 to one, he is of opinion that from a medical point of view the hospital ought to be abolished, although he admits that it serves a useful purpose as an asylum for destitutes and a resting place for the dying. The medical staff have no knowledge of surgical treatment and no instruments, pitch plaster is their panacea for all surgical injuries and diseases, and they never administer chloroform. Once in 1895 when Dr Atkinson showed them the relief which a catheter gave to a patient suffering agones from distension of the bladder they smiled and seemed highly amused, but it did not occur to them that such knowledge would be useful. The patients are mostly poor people of the artisan class, coolies, &c., all of whom have a dread of the foreigner and his methods. Treatment on European principles carried out by a Chinaman, Dr Chung, may be had by those who desire it, and it is the practice for the head coolie to ask the patients at the time of admission which system they prefer. Dr Atkinson considers that the indigent Chinese should be treated according to European methods in a hospital under the direct supervision of the Colonial surgeon in charge, the Asiatic medical staff being employed only as dressers, a course for which there is a precedent in the Tse Tock Seng Hospital at Singapore, where the great majority of the patients are Chinese. An appendix to Dr Atkinson's report contains a statement of the work done by Mr Frank Browne, F.C.S., in the Government laboratory. There were five cases of datura poisoning investigated during 1897, all of them being with criminal intent. All the patients recovered. The mydriatic principle of datura was isolated from their urine without difficulty.

SANITATION IN EDINBURGH

WE have received a copy of the annual report of the chief sanitary and market inspector of the city of Edinburgh (Dr A. M. Williamson) for the year 1898 from which it would appear that distinct sanitary progress is being made. The sanitary supervision of the city is being extended, and to carry this out more satisfactorily the city has been divided into wards, and for this purpose the services of nine inspectors have been retained to make a door-to-door inspection 'in quest of conditions of an insanitary nature.'

Four other inspectors devote their time to dairy, baby-house, and lodging house inspection and the carrying out of the provisions of the Factory and Workshops Act, the Shop Hours Act, and the Food and Drugs Acts. The report is illustrated with some excellent and instructive diagrams on the relation of overcrowding, &c., to the public health. Under the Food and Drugs Acts 50 per cent. of the articles secured were of doubtful quality, milk and butter being the subjects most liable to adulteration. Under the Margarine Act seven prosecutions were instituted and a conviction followed in each case. Dr Williamson points out that a great laxity exists in carrying out the provisions of this Act. An excellent look out is kept in the city to exclude as far as possible the sale of tainted meat. Under the heading of tuberculosis Dr Williamson makes one important remark which applies, we feel sure, to other cities in the kingdom. "Every byre in the city," he says, "is regularly inspected once a fortnight, and in this manner the slightest indication of a commencing disease of this dangerous nature is at once detected." "The importance of extending the system of inspection," he adds, "to those country byres which contribute supplies of milk to the city is accentuated by an inquiry which I have recently instituted as to the source of the whole of our milk supply. This inquiry disclosed that while the daily consumption of sweet milk amounts to nearly 13,000 gallons, between 7000 and 8000 of these—i.e., more than half—are received from districts to which our inspection does not extend." This section of the report is accompanied by an excellent plate showing the microscopical appearance of tuberculous milk.

THE ROYAL BRITISH NURSES ASSOCIATION.

THE *café chantant* presided over by H.R.H. the Princess Christian at the Hotel Cecil on May 15th was a great success. Both afternoon and evening the rooms were filled with an audience which will probably mark the occasion as one of the principal events of the season. Amongst those who, in addition to the Royal President, honoured the entertainment with their presence were the Prince of Wales, Prince Christian, the Duchess of York, the Duchess of Connaught, Princess Henry of Battenberg, Princess Victoria, the Duke and Duchess of Devonshire, and the Duchess of Marlborough. The practical manner in which the assembly showed appreciation of the association and its objects should do much to place it on a permanent basis. The object is to further everything which appertains to nursing. Unfortunately its work has been greatly retarded by internal dissensions. Now, however, these have been overcome and it is to be hoped that many prominent matrons and others holding high positions in the nursing world who formerly refused to support the association will now withdraw their opposition and join its council in its efforts to sustain the honour of its members. Amongst its many endeavours is one which will appeal to everyone—namely, the establishment of an endowment fund to provide for nurses who from age or physical infirmity are unable to carry on their duties. The substantial sum which the *café chantant* must produce will materially benefit this special fund. The programme must have satisfied the most critical. Recitations, songs, and dramatic interludes followed each other in rapid and varied succession. The theatres sent a strong contingent of well known artists, such as Lady Bancroft, Mr Charles Wyndham, Mr H. B. Irving, Mr Louis Calvert, Miss Esmé Beringer, Miss Mabel Lewis Terry, Mr Cyril Maude, Mrs Tree, and many others no less celebrated, while the opera and concert hall were represented by Mr Joseph Hollman, Miss Marian Mackenzie, Miss Giulia Ravogli, Madame Alice Gomez, Miss Clara Butt, Vladimir de Pachmann, Johannes Wolff, and Madame Norcross. The highest praise

he is content to employ local conservative methods. When, however, in addition to suppuration there are present the signs of general impairment of health he advocates immediate removal of the gland as the only means of preventing a very rapidly fatal form of general tuberculosis. Unfortunately, we are not informed of the results obtained by treatment in these 58 cases. If they should hereafter be forthcoming they ought materially to aid a decision as to the true indications for castration in the infantile variety of this disease. M. Felizet contends that the condition of rapid tissue development is not favourable to the resistance of an infective process and in that case the stage of hygienic treatment and local conservative surgery must be a period of watchful care and not be too prolonged. Many authorities consider that in the adult excision of the testicle offers the best hope of cure and we are still in want of proof to show that the case of children is materially different.

TUNG WAH HOSPITAL, HONG-KONG

IN the report of the Hong Kong Medical Department for 1897 several pages are devoted to the Tung Wah Hospital. Dr J. M. Atkinson, the principal civilian medical officer of the colony, considers that the existence of this institution in which more than four fifths of the inmates are treated by so-called Chinese methods is somewhat anomalous in a British colony. Without discussing the expediency of humouring the prejudices of the Chinese population, who outnumber the Europeans by 20 to one, he is of opinion that from a medical point of view the hospital ought to be abolished, although he admits that it serves a useful purpose as an asylum for destitutes and a resting place for the dying. The medical staff have no knowledge of surgical treatment and no instruments, pitch plaster is their panacea for all surgical injuries and diseases, and they never administer chloroform. Once in 1895 when Dr Atkinson showed them the relief which a catheter gave to a patient suffering agonies from distension of the bladder they smiled and seemed highly amused, but it did not occur to them that such knowledge would be useful. The patients are mostly poor people of the artisan class, coolies, &c., all of whom have a dread of the foreigner and his methods. Treatment on European principles carried out by a Chinaman, Dr Chung, may be had by those who desire it, and it is the practice for the head coolie to ask the patients at the time of admission which system they prefer. Dr Atkinson considers that the indigent Chinese should be treated according to European methods in a hospital under the direct supervision of the Colonial surgeon in charge, the Asiatic medical staff being employed only as dressers, a course for which there is a precedent in the Tan Tock Seng Hospital at Singapore, where the great majority of the patients are Chinese. An appendix to Dr Atkinson's report contains a statement of the work done by Mr Frank Browne, F.O.S., in the Government laboratory. There were five cases of datura poisoning investigated during 1897, all of them being with criminal intent. All the patients recovered. The mydriatic principle of datura was isolated from their urine without difficulty.

SANITATION IN EDINBURGH

WE have received a copy of the annual report of the chief sanitary and market inspector of the city of Edinburgh (Dr A. M. Williamson) for the year 1898, from which it would appear that distinct sanitary progress is being made. The sanitary supervision of the city is being extended, and to carry this out more satisfactorily the city has been divided into wards, and for this purpose the services of nine inspectors have been retained to make a door-to-door inspection 'in quest of conditions of an insanitary nature.'

Four other inspectors devote their time to dairy, baby-house, and lodging house inspection and the carrying out of the provisions of the Factory and Workshops Act, the Shop Hours Act, and the Food and Drugs Acts. The report is illustrated with some excellent and instructive diagrams on the relation of overcrowding, &c., to the public health. Under the Food and Drugs Acts 50 per cent of the articles secured were of doubtful quality, milk and butter being the subjects most liable to adulteration. Under the Margarine Act seven prosecutions were instituted and a conviction followed in each case. Dr Williamson points out that a great laxity exists in carrying out the provisions of this Act. An excellent look out is kept in the city to exclude as far as possible the sale of tainted meat. Under the heading of tuberculosis Dr Williamson makes one important remark which applies, we feel sure, to other cities in the kingdom. "Every byre in the city," he says, "is regularly inspected once a fortnight, and in this manner the slightest indication of a commencing disease of this dangerous nature is at once detected." "The importance of extending the system of inspection," he adds, "to those country byres which contribute supplies of milk to the city is accentuated by an inquiry which I have recently instituted as to the source of the whole of our milk supply. This inquiry disclosed that while the daily consumption of sweet milk amounts to nearly 13,000 gallons, between 7000 and 8000 of these—i.e., more than half—are received from districts to which our inspection does not extend." This section of the report is accompanied by an excellent plate showing the microscopical appearance of tuberculous milk.

THE ROYAL BRITISH NURSES ASSOCIATION

THE *café chantant* presided over by H.R.H. the Princess Christian at the Hotel Cecil on May 15th was a great success. Both afternoon and evening the rooms were filled with an audience which will probably mark the occasion as one of the principal events of the season. Amongst those who, in addition to the Royal President, honoured the entertainment with their presence were the Prince of Wales, Prince Christian, the Duchess of York, the Duchess of Connaught, Princess Henry of Battenberg, Princess Victoria, the Duke and Duchess of Devonshire, and the Duchess of Marlborough. The practical manner in which the assembly showed appreciation of the association and its objects should do much to place it on a permanent basis. The object is to further everything which appertains to nursing. Unfortunately its work has been greatly retarded by internal dissensions. Now, however, these have been overcome and it is to be hoped that many prominent matrons and others holding high positions in the nursing world who formerly refused to support the association will now withdraw their opposition and join its council in its efforts to sustain the honour of its members. Amongst its many endeavours is one which will appeal to everyone—namely, the establishment of an endowment fund to provide for nurses who from age or physical infirmity are unable to carry on their duties. The substantial sum which the *café chantant* must produce will materially benefit this special fund. The programme must have satisfied the most critical. Recitations, songs, and varied successes ludes followed each other in rapid and varied succession. The theatres sent a strong contingent of well known artists, such as Lady Bancroft, Mr Charles Wyndham, Mr H. R. Irving, Mr Louis Calvert, Miss Esmé Beringer, Miss Mabel Lewis Terry, Mr Cyril Maude, Mrs Tree, and many others no less celebrated, while the opera and concert hall were represented by Mr Joseph Hollman, Miss Marian Mackenzie, Miss Giulia Ravogli, Madame Alice Gomez, Miss Clara Butt, Vladimir de Pachmann, Johannes Wolff, and Madame Norcross. The highest praise

of the Indian Medical Service, three officers who retired from India last year with the Order of Knighthood, and Dr Patrick Manson, the medical adviser to the Colonial Office. Great improvements have been made in the conditions of life in some parts of the tropics during recent years. From the early days of the British occupation of India until almost the middle of this century the mortality among Europeans was very great. There used to be the most astonishing cases of mismanagement and obstinacy on the part of combatant officers who neglected and scorned the advice of their medical officers, while their men died like flies. The professor of medicine at Netley had many dread-ful stories about the barracks, hospitals, and commanding officers of the pre-sanitary period. We read of European regiments melting away like the visions of a dream. Cases are given where 120 or 130 new recruits were required for a battalion of 1000 men every year to keep up its strength. Report after report was sent in by medical officers, but no attention was paid to the matter until the Royal Sanitary Commission sent in its report in 1863 stating that on an average 69 per 1000 Europeans died annually, after which the Government at last took up the matter and the death rate of the troops in India is now not much greater than is that of those in this country. In fact India has improved so much as a residence that it does not much differ from Italy and some other parts in the south of Europe. In some portions of our tropical possessions things seem not to differ greatly from what they were in India in the early part of this century. In certain districts of West Africa the mortality is still very great and Mr Chamberlain, the Colonial Secretary, has arranged that only those medical men who have been specially trained in tropical medicine shall obtain appointments in the Colonial Services. In addition to the various colonial appointments there were many openings for medical men where a knowledge of tropical diseases would be useful and it is highly probable that a certificate showing the knowledge of the applicant in such subjects would be required when such appointments were made. There are surgeoncies to the railways in India which employ great numbers of persons and are provided with workshops and hospitals. European medical men are appointed at all the most important points. The emoluments are good and private practice is allowed. In the great tea districts on the hills towards the east of India many medical men are required for the care of the European and native employes. There was another occupation which many young medical men found extremely pleasant for a time—that of ship surgeon. The vessels of the many shipping companies which carry passengers to and from India, China, and Australia might have on board a large number of convalescents from tropical fevers, liver and bowel diseases, some of them sent to sea as a last chance, the patient being certain to die if kept on land. Officers proceeding on sick leave from India to Europe were often seriously ill and large numbers of such cases were sent in charge of young and inexperienced medical men in these passenger ships. Very often these medical men were alone and must have had some anxiety, as their knowledge of tropical diseases was only that obtainable at the ordinary medical school. The practitioner who settles at the Cape, or in China, or in eastern Africa and has to treat a case of tropical abscess, or malignant malarial fever, or beri beri at short notice is apt to find himself at first in some uncertainty.

Tropical practice is in many respects extremely interesting. There is scarcely a tropical disease regarding which insight is not wanted as regards its pathology. The recent plague epidemic has presented many opportunities for research and quite recently most valuable discoveries have been made by Major Ross, F.R.S., regarding the relation of the mosquito with the parasite of malarial fever. Only a year or so ago has the bacterium of yellow fever been discovered and at this moment experiments are being made to try to find a serum which will reduce the mortality of this deadly disease. Beri beri, sunstroke, negro lethargy, hæmoglobinuria, Indian non malarial fevers, and numerous others are awaiting the expert with the microscope, for undoubtedly microphytes and microzoa have much to do with tropical diseases.

Commenting on the small number of those who make a study of tropical pathology Dr Macconachie reminded his hearers that those of them whose tastes lay in this direction had great opportunities for making a name and at the same time keeping up the reputation of the Aberdeen school. The

entrance examinations for the Indian Medical Service are not difficult for a fairly well read man and a young surgeon with a good microscope and a knowledge of how to set about work will find his life extremely interesting. In the medical services for India and the colonies as well as in the Royal Army Medical Corps, a very large amount of the work is purely hospital work. In addition to this there are in India four large medical colleges with a complete staff of professors who in many cases are not allowed to practise. A specialist or investigator holding such appointments has therefore, an opportunity to follow his special bent as in this country. In India a successful civil surgeon soon makes a reputation and patients flock to his hospital from all parts. Some men have removed thousands of cataracts during their service and similarly with regard to urinary calculi. In the tropics every surgeon is a physician and every physician is a surgeon, in fact, every man who has a general hospital appointment must be prepared to undertake any medical, surgical, or obstetric case which comes before him. In conclusion, Dr Macconachie remarked on the advantages which the Government Medical Services offered to the young practitioner who could not afford to pay a large sum for an introduction to practice, and he made special mention of the greatly improved conditions of the Royal Army Medical Corps, strongly recommending that branch of the Service to those of his hearers whose inclinations lay in that direction.

It has been arranged to give a course of 25 lectures on Tropical Medicine with demonstrations by the Professor of Pathology on the various diseased conditions, bacteria, and entozoa applicable to the course. Over 30 students have entered their names to attend the class.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN extraordinary meeting of the Comité was held on May 11th, Dr CHURCH, President, being in the chair.

The PRESIDENT announced that he had appointed Professor Bradbury Croonian Lecturer and that his subject would be "Some Points Connected with Sleep, Sleeplessness, and Narcotics."

The following gentlemen who had been elected Fellows of the College at the previous meeting were duly admitted—Dr William Vicary Snow, Dr Henry Handford, Dr Herbert Ritchie Spencer, Dr Wilfred James Hadley, Dr Cyril Ogle, Dr William Halse Rivers, Dr William John Ritchie Simpson, Dr Percival Horton Smith, Dr Sydney Arthur Monckton Copeman, and Dr Arthur Ransome.

On the nomination of the PRESIDENT Dr Radcliffe Crocker was appointed as the representative of the College to attend an International Conference on the Prevention of Venereal Diseases to be held at Brussels, Sept 4th to Sept 8th. A report was received from the Laboratories Committee on April 14th informing the College that they had appointed Dr Cartwright Wood superintendent of the bacteriological department, and that his duties will include the preparation of diphtheria antitoxin and the testing of antitoxic sera sent to the Laboratories.—Dr PAYNE, in moving the adoption of the report, explained the great development of this department and the value which it had been to the community.—The SENIOR CENSOR (Dr CHEDDEN) seconded the motion and it was carried.

The following communications were received—
1 From Miss Roberts, offering for the acceptance of the College a portrait of her uncle, the late Sir William Roberts, by G. F. Watts, R.A.—The PRESIDENT, in the name of the College, accepted the gift and on the motion of the TREASURER (Sir DYCE DUCKWORTH), seconded by the SENIOR CENSOR, it was resolved to send a letter to Miss Roberts thanking her for her handsome gift. The date of the portrait was about 1870.

2 From the executors of the late Dr Hare announcing a bequest by him of £500, free of legacy duty, for the College Endowment Fund.—The PRESIDENT commented on the munificence of the gift and the TREASURER, seconded by the SENIOR CENSOR, proposed that a vote of thanks should be sent to Mrs Hare.—This was adopted.

3 From the Lord President of the Privy Council with

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH

Bromsgrove Urban District.—Dr Cameron laid, while making the council of this district against during coming from the statistics of one year, shows them by reference to the figures of the last decade that the work which they have, under his guidance, carried out has had a decided effect in a reduction of a death rate of 20·2 in the first 10 years of the decade to 16·2 in the second and unquenchable. In discussing the rates of isolation accommodation, Kidd points out how that the removal of a first case of infectious disease from a dwelling prevents that saturation of the rooms with infection which is not unlikely to occur in the protracted presence of a patient, more especially in such diseases as scarlet fever where the patient is able to move about freely. Dr Kidd refers with much satisfaction to the opening of the joint isolation hospital for the districts of Bromsgrove, Droitwich, and Redditch, but we are sorry to see that there has existed a certain amount of prejudice against this institution, so much so indeed that Dr Kidd has determined, so far as an attack upon the administration of the hospital involves him personally, to vindicate himself in a special manner. The management of a fever hospital is always a difficult task, the duty being rendered doubly onerous when attempts are made to damage the position of a medical man of such high professional attainments as Dr Cameron. We are glad to hear that his action will have a good effect upon those who think that a medical man may be spoken of very highly by Dr Kidd. He remarks that the isolation afforded a "practically certain immunity from the accidental introduction of diseases of any kind, it is also greatly diminished the severity of the local effects of vaccination itself." Indeed, it is surprising to anyone accustomed to the old fashioned vaccination to see the mildness of the symptoms produced by the use of this lymph—an almost complete absence of surrounding inflammation is now a rule rather than the exception.

Whitchapel Sanitary District.—The Jewish Board of Health have in this district recently given further evidence of their desire where possible to further sanitary reform and they have after inquiry directed that when a patient receives relief from the board of guardians the inspector appointed by this body shall distinct all rooms which patients with phthisis have inhabited. The officers of a sanitary authority are able, Mr. Joseph Isaac reports, to do very smoothly with the Jewish Inspector.

Sturton Urban District.—Dr Owen Coleman has clearly in the sympathy with those who yield to the pressure of patients by vaccinating by means of one insertion alone. In the course of some observations on this subject Dr Coleman remarks: "If he [the medical man] does not let him do it as he knows it should be done, or let him say he does not believe in it and decline to have a hand in it. But to vaccinate in one spot and to inject a certain child as thereby successfully (and in application efficiently) vaccinated, may be an easy matter since the parent is presumably if he consent to vaccination in the eyes of the ignorant and unthinking as a protective against small pox. Such a child is not efficiently protected but goes out into the world as if were, and later on possibly contracts the disease and operates in the returns amongst numbers of similar cases as having contracted small pox through successfully vaccinated." We have quoted Dr Coleman's comments in full because they are so much to the point at the present time when an attempt is doubtless being made to bring future sanitary and public health in a position of false certainty. The anti-vaccinationist will welcome the prevalence of infectious vaccination because it is certainly calculated further his ends. There is, indeed, very much force in Dr Coleman's position when he advocates one of two courses

—i.e., either vaccination properly performed or a certificate of conscientious objection No half measures. Let us have the vaccinated properly vaccinated and the unvaccinated registered as such.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In 33 of the largest English towns 6637 births and 3876 deaths were registered during the week ending May 13th. The annual rate of mortality in these towns, which had declined in the six preceding weeks from 23·1 to 16·5 per 1000, rose again last week to 17·7. In London the rate was 16·4 per 1000, while it averaged 18·6 in the 32 provincial towns. The lowest rates in these towns were 11·1 in West Ham, 12·2 in Gateshead, 12·9 in Norwich, and 13·1 in Swansea, the highest rates were 22·9 in Wolverhampton, 24·9 in Manchester, 25·6 in Liverpool, and 26·8 in Bedford. The 3876 deaths included 365 which were referred to the principal zymotic diseases, against 383 and 339 in the two preceding weeks, of these, 106 resulted from measles, 98 from whooping cough, 62 from diphtheria, 30 from scarlet fever, and one from small pox. The lowest death rates from these diseases were recorded in Crofton, Brighton, and Bristol, and the highest rates in Leicester, Manchester, Bedford, and Burnley. The greatest mortality from measles occurred in Manchester and Bedford, from scarlet fever in Bradford, and from whooping cough in Plymouth, Cardiff, Birkenhead, Burnley, and Hull. The mortality from "fever," showed no marked excess in any of the large towns. The 82 deaths from diphtheria included 40 in London, eight in Leicester, five in Liverpool, four in West Ham, four in Leeds, three in Bedford, three in Burnley, and three in Sheffield. One fatal case of small pox was registered in Hull, but not one in any other of the 33 large towns, and no small-pox patients were under treatment last week in any of the Metropolitan Asylums Hospitals and in the London Fever Hospital at the end of last week. The deaths referred to diseases of the respiratory organs in London, which had been 294 and 251 in the two preceding weeks, rose again last week to 257, but were 53 below the average. The causes of 53, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Bolton, Newcastle-upon-Tyne, and in 12 other smaller towns. The largest proportions of uncertified deaths were registered in West Ham, Portsmouth, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.—The annual rate of mortality in the eight Scotch towns, which had been 21·1 and 18·5 per 1000 in the two preceding weeks was again 18·5 during the week ending May 13th and exceeded by 0·8 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 11·8 in Perth and 13·7 in Greenock to 19·1 in Glasgow and 22·2 in Dundee. The 565 deaths in these towns included 27 which were referred to measles, 10 to "fever," and three to scarlet fever. In all 53 deaths resulted from these principal zymotic diseases against 76 and 62 in the two preceding weeks. These 53 deaths to an annual rate of 1·8 per 1000 which slightly exceeded the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 30 and 16 in the two preceding weeks, rose again to 27 last week, of which 20 occurred in Glasgow and four in Aberdeen. The 10 deaths referred to whooping cough showed a further decline from the numbers recorded in recent weeks, and included three in Edinburgh, two in Glasgow, and two in Dundee. The fatal cases of diphtheria, which had been three and five in the two preceding weeks, further rose to six last week, of which three occurred in Glasgow. The three deaths from scarlet fever corresponded with the number recorded in the preceding week, and included two in Edinburgh. Of the three deaths referred to different forms of

matter was one for the municipality Mr McCandlish, speaking for Leeds, said that any scheme brought forward should receive his colleagues' hearty coöperation. Mr F H Benthams of Bradford brought forward a motion expressing the opinion that phthisical inmates of workhouses should be treated elsewhere than in workhouses or infirmaries, and asking boards of guardians to consider the question with a view to providing isolated hospitals. The motion was carried.

SHEFFIELD

On May 10th there was held a large and important meeting in the banqueting room of the Outlers' Hall with a view to establish a branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. The Lord Mayor was in the chair and was supported by Sir William Broadbent, the chairman of the Organising Committee of the Association, and Professor Clifford Allbutt. The Chairman explained the objects of the meeting and the importance of the movement. Sir William Broadbent gave an account of the origin of the Association, its objects, the various criticisms to which it had been subjected, the nature of predisposition to tuberculosis, and the exceeding importance of prevention in medicine and the value of comparative pathology. Dr Dyson proposed the first motion affirming the formation of a branch and this being duly carried another was moved by Alderman W K Carter which dealt with the organisation of the branch. After this had been carried the usual votes of thanks were passed and a special tribute of thanks was paid by the Lord Mayor to Dr D Burgess, the local honorary secretary, to whose labours the success of the meeting was in great measure due.

PORTSEA

A discussion took place at the meeting of the Portsea Board of Guardians which was held on March 29th. The discussion arose out of the consideration of the report of the special Infirmary Committee appointed to examine into "the best means of treating our consumptives and other cases of tuberculous disease by the modern fresh air treatment." The report pointed out that the committee were quite convinced of the efficacy of the fresh air treatment as carried out at Ventnor and that although they could not expect the same success with ordinary infirmary patients as with the selected patients at Ventnor, yet they thought that great benefit would accrue by making certain structural alterations in the Portsea Infirmary. These were, shortly, making the windows larger and putting up a verandah. Mr H P Gaston, after speaking on the importance of fresh air and light, moved the adoption of the report. As for the erection of a sanatorium, that was a matter for the town council. The report was eventually adopted.

THE CASE OF HUNTER v CLARE

We have received the following appeal through Mr Rivers Wilson from the committee who are raising a fund in behalf of the widow of the late Mr H K Hunter—

The committee earnestly desire to draw the attention of members of the medical profession to the sad case of Mr Herbert Kingsley Hunter, who died suddenly on July 19th, 1898, at Gamlingay, at the early age of 30 years, leaving a widow totally unprovided for. The committee think that this case specially calls for the support of the profession, not only to relieve the sad condition of the widow, but also to serve as an expression of opinion on their part against the treatment Mr Hunter received and which there is only too good reason to believe led to his fatal attack.

The facts are briefly as follows—A few years ago Mr Hunter, after receiving his medical education in this country, went to Pennsylvania with his wife with the intention of settling and practising there. He entered as a student at Jefferson's College, Philadelphia, a recognised State University, and after passing through the ordinary curriculum graduated as M D. Shortly afterwards, owing to domestic reasons, he was compelled to return to England and to take steps to qualify himself to practise in this country. Accordingly he acquired the diploma of the London Society of Apothecaries and having become a registered medical practitioner bought a practice at Gamlingay, in the county

of Cambridgeshire. He soon became popular and had every chance of a prosperous career, but complaints were made against him before the General Medical Council. (1) that he called himself "Dr" on the strength of an American degree, (2) that he made use of the style "Physician and Surgeon," being only a Licentiate of the Society of Apothecaries. In consequence of representations from the General Medical Council Mr Hunter agreed to make no further use of his degree, and asked the Council what title he should use to indicate he was lawfully qualified to practise medicine and surgery. That body refused to advise and Mr Hunter thought the matter was at an end. Great was his consternation when one day he received a summons to attend before the petty sessions at Caxton in consequence of a prosecution instituted by the General Medical Council. So profound was the shock that he was taken ill the same day with cardiac symptoms, from which he had never before suffered. At the petty sessions he was convicted by the justices of "wilfully and falsely" styling himself a "physician," but at this stage the Society of Apothecaries intervened on his behalf, and appealed to the Divisional Court of Queen's Bench. It may be stated, however, that all the cost of the trial before the magistrates had to be defrayed by Mr Hunter himself, and the whole matter tended greatly to injure his practice, for it was reported throughout his neighbourhood that he was an American quack, the action of the General Medical Council could not but appear to corroborate popular rumour that he was an unqualified practitioner. Before the appeal came on in London Mr Hunter, returning home after a hard day's work, had a recurrence of the symptoms which had first manifested themselves on the receipt of the original summons and died quite suddenly. A report was immediately circulated that he had committed suicide, but Mrs Hunter acted promptly by sending at once to Cambridge for medical assistance and a post-mortem examination annihilated the cruel libel.

The result of the trial before Justices Lawrence and Channell is well known and until the decision there given is reversed, or fresh legislation has abrogated it, it would appear that medical men, lawfully qualified to act in every respect as surgeons and physicians, may be prosecuted and fined for calling themselves such. The decision is a far reaching one, for not only are all Licentiates of the Society of Apothecaries subject to this penalty, but medical and surgical graduates of our universities are equally involved. For if there is any meaning in the decision of the Divisional Court, it is that the titles "Physician and Surgeon" are at law rigidly restricted to Fellows, Members, and Licentiates of a College of Physicians or Surgeons respectively.

Under these circumstances it seems to the committee that important principles are at stake, affecting the well being of a large portion of the profession and that the Hunter Fund is deserving of every possible support, if for no other reason than as a practical protest against the present iniquitous state of the law as shown by the recent trial at the Royal Courts of Justice.

Committee

LONDON SCHOOL OF MEDICINE FOR WOMEN—

A dog show will be held on June 3rd at the London (Royal Free Hospital) School of Medicine for Women, 8, Hunter street, Brunswick square, W O. Only qualified practitioners, members of the teaching staffs at the medical schools, and medical students may exhibit. The committee has made arrangements to include as eligible dogs belonging to members of the families of the above. The show which has been licensed under the Kennel Club will last one day, closing at 7 P M. The judging will begin at 1.30 P M. 26 classes have been provided, three prizes are offered in each class and a large number of special prizes have been offered. Capt Barry, Mr E W Allen, and Mr G R Krehl have kindly volunteered their services as judges. The proceeds are to be devoted to the building fund of the school.

"fever," two were registered in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 117 and 109 in the two preceding weeks further fell to 97 last week, and were 12 below the number in the corresponding period of last year. The causes of 21, or nearly 4 per cent, of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had declined in the four preceding weeks from 33.4 to 24.8 per 1000, rose again to 26.7 during the week ending May 13th. During the past four weeks the rate of mortality in the city has averaged 27.8 per 1000, the rate during the same period being 16.8 in London and 17.6 in Edinburgh. The 179 deaths registered in Dublin during the week under notice showed an increase of 13 upon the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against 12 and seven in the two preceding weeks, of these three resulted from "fever," two from scarlet fever, two from whooping cough, and one from diphtheria, but not one either from small-pox, measles, or diarrhoea. These eight deaths were equal to an annual rate of 1.2 per 1000, the zymotic death rate during the same period being 1.7 both in London and in Edinburgh. The deaths referred to different forms of "fever," which had been three and two in the two preceding weeks, rose again to three last week. The two fatal cases of scarlet fever exceeded the number recorded in any week since the end of March last. The two deaths from whooping cough showed a further decline from the numbers returned in recent weeks, while the mortality from diphtheria corresponded with that recorded in the preceding week. The 179 deaths in Dublin last week included 28 of infants under one year of age and 63 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons considerably exceeded the number recorded in the preceding week. Seven inquest cases and six deaths from violence were registered, and 74, or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent, of the deaths in the city last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

The following appointments are announced—Surgeons D. J. O'Malley to the *Dido* and H. W. M. Rees to the *Coat of Wellington* for the *Tasman*.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R. W. Mapleton acts as Principal Medical Officer, North Eastern District, until further orders. Major A. P. O'Connor has embarked for South Africa, and Major T. P. Woodhouse has arrived in the Eastern District for duty. Captain E. M. Pilcher has joined at the Royal Arsenal for duty. Lieutenant J. M. Sloan has assumed Medical Charge of the field hospital and troops at Barry Camp.

INDIA AND THE INDIAN MEDICAL SERVICES

The services of Major R. J. Windle, R.A.M.C., are placed temporarily at the disposal of the Government of Bombay for employment on plague duty. Captain J. C. Lamont (Bengal), Professor of Anatomy, Lahore Medical College, is granted furlough out of India for eight months. Captain H. G. Melville (Bengal) is appointed to officiate as Professor of Anatomy, Lahore Medical College, until further orders. The services of the undermentioned officers are placed temporarily at the disposal of the Government of the North Western Provinces and Oudh for employment on plague duty. Captain Merewether, 7th Bengal Cavalry, Captain Grant, 2nd Battalion 4th Gurkhas, Captain Stanton, 3rd Bengal Infantry, Captain Maxwell, 18th Bengal Cavalry, Lieutenant Hill, 34th Pioneers, Lieutenant Wheeler, 28th Punjab Infantry, Lieutenant McK. T. Hogg, 9th Gurkha Rifles, Lieutenant Preston, 40th Pathans, Lieutenant Sproule, 1st Bengal Pioneers, and Lieutenant Barry, 2nd Bengal Infantry. The services of Lieutenant-Colonel A. Deane (Bengal) are replaced at the disposal of the Foreign Department. Lieutenant Colonel Scott Reid goes as Administrative Medical Officer to the Central Provinces, relieving Colonel Hutchison, who takes up his substantive

appointment at Allahabad as Inspector General of Civil Hospitals North-Western Provinces and Oudh. The Queen has approved of the retirement from the service of the undermentioned officers—Major Louis Tarleton Young, Bengal Establishment, and Lieutenant-Colonel William Henry Thornhill, Madras Establishment (post-dated to April 9th, 1899).

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Captain Charles H. Gough, Derbyshire Yeomanry Cavalry, to be Surgeon Major, Surgeon Lieutenant A. Phillips to be Surgeon Captain.

YEOMANRY CAVALRY

Wiltshire (Prince of Wales's Own Royal Regiment), Surgeon Lieutenant E. Kingscote to be Surgeon Captain.

VOLUNTEER CORPS

Rifle 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment) Surgeon Lieutenant Josiah Field Hall resigns his commission and is appointed Second Lieutenant 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers. Brigade Surgeon Lieutenant Colonel C. P. Skrimshire resigns his commission, also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement, vacating thereby his appointment as Senior Medical Officer to the South Wales Volunteer Infantry Brigade. 2nd Volunteer Battalion the Welsh Regiment William Frederick Brook to be Surgeon-Lieutenant 1st Tower Hamlets. Charles Ayton Marrett to be Surgeon-Lieutenant.

RECRUITS' TEETH

We lately reported in our Parliamentary Intelligence that 1767 recruits otherwise up to the standard physically were rejected last year on account of "loss or decay of many teeth." It seems a pity that the services of these young men who are ready and willing to become soldiers should be lost to the country in consequence of a perfectly remediable disability. The causes which conduce to bad teeth are not very well understood, but it seems tolerably certain that they may co-exist with what is commonly called a sound constitution. The fact of a youth being the subject of premature dental decay does not *per se* detract from his expectation of life. Provided he can masticate his food he should have as good a chance of reaching to old age as any of his contemporaries whose teeth remain intact. In cases where there is nothing else amiss with a recruit it would therefore, we should imagine, be worth while for the State to supply his deficiencies. The gain to the individual would be enormous, while the cost to the public purse would be but trifling. In addition to the initial outlay for false teeth and sets of teeth the Government would have to maintain dentists at all large stations at home and abroad, but as it is the need for skilled aid of this description is a crying one. Military surgeons cannot be expected to excel in mechanical dentistry.

The Queen has given to each of the undermentioned officers in Her Majesty's Army Her Royal licence and authority to wear the insignia of the Imperial Order of the Osmanieh or of the Medjidieh, as stated below, in recognition of their services in Egypt and the Soudan during the recent campaign—The Order of the Medjidieh of the Second Class Surgeon General William Taylor, Medical Staff. The Order of the Medjidieh of the Third Class Lieutenant-Colonel Arthur Thomas Sloggett, R.A.M.C. The Order of the Osmanieh of the Fourth Class Captain Philip Henry Whiston, R.A.M.C. The Order of the Medjidieh of the Fourth Class Captain James Wiles Jennings, R.A.M.C., and Captain Henry Nason Dunn, R.A.M.C.

The War Office has decided that the unvaccinated wife or children of a soldier cannot be allowed to live in barracks or be conveyed to any foreign station at the public expense.

THE LANCET April 29th 1899

VACCINATION PROSECUTION.—At Exeter on May 12th a man who refused to pay a fine was sentenced to one month's imprisonment for non-compliance with an order to have his child vaccinated. The chairman of the magistrates remarked that it was for the good of the children and for the good of the country that they should be vaccinated.

Correspondence.

And alienum patient.

"ASTHMA IN RELATION TO DISEASES OF THE UPPER AIR PASSAGES"

To the Editors of THE LANCET

SIR—The discussion on this subject at the Laryngological Society of London will have been useful if it has done nothing more than elicit the interesting letter in THE LANCET of May 13th from Mr Armstrong pointing out the connexion between goitre and asthma. I am fully convinced of this connexion and I had prepared notes on this point for the last speaker did not finish until past seven the hour for adjournment, so I was compelled to call upon the operators of the discussion, but as chairman I waited until the end of the discussion, but as chairman I waited until the end of the discussion.

words. If I had had the opportunity I would have insisted on the importance of recognising the threofold origin of asthma. The diseases of the individual, in many asthmatics goitrous symptoms are met with and many of the sufferers are neurotic. Some morbid condition of the mucous membrane of the respiratory tract. The direct exciting cause—i.e. the pollen of certain grasses, igeacanth, and certain odours, as of horses and cats. In bronchial asthma the condition of the digestive tract also requires careful consideration. From my experience in the treatment of hay fever and asthma I am convinced of the necessity of paying attention to all the factors concerned in the production of the asthmatic state. Indeed, I regard asthma as nothing more or less than a symptom, and before any treatment is undertaken the cause of it should be investigated. It is only by the judicious combination of general and local treatment that we must look to relieve our patients of one of the most distressing complaints to which flesh is heir.

"THE PATHOLOGY OF THE PERICARDIUM"

To the Editors of THE LANCET

SIR—Dr Harry Campbell in THE LANCET of April 29th, 1899 criticises my paper on "Certain Points in the Pathology of the Pericardium" published in THE LANCET of April 22nd and 1899. As the title implied, my paper was upon the pericardium and the respiratory vascular pump was only introduced to show the place of the pericardium in the general venous circulation. In the *Journal of Physiology*, 1897, will be found a paper by Leonard Hill and myself devoted to the vascular functions of respiration and in that paper account Dr Campbell will find several of his questions answered by actual experiment.

By Section 1 of his letter Dr Campbell would appear to imply that Leonard Hill and I claimed originally for the remarks which I made on the vascular functions of respiration. The fact that the respiratory movements assisted the circulation was not only taught by Cohnheim and before him but finds a place in elementary text-books of physiology. We that the respiratory and other movements of skeletal muscles play well nigh as essential a part as the heart in the circulation of the blood and that in the erect position the such contractions of skeletal muscles, and this is all that was claimed as original in my paper.

Dr Campbell is of opinion that under ordinary circumstances respiratory movements do not aid the circulation to an appreciable extent. Respiratory waves appear on nearly every trace of a blood pressure experiment even during quiet breathing, and when it is considered that during deep respiration in man the negative pressure of the thorax varies from -1 to 2 mm Hg in expiration to -30 mm Hg during inspiration it must be admitted that the thorax must exert a very considerable pumping action on the blood. The blood tends to be sucked into the lungs during inspiration, whilst the rise of pressure during expiration passes it on to the left heart as the way to the veins is barred by the pulmonary semilunar valves. A constant negative pressure, as Dr Campbell states, is maintained in the pulmonary vessels when the capacity of the thorax is increased for a considerable time than it can in the alveoli. The air tends to flow into the alveoli and the blood into the pulmonary vessels until equilibrium is once more established and then further flow arising from the increased size of the thorax ceases. Where, however, the intra-thoracic pressure oscillates the blood is sucked in when the pressure is low and pushed on as the pressure rises, for the valves prevent regurgitation. In short, in a system provided with valves a periodic change of pressure at any part will produce a flow along the system in the direction of the valves.

In Section 3 of his letter Dr Campbell states that I contended that the expiratory act favours the pulmonary circulation. It is not explanation by itself which favours pulmonary circulation but expiration after inspiration has sucked blood into the lungs. Hill and I have carried out the circulation of an animal (after the heart had stopped) by rhythmic and alternate compression of the abdomen and thorax.

Dr Campbell states that "in such athletic exercises as running the mean size of the chest is increased—as inspirations being full and expirations shallow—and as breathlessness increases the latter becomes shorter than the former." Dr Campbell here describes the condition which follows excessive and unworked exercise in an untrained person whose heart and respiratory vascular pump fall. I can positively state that in a well trained cross country runner whose heart and respiratory pump are efficient for the exercise he undertakes inspirations are profound and expirations complete. The air exchange at maximum wave of blood is inspired from the abdominal veins to meet the air in the lungs and is expired into the left ventricle and aorta. In such a manner it will be found that the abdominal wall contracts and hardens with each inspiration (Section 5 of Dr Campbell's letter). This reversal during exercise of the usual inspiratory condition of the abdominal wall is an observation, not a deduction. It may also be observed when a fall of blood pressure is produced in an animal in the erect position and in cases of pericarditis with effusion.

(Section 4 of Dr Campbell's letter) Mythical descent of the diaphragm would push the liver in front of it without compressing it. It was not more or less resisted by the remaining of the "muscular sphere" containing the great veins of the abdomen. As it is the muscular sphere enclosing and compresses. The portal vein and its radicles emptying the blood through the liver into the hepatic veins in the diaphragm for the inferior vena cava. The blood cannot return to the mesenteric arteries against arterial pressure. I have shown that the pressure exerted is ample sufficient to empty the portal vein through the liver at each contraction of the muscular sphere. The blood which reaches the capillaries inferior vena cava from the legs is simultaneously pressed up into the right heart whence it cannot return when once past the tricuspid valve. Hence to the legs is prevented by the valves in the femoral veins. I trust that these remarks may satisfactorily clear up the obscure passages in my paper.

I am, Sirs, yours faithfully

Harold L. BARNARD

"A CONTRIBUTION TO THE ANATOMY OF THE PERITONEUM"

To the Editors of THE LANCET

SIR—I have read with considerable interest the article under the above title in THE LANCET of May 13th.

Case 1, I presume, that described by Mr Mansel Poulton in a clinical lecture reported in THE LANCET of April 1st as a hernia into the "post-cæcal" pouch. As Mr

fores the sacculi (the fossa of Blandin) This form of hernia is exceedingly rare. So far as I am aware only two previous cases are recorded. The first is described in a most meagre and unsatisfactory manner by Engel

who pronounced it to be one of 'retro-cæcal' hernia. Leichtenstern, with whom I agree, looks upon it as a hernia into the fossa of Biesadecki. The second case was shown at the Pathological Society in 1889 by Dr Mott. The specimen was examined and the diagnosis was verified by Mr Treves.

With regard to Case 2 I am inclined to agree with Mr Keith that this is an example of right duodenal hernia occurring into the fossa to which I have given the name "fossa of Waldeyer." The mention of two most important points is omitted from Dr Smith's description. One refers to the position of the superior mesenteric artery and the other to the condition of the upper end of the jejunum. As I have shown elsewhere,¹ the fossa of Waldeyer, into which a right duodenal hernia occurs, is invariably bounded in front by the superior mesenteric artery. In the neck of the sac of this form of hernia, therefore, the artery (or its continuation the ileo-colic in the case of large sacs) always lies. When the sac in its enlargement reaches the ascending colon one of two things may happen. The colon may be pushed to the right and backward, as in a case recorded by Gerard Marchant, or the sac may pass behind and appear on the outer side of the colon and there enlarging further may push the colon downwards and inwards to the middle line, as in Brösike's case and in Case 2. (In my work on Retro-peritoneal Hernia illustrations 18 and 19 show these dispositions of the colon.) The second point omitted in Dr Smith's description has reference to the condition of the upper few inches of the jejunum. In one-half of the recorded cases of right duodenal hernia there was an adhesion of the jejunum to the anterior surface of the lumbar vertebra. Such adhesion was present in two of Brösike's cases and he over hastily concluded that it was essential to the production of a "parajejunal fossa," which formed the sac of the hernia. This "parajejunal fossa," however, I have shown to be nothing else than the fossa of Waldeyer under slightly altered circumstances. The fact of the existence of this adhesion in half of the recorded cases makes it necessary to describe two forms of right duodenal hernia—a "hernia mesenterico-parietalis para duodenalis" and a "hernia mesenterico-parietalis para jejunalis."

Specimen 1084 in the Guy's Hospital Museum is a very beautiful example of a right duodenal hernia. It is from a case of Dr Moxon's and was described in the Guy's Hospital Reports, vol. xvi, 1871, p. 131, by Dr Pye-Smith. A specimen in the St Mary's Hospital Museum was described in the Transactions of the Pathological Society of London, vol. ix, 1893, page 67, by Mr Jackson Clarke. It was removed from a patient under the care of Mr Page. So far as I have been able to ascertain, these two and a specimen shown by me in my "Arris and Gale" lectures are the only ones in existence in England.

If Mr Keith will be good enough to report upon the two points which I have mentioned I am sure that the work of future commentators will be much facilitated.

I am, Sirs, yours faithfully,

Leeds, May 13th, 1899. B G A MOYNIHAN

MALIGNANT PIGMENTED TUMOURS

To the Editors of THE LANCET

SIRS,—Dr Rolleston in his most interesting lecture on "Secondary Melanotic Sarcoma of the Liver" published in THE LANCET of May 13th touches on many points of the greatest pathological interest. One cannot, however, help being struck by the fact that though he has carefully summarised the present state of our knowledge of the subject of primary pigmented tumours the most important links of the chain are yet wanting and really very little is definitely known of their true nature. The explanation of this is, I suppose, that until quite recently all pigmented tumours running a malignant course were believed to be sarcomatous and mesoblastic in origin. Recent observation has done much to disprove this. The two most usual situations for melanotic tumours to occur in are the skin and the eyeball. We now know that of those originating in the skin, some are sarcomata, others are carcinomata, while yet others appear to be intermediate between the two, possibly consisting of cells which in development have never become differentiated and cannot be said to belong definitely to epiblast or hypoblast.

¹ Retro-peritoneal Hernia (Baillière, Tindall, and Cox).

In melanotic carcinoma the cells lining the walls of the alveoli are often so distinctly columnar in form and arranged side by side, that their epithelial character cannot be doubted. Clinically the distinction between the two is very marked. In sarcoma the primary growth is not as a rule very large, it is frequently distinctly encapsuled and is not prone to early ulceration. The rapid infection of the lymphatic glands and dissemination of the secondary growths throughout the body while the primary growth is yet small is notorious. The prognosis is very bad, so bad that, according to Erichsen, if the primary growth has attained the size of a filbert no local treatment can cure the patient although by relieving him of one source of infection it may retard death. In melanotic epithelioma the longer duration and slower progress of the growth, the early ulceration, the diffused brown pigmentation of the skin, and the late appearance of glandular and visceral infection by secondary growths, are leading characteristics.

Dr Rolleston, dealing with this point, says "It is not, as far as can be seen at present, a matter of any great clinical importance what the exact structure of a malignant melanoma is, though more careful classification in the future might be expected to show that there was some difference in the rapidity of generalisation." I would venture to differ from this and to suggest that the character of the growth would very materially affect the gravity of the prognosis. The reported cases of melanotic epithelioma show that the tendency to glandular and visceral infection is very much less and that early and complete removal ought to give a fair chance of recovery without subsequent recurrence.

There is one point of some interest to which I would refer. Mixed with the tumours and nodules in melanotic sarcoma there are sometimes black spots or patches which look as though they were mere deposits of pigment without any new growth, such are seen in the mucous membrane of the stomach, renal pelvis, and bladder. Lücke says that a careful examination always reveals the presence of cells in spots thus affected, but Thiersch relates a case of melanotic carcinoma of the skin in which at certain points nothing could be discovered but a diffused brown staining of papillæ; the texture of which was perfectly normal. I suppose that in Dr Wickham Legg's case the dark appearance of the face suggesting argyria was due simply to this staining of the papillæ. It is common knowledge that the distribution of pigment in these growths is very capricious. The melanin particles are lodged in and among not only the characteristic cells of the tumour, but in and among those of its fibrous matrix and even in the walls of its vessels. It would be most interesting to know whether there is any clinical distinction with regard to intra ocular melanomata. The majority of these growths are undoubtedly sarcomata arising from the uveal tract, but a few have been shown to be carcinomata taking origin from the epithelium of the ciliary glands. The other regions of the body where primary pigmented malignant growths have been described as occurring are the gums, rectum, liver, lymphatic glands and, according to Virchow, the adrenals and vesicular seminæles. I have little doubt that as our knowledge of these tumours progresses and every pigmented new growth is subjected to a searching and critical examination melanotic carcinomata will be found to be of more frequent occurrence among melanomata than is at present supposed.

I am, Sirs, yours faithfully,

Leicester May 14th, 1899

GEORGE A. CLARESON

"MATE OR PARAGUAY TEA"

To the Editors of THE LANCET

SIRS,—I have read with much interest Dr Gordon Sharp's article on *Maté* in THE LANCET of April 1st. Having lived for some years amongst the gauchos of Argentina—the *maté* drinkers *par excellence*—and having in my time consumed much *maté* myself I venture to dispute some of the conclusions and somewhat hasty generalisations, as they appear to me, arrived at by him after an experience with the herb of but one week only during which time, moreover, he drank it prepared in a quite unusual manner and in conjunction with other ingredients not in themselves always easy of digestion, and added to the *maté* in proportions which are not stated. According to Dr Sharp *maté* is not only a nauseous but a positively deleterious beverage. He records that the taste of it everlastingly remained, the appetite was lost, there was a strong inclination to vomit, a sense of drowsiness and languor was

experienced with impaired capacity, for physical exertion, and, worst feature of all, a distaste for tobacco accompanied the distressing symptoms.

Such is the gruesome tale of Dr Sharp's brief experience with the herb. In trying to discover the cause of these untoward results several considerations present themselves. Was the mate employed itself sound, unadulterated, and fresh? Is it possible that Dr Sharp by some coincidence was the subject of a rhinoid attack at the time of his experimentation? Lastly, might not the cream and the sugar which were added to the mate have been at fault or in excess? And, however this might be, is it wise to take any "union", "hot" with cream and sugar, immediately before or immediately after dinner? I, in no way enthusiastic for mate, but I have the Englishman's love of fat play and I do feel that at Dr Sharp's hands the herb has not had fair play. It has never had a chance. Taken as it was by him it would have upset the stomach of the stoutest man of the Pampas. In fact, from what I know of the matter nothing would have induced any one of them to try it so unless as an emetic. The garcho invariably takes his mate without the

"A CRITICISM OF THE MORE COMMONLY EMPLOYED TESTS FOR ALBUMIN IN URINE"

I am Sirs, yours faithfully
J H DAVBER, M B Oxon
Charlton-street, W., 1839

British workman do as much on his beer ?
Shut is most refreshing when taken after physical fatigue
It should not be taken with food
The meat diet with water
Meat made and served in cups and saucers as tea and coffee
are generally in this country and taken at meal-times as
mistake Taken so it is decidedly inferior to either and can
never compete with them successfully
In the towns of
South America it does not replace tea and coffee and is but
little used Personally I do not think that it will ever
become very popular in this country The taste for it has
to be acquired, it has so essentially a flavor of its own All
my attempts to popularise it in my own household have met
with the most signal failure, where, to be perfectly frank,
it is generally allied to as "that horrid mate," and I am
considered to take it only from sentimental motives
The truth of the matter appears to me to be that we have
little need for it here in England On the vast prairies of
South America staying power in man and horse is a great
desideratum, the distance to be traversed often great,
and food for man can be procured often only at long
intervals Hence mate which can be easily made wherever
there is water and which has certainly great sustaining
power, is an invaluable commodity Even to a "gringo" or
"foreigner the relief for it there comes soon, for it is often
"Hobson's choice" and it may easily fall out that mate and
cigarettes are the only two courses on the bill of fare
In crowded England and where different conditions obtain and
the stomach is rarely empty for more than 30 minutes at a
time mate seems to me nearly as out of place as the jasso or
the bolao The perfume, the dyspeptic, *et hoc genus omne*, will
quite at one with Dr Sharp It is no beverage for
such The British workman is too wedded to his beer
and his groove is too narrow and set for him to
easily are national habits eradicated and replaced by
others But there are times even in this country and after
love when to a mate-drinker, were it obtainable, mate would
be welcome—after exercise in the open air, weary day with
pulling against the stream, or with cycling over indifferent
roads, but to the novice even then I think it would appeal
in a cup of tea or a whisky and better world always be more
formidable

"A CRITICISM OF THE MORE COMMONLY
 EMPLOYED TESTS FOR ALBUMIN
 IN URINE"
 To the Editors of THE LANCET
 Sirs,—With regard to Dr. Colquhoun's letter in
 THE LANCET of May 13th, 1899 may I be allowed to
 state that my reasons for not inserting the details of the
 processes by which my results were attained for the general reader
 first, that my article was intended for the general reader
 secondly, that my conclusions were only the incidental pro-
 duct of an investigation into the subject of albuminuria, the
 details of which I hope to be able to publish later?
 In the interval since the appearance of Dr. Colquhoun's
 article on Carbolic Acid as a Test for Albumin in THE LANCET
 of May 6th, 1899, I have made use of the test, by the side of
 the reagents which I usually employ, in some 20 specimens
 while acknowledging that in Dr. Colquhoun's hands it may
 give the satisfactory results which he claims for it it does
 not seem to me to have any advantages over easily and economi-
 cally, Millard's reagent, and several other well known tests.

Owing to the large amount of carbolic acid held in solution by the absolute alcohol and the ease with which the alcohol evaporates crystals of carbolic readily separate out and render the fluid not only difficult of transport but also awkward to work with. It is certainly a delicate test for albumin, but not so delicate as salicyl sulphonic acid, Millard's reagent or Tanret's solution. Great delicacy is not, however, an advantage in clinical work and, as I have pointed out, is a serious objection to salicyl sulphonic acid as a routine test. The precipitate produced by carbolic acid and alcohol in albuminous urine is not easily seen, especially where it is faint, owing to the tendency of the urine and the reagent to mix. Further, the milkiness produced by the emulsification of the phenol by the water of the urine is a serious drawback. Nucleo-proteids give a well marked reaction and this, unless Dr Colquhoun has excluded it, may perhaps account for the albumin in small quantities which he has found in such a large proportion of his patients. Although filtration will remove the obvious "mucous" cloud it does not remove the nucleo proteids.

While allowing that Dr Colquhoun's method of estimating the relative delicacy of his test has the claim of simplicity I think that in using egg albumen and from it drawing inferences as to the reaction of the albumin found in urine he is making an assumption for which at present there is no justification. In fact, as Dr Colquhoun himself mentions, *in coagulating temperature and its reaction with other egg albumen* differs from the albumin of serum, and in view of these facts we cannot assume that their reactions with other reagents are the same. It therefore seems to me that in spite of the greater difficulty and complexity of the method with care a more truly accurate estimation can be made by examining albuminous urines and then separating out and weighing the albumin. Urine is such a highly complex and variable fluid that inferences drawn by comparison from artificial solutions are, I think, to be avoided as far as possible until we know much more than at present of the nature and properties of its constituents.

I am, Sirs, yours faithfully,

P J CAMMIDGE

St. Bartholomew's Hospital E.C., May 15th 1899.

To the Editors of THE LANCET

SIRS,—I beg to make a correction in my paper and also to add an amendment. The word "saturated" escaped my scrutiny. As a matter of fact the solution which I have used for the last six months consisted of about five parts of saturated solution of carbolic acid in absolute alcohol to three parts of absolute alcohol. The test as I described it is a slow one and perhaps confusing to those who have not experimented on solutions of albumin. An immediate result is obtained by warming the fluid to be tested to about 70° C and then pouring the carbolic solution to the amount of about one cubic centimetre on the surface from a pipette so that it penetrates the albuminous fluid to some depth before rising. The warming may be continued so as to avoid all milkiness from separation of carbolic acid. A pearly milkiness due to albumin at once appears and is quite diagnostic. The test is quite as delicate as I described it and is worth mastering.

I am, Sirs, yours faithfully,

May 15th 1899. WALTER COLQUHOUN

"THE CENTENARY OF THE CHARTER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND"

To the Editors of THE LANCET

SIRS,—It is sincerely to be hoped that your appeal to the Council of the College to make some recognition of the Members a part of the centenary celebration will meet with a response. As you say, nothing could be more fitting than such a step at the present time and it cannot be "beyond the wit of man" to devise a plan by means of which the Members may be accorded a share of representation without interfering with the just rights of the Fellows. The scheme of the Members put forward two or three years ago was rejected by the Fellows and Council, let the latter now try their hand and their proposals will be received with respect by all. There is nothing whatever irreconcilable in the attitude of those Members who have taken up this question. They consider that their claim is a just one in view of the

constitution of the College, but they are quite willing to accept any reasonable proposals and to leave the settlement of details to the Council.

I am, Sirs, yours faithfully,

May 16th 1899.

W G DICKINSON,

THE FEES OF MEDICAL WITNESSES

To the Editors of THE LANCET

SIRS,—It is satisfactory to find from the leading article in THE LANCET of May 6th that attention is at last being called to the inadequate fees paid to medical witnesses in criminal courts. The members of no other learned profession would consent to leave their work and possibly travel many miles for the sum of a guinea a day, second class return railway fare, and 2s 6d a night. I have occasionally to go to an assize town 50 miles away and have been detained there for a week or more. The fees earned have not paid my expenses. My patients have been left in charge of a locum tenant to whom I have to pay three guineas a week. Irrespectively of operation cases, the total loss on the week's work has been about six guineas. Since this arrangement affects so slight a proportion of the people of this country it is doubtless deemed a small thing by the Government, but it is a very real hardship and heavy burden on a class of men whose services in the detection of crime are of value to the State. It is deeply to be deplored that the Home Secretary does not see his way to help us, more particularly as the amount of increase in the fees would be so small a sum in the aggregate. Surely two guineas a day is the very least that ought to be offered for the exclusive service of an expert who often makes more than twice that amount at home. I sincerely trust that you will kindly continue to help us in the matter.

I am, Sirs, yours faithfully

May 17th, 1899

PSEUDONYM

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Never ending Sewage Difficulty

THE adjourned Local Government Board inquiry into the bacterial sewage purification scheme of the Manchester Corporation was closed on May 1st, and the next day the Commissioners, Major General Orozer and Dr Theodor Thomson paid a visit of inspection to the works at Davyhulme and the corporation land at Carrington and Flixton. The application of the corporation was for sanction to borrow £160,000 to cover the estimated cost of the scheme. This inquiry occupied two days in January, when the evidence of experts with regard to the bacterial scheme was given, and it was then adjourned to enable details to be prepared and further experiments made at the Davyhulme works. Though the scheme is of immense consequence to Manchester, the interest it excites is not merely local, but widespread, and it is said that authorities throughout the country are watching its progress in the hope of benefiting by her costly experience. Dr Percy Frankland and Mr W H Perkin, jun., Professor of Organic Chemistry at Owens College, both said that the experiments continued to be highly satisfactory and that there could be no question that the scheme was capable of producing a satisfactory effluent. Mr Gilbert J Fowler, the resident chemist at the works, gave elaborate detailed evidence as to the weekly results of the experiments with the bacteria beds. He said that the effluent at its worst improved the quality of the water of the Ship Canal. At present, however, that might easily happen. Dr Thomson said that Mr Fowler was to be congratulated on the amount of labour involved in the preparation of his evidence—"the work contained in the documents and tables upon which it was based was really monumental." The report will be anxiously awaited. The summons against the corporation for penalties for fouling the Irwell and Mersey was again adjourned by Mr Yates at the Strangeways County Court from May 4th to 30th. At the last meeting of the City Council Sir Bosdin Leech, chairman of the Rivers Committee, spoke of the difficulties arising from the pouring into the drains of noxious fluids from various manufactories "at irregular intervals in large quantities sometimes acid, sometimes alkaline and often charged with chemical or other matter that came down without warning and necessitated an immediate change of

"Some of the manufacturers in the out-town treatment." Under the jurisdiction of the Manx and Lancelotti Com- But now that the city drainage-scheme has been extended into the out-townships these ingenious occupiers of those works "had applied to turn the effluents into the city sewers for convenience and in order to avoid the jurisdiction of the Joint Committee." Regulations have been made to meet this difficulty, but these trade effluents will need constant watching. Between the Local Government Board on the one hand, the Manx and Lancelotti Joint Committee on the other, and the difficulties somewhat improperly caused by the producers of various trade effluents, the Rivers Com- mittee, or the corporation, recall to mind that patient animal which though strong was crouching between two burdens, only in this case the burdens are more than two, and Sir Bosdon Leech somewhat pathetically told the Council that the Rivers Committee were not on a bed of roses—"a bacteria bed"—some heartless councillor interjected. They had to serve he said, not two but four masters first their own citizens who had rejected the current scheme, then they had the Local Government Board holding the purse strings and insisting on the Council still clinging to the culvert scheme and harassing the Rivers Committee on every possible occasion, and, lastly, "the Joint Rivers Board, who, seeing the committee bound hand and foot, insisted on hogging the willing horses who would go if he could. Looming in the distance was the Royal Commission, whose decision might revolutionise everything and introduce new principles for dealing with sewage. Like Job, too, the Committee were troubled with boils of kind friends who thought they could easily settle the sewage question." Probably the tangle in Manchester is greater than in most places but till this transaction period is passed similar difficulties will often be encountered.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Town Council
At a meeting of the Edinburgh Town Council held on May 9th it was decided that Bailie Pollard should be sent as a representative of the Council to the Congress to be held in Berlin in May on the subject of "Infectious Diseases." A letter was read from Bailie Pollard (who was absent) intimating that he intended to go at his own expense. The Lord Provost expressed the indebtedness of the town Council to Bailie Pollard for the great amount of time and trouble which he had taken in connection with public health matters and more especially with the question of infectious diseases.

The Sanitary Condition of Edinburgh
The Edinburgh Town Council has just received from Dr Williamson, the chief sanitary and market inspector of the city of Edinburgh, an exhaustive report of the work done in his department since May last, at which time the department was constituted, nine of whom were employed in making door-to-door inspections in quest of insanitary conditions while the remaining four had been devoted their time to inspection of dairies, bakeries, and lodging houses, and to the carrying out of the provisions of the Factory and Workshop Shop Hours Acts, and Food and Drugs Acts. 10 of the present staff hold certificates in sanitary science and most of the others were preparing to obtain these. The greater part of the work of the department had consisted in inquiry into complaints regarding nuisances of a general nature. During the year 1894 cases of overcrowding had been discovered. The worst cases of overcrowding had partly to be found in the fact that there was not a sufficient supply of small houses with low rents but it was also due to the character of many of the inhabitants of the slums in whose case nothing but compulsion and the dread of heavy penalties would be efficacious in preventing the nuisance. The number of common lodging-houses in the city was 33, with accommodation for 2829 lodgers. There were 1239 workshops and 215 bakeries.

of which latter 162 were undergoing In 278 cases notices had been served for the cleansing of workshops. Landlords were rapidly on the increase, being now 55 in number. On and attempts were being made to diminish the warth of dampness of the atmosphere in them. Under the Road and Drugs Act, of 77 samples which were procured nearly 50 per cent. were of doubtful quality or adulterated. As regarded the Margarine Act, it had been found that great difficulty existed in carrying out its provisions. The number of ice-cream shops seemed to be somewhat on the increase. There had been closely supervised. The chief objections urged against these shops were of a moral nature and the Inspector had become impressed with the desirability of closing them earlier in the evening and if possible on Sundays. There were 468 dairies at present on the register in the city and in most of these the conditions had been found satisfactory. Of the 230,000 animals slaughtered during the year 523 carcasses had been condemned and seized in the slaughter-house, the predominant disease being tuberculosis. Over 6000 visits had been paid to butchers and other shops during the year. Attention had been also directed to the filthy condition of the boxes in which fat were conveyed to the city. The weekly fat stock sales had been regularly supervised and 11 live animals affected with tuberculosis had been seized. Every byte in the city was inspected once a fortnight. The Inspector had recently thought it necessary to draw the attention of the Council to the dangers which might result from the use of milk from recently castrated cows and special attention was at that time directed to the difficulty of supervising the milk supply from such animals during their stay in the cattle market. From inquiry in other districts he had found that the matter had not hitherto received the attention which it deserved.

Death of John May, M.D., F.R.C.P., F.R.S. Edin.
At Edinburgh on the morning of May 15th Dr John May died at the advanced age of 91 years. Dr May's father, a naval surgeon, was taken prisoner in the Napoleonic wars and was imprisoned in Verdun, where his wife joined him and where the son was born. After the release of the parents the father settled in practice in Edinburgh, where his son John began the study of medicine. Dr John May graduated in 1828 as Doctor of Medicine and became assistant to Professor Hamilton who was Sir James Simpson's predecessor in the Chair of Midwifery in Edinburgh University. After Professor Hamilton's death and before the appointment of Sir James Simpson Dr May conducted the classes His practice in the city was a large and high-class one and until a few months before his death he still retained some of his patients. Dr May was the father of the Royal College of Physicians of Edinburgh and had occupied the positions of President of the Obstetrical Society and of the Medical-Chirurgical Society. He was the only surviving original member of the Medical Missionary Society. Dr May was twice married and is survived by a widow, two sons, and two daughters.

Death of James Rae, M.D. Aberd., of Stirling
The death took place at Stirling, on May 15th, of Dr James Rae, retired surgeon, who was a survivor of one of the Arctic expeditions in search of Sir John Franklin. He saw most of his service in the navy and at one time held the post of Deputy-Inspector General of Hospitals and Fleets. Since his retirement from practice his time has been largely spent in microscopic investigations.
Professor Cottar Ewart's Experiments
At the monthly meeting of the directors of the Highland and Agricultural Society held in Edinburgh on May 1st and interest in horse breeding reported that they had visited Penicuik and that they recommended the great scientific committees suggested that the experiments should be conducted with powers to propose to other bodies that they should join with the Highland Society in contributing to their continuance for some years. The report was adopted and it was recommended to a sub-committee to arrange for an exhibition by Professor Cottar Ewart of his hybrid horses at the show of the society which was to be held in Edinburgh in July.
Aberd. Hospital Saturday
The committee in charge of this movement have arranged

for a demonstration to take place in Dublin Park on June 24th. A detachment of the New South Wales Lancers who lately arrived at Aldershot from Australia will take part in the sports and the proceeds from the gala are expected to be increased thereby.

Aberdeen Parish Council and the Vaccination Question

No allowance for the "conscientious objector" is made in the Vaccination Acts for Scotland and the Scotch Local Government Board have again intimated to the city parish council, who have assumed a defiant attitude, that unless a distinct assurance is now forthcoming that defaulters will immediately be prosecuted the Board will proceed against the parish council as previously instructed. The parish council, however, have—but by a majority of one vote only—resolved to adhere to their former resolution, which was recently referred to in the columns of THE LANCET.

The Health of Aberdeen

The measles epidemic in Aberdeen seems now to be nearly over, the number of fresh cases reported for each of the past two weeks having been only 26. The epidemic has been perhaps the most widespread which has occurred in the health history of the city. During January of this year there were 1647 cases with 25 deaths, in February 2177 cases and 34 deaths, in March 1996 cases and 45 deaths, and in April 497 cases and 20 deaths, being 7.8 of the total mortality for the month. Last week 11 fresh cases of diphtheria and 11 of typhoid fever were reported, being an increase on the preceding week, and there have lately been two sporadic cases of small pox, one in Aberdeen itself and another a little beyond the city boundary.

May 16th.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Health of Dublin

OWING doubtless to the prevailing easterly winds the number of cases of lung disease is at present greater than usual. At the last meeting of the Managing Committee of Cork street Hospital held on May 11th the registrar reported that the number of cases of pneumonia admitted during the last month was much above the average, though few of them had proved fatal. The number of cases of diphtheria had also increased.

The Richmond District Lunatic Asylum

The last meeting of the governors of the Richmond Asylum took place on May 11th when votes of thanks were passed to the medical superintendent, Mr. Conolly Norman, and to the other members of the medical staff.

Legacies to Dublin Hospitals

The late Mr. James Wear recently left by his will large legacies to various hospitals and charitable institutions in Dublin and its vicinity. The total sum—£120,000—is to be divided among certain institutions fixed upon by the Vice-Chancellor as being included within the terms of the will, the proportion to be allotted to each being left to the absolute discretion of the three trustees under the will.

Belfast Asylum

On the occasion of the last meeting of the board of governors of the Belfast Asylum (May 8th) under the old régime (in future the management will vest in a committee of the city council) the medical superintendent, Dr. Graham, read a very interesting report. Referring to the old board he said that they deserve every praise for the recognition of the fact that the aim of alienists to-day in the treatment of the insane is to get them away from all excitement and noise and to place them in buildings in suburban districts, surrounded with pleasant foliage and green fields. Such an opportunity has been given by the foresight of the governors in the purchase of the magnificent demesne of Purdysburn for the insane of Belfast. Under such conditions as exist there improvement must be more rapid and permanent, especially in the morose and melancholic cases. Patients who in the narrow confines of the old asylum had to be watched will at Purdysburn enjoy a more healthful freedom. In the recognition of such facts the late board of governors has shown

how progressive its members were. It is, as Dr. Graham points out, the duty of the new board to provide accommodation for those mentally ill. They have the opportunity of building an asylum which shall be a modern hospital for the treatment of brain diseases. The patients must be given every chance of recovery—that is, they must be placed where excitement is avoided, freedom of movement allowed, occupation available, and hygienic laws observed in their fullest extent. In a word, an asylum is a hospital for diseases of the brain and Dr. Graham sketches how such an institution should be constructed. The old asylum is quite out of date. No mental cases should be placed in workhouses as formerly was done in Ireland. Further, a colony must be established for that most unfortunate class of patients—epileptics. To confine such people, who except when the fit is on are often refined, honest, and willing to do what work is possible, is a relic of the past inhuman treatment of the mentally afflicted. Dr. Graham refers to the existence of such colonies in the United States and at Chalfont St. Peter in England. Finally, Dr. Graham speaks of the importance of the after-care of discharged patients who are often homeless and helpless. They need the care of friends and the oversight of a physician and he recommends the formation of an unobtrusive association of ladies to look after the needs of such cases. Dr. Graham's report, from which I have culled a few points, is of great interest. Free from the usual statistics of such often bald reports, it is suggestive, eloquently written, and has been received most favourably by the public. It is to be hoped that every one of the new board of governors will carefully study its contents.

The Belfast Corporation Bill

A curious hitch has arisen in connexion with the new Bill which the corporation is at present promoting in reference to Clause 43, which seeks powers by which the corporation may compel owners of small houses to establish proper sanitary facilities in their properties which have no back passages. It refers specially to the 20,000 houses in Belfast which were allowed to be built without back passages. The clause as drawn would allow the corporation, if it thought fit, to lend the owners of such property part of the money required to establish proper sanitary conveniences. Lord Morley, it appears, has so amended the clause as to make it apply only to houses erected after the passing of the Act and, further, has so altered it as to make it compulsory on the corporation to advance on loan two-thirds of the cost of the alterations ordered. These alterations would make the clause of no effect, as it must be, to be of any good, retrospective. The Parliamentary agents of the city corporation have advised that the clause should, under the circumstances, be dropped, but at a meeting of the corporation held on May 3rd it was decided to refuse to take this advice or to yield to Lord Morley's amendment.

Belfast Board of Guardians

At a meeting of the Board of Guardians of Belfast held on May 9th the assistant clerk made an announcement which has astonished the unfortunate ratepayers. It would appear that in estimating the expenditure for the year ending March 31st, 1900, they started with a deficit of £9000. This is astounding, considering that a supplemental rate (which, indeed, the unfortunate taxpayers could never very clearly understand) of 5d. in the £ was made in order to give the new board a clean sheet on April 1st. Out of the £9000 there were £1100 to be deducted as the balance of sanitary accounts which were not adjusted by the Local Government Board, £2483 from Parliamentary grants, £600 from workhouse buildings for which a loan was in progress of negotiation, £100 which the Veterinary Department owed them in respect of salaries, and £87 in respect of the hospital, the total being £4400. That left £4600, but a great deal of it could be explained by the regrettable epidemic of typhoid fever. With reference to the lunatics the assistant clerk said that the corporation had not seen their way to take the preliminary steps to save the ratepayers £2000 a year. If they had taken over the lunatic department of the house they would be entitled to a capital grant of 2s. a week. That stood as a positive loss to the ratepayers of £2000. The Finance Committee of the City Corporation of Belfast have been considering this urgent matter. It means that the total requirements of the Belfast Poor Law Union for the year ending March 31st, 1900, will be £93,721 6s. 3d. This has to be raised by the three county

two observers have been enabled to try the process on a large scale and they were also greatly helped by an engineer, Mons M X Gosselin. The ozone is discharged into a tower built of masonry where it comes into contact with the water circulating in the tower. A previous filtration has eliminated the grosser forms of impurity. All pathological microbes are destroyed, the only microbe which resists being the bacillus subtilis. This microbe, though harmless to man and other animals, possesses extraordinary powers of resistance, being unaffected by steam under pressure at a temperature of 110°C. By this process no foreign element is introduced into the water which can have any prejudicial effect on the health of persons who may afterwards use it. On the contrary, owing to the increase in the amount of nitrates and the diminution in the quantity of organic matter, water treated by this method is less liable to future contamination and is consequently less liable to alteration.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Medical Women

THE German Federal Council has decided to admit women to the State examinations in medicine, dentistry, and pharmacy. It was mentioned by me on a former occasion¹ that according to current rumour the question would be settled in connexion with the forthcoming alterations in the State examinations, but the Federal Council without waiting till the new regulations came into force has resolved that women may be admitted at once and under the present regulations. Moreover, the Council ordained that when in any German university the rules and by laws did not contemplate the matriculation of females the curriculum classes attended by them as exceptional students (*Gast hörer*) were to be counted to them as if they were fully matriculated students. Undoubtedly the above decree is the most important of all the steps hitherto taken in this matter, but there are still some difficulties to be overcome before female medical students can fully profit by their new privilege. The curriculum includes a good many lectures, practical courses, &c., to which women have hitherto not been admitted by the respective professors and the Federal Council has no authority to compel the members of the Faculties to admit them. There is no possibility of passing the State examination without having worked in the dissecting room, and in Berlin, for instance, the professor of anatomy (Dr Waldeyer) has declined to allow female students to work together with those of the opposite sex. He considers that there should be special courses of anatomy for females, and until such courses are instituted female students in Berlin will not be able to produce certificates of a full curriculum. Thus and other obstacles will for the present prevent the overcrowding of the medical faculties by women, but it is certain that the removal of the last barrier is only a question of time.

The Practitioners' Association

The annual meeting of the delegates of the Practitioners' Association (*Ärztvereins Bund*) was held this year in Dresden, Dr Aub of Munich, the president of the association, being in the chair. The members were welcomed on behalf of the State and the municipal authorities and it was noticeable that the president in replying to the address of the representative of the Prussian Government rather ironically said that the meeting was very much obliged to the Government for its kindly words, but that the delegates of the German practitioners would rather hear of Governmental measures by which the condition of the medical profession might be improved. The principal subject of this year's proceedings was the "free-choice system" (*freie Arztwahl*) in sick clubs which has been already described in these columns.² This system has been introduced in a good many clubs to the chagrin of their medical officers and to the great satisfaction of the younger medical men who had not been fortunate enough to obtain club appointments. It has, however, been a

great drawback that the system of medical aid in these clubs was variable and depended entirely upon the will of the committee or upon the general meeting of the clubs so that in one year the free-choice system and in another the system of appointed medical officers with fixed salaries might be in force, the consequence being that the medical men engaged in club practice under any of these systems were never sure how matters might turn out next year. One group of medical practitioners therefore desired that the free-choice system might be made compulsory by law, whilst others were of opinion that it would be better left to agreement between the medical men and the clubs. After a very long and animated discussion the meeting adopted a resolution to the effect that the clubs ought to be compelled by law to admit every practitioner desiring to engage in club practice, that contracts between clubs and medical men ought to be controlled by the medical chamber, that persons with incomes of more than 2000 marks (£100) ought not to be admitted as members of workmen's clubs, and that no unqualified man ought to be allowed to give medical attendance to club members. This resolution was passed by a great majority, 107 delegates voting for and 29 delegates against the motion. The discussion on unqualified practice which had been placed on the order of the day was postponed till next year's meeting.

A New Medical Journal

A new medical weekly—the *Deutsche Ärzte Zeitung*—made its appearance on May 1st. The editor, Professor Stadelman, formerly of Dorpat, now of the Urban Hospital, Berlin, said in his inaugural article that the journal was designed to meet the requirements of the medical practitioner and that great attention would be paid to treatment. The first number contained articles by Professor Gerhardt on Trousseau and Dumontpallier's Reaction, by Professor Harnack on Poisoning by Arsenic, a Pharmaceutical Review by Professor Kobert, a Clinico therapeutical Review by the Editor, a letter from a New York correspondent, &c. The new journal is nicely printed.

Administration of Chloroform in the Street

A curious event—the administration of chloroform in a public place—happened lately in Berlin. A woman in a jump from an electric tramcar running at full speed through the Friedrich strasse fell and her right foot was caught between the platform and a wheel. Police and firemen made long but fruitless attempts to extricate the woman who screamed piteously. Medical help was then sought at the neighbouring university hospital, from which a surgeon and two assistants were sent. The surgeon decided to administer chloroform in order to facilitate the work of rescue and did so in the busy thoroughfare and in the presence of a great crowd. The tramcar was raised with lifting jacks and when after more than an hour the woman was released from her terrible position with comparatively slight contusions the surgeon was loudly applauded by the spectators.

ROME

(FROM OUR OWN CORRESPONDENT)

Professor Cervello's Treatment of Tuberculosis Pulmonalis

RETURNING to this theme, briefly and imperfectly handled in my last letter, I can now, by way of supplement, give further and fuller details as to its "previous history" and present position. Dr Cervello has for many months past been studying the action of the formic aldehyde (in familiar parlance "formalina") on the tuberculous lung. He disclaims priority in the use of this agent in such cases. In fact, he admits that the formic aldehyde, so far from being a novelty in therapeutics, had been tried by other investigators in search of a cure for tuberculosis. Their experiments, however, proved abortive or worse, that agent being a powerful irritant, causing even painful reactions in the respiratory apparatus healthy or diseased. How to conserve its remedial virtues while minimising, if not absolutely excluding, these deterrent reactions? This was the question Dr Cervello set himself to solve. His first step was to blend the formic aldehyde with air—with *un ambiente medicato* (a medicated atmosphere)—in the required proportions. For this he contrived a special

¹ THE LANCET, March 11th, 1899, p. 731.

² THE LANCET, Feb. 2nd 1895, p. 317; July 13th 1895, p. 127; July 18th, 1896, p. 218.

apparatus which he calls "rapomgeno," the use of which maintains in varying proportions the evaporation of the formic aldehyde without the necessity of constant surveillance. The "rapomgeno" having turned out a success, his next step was to render the formic aldehyde tolerable if not entirely grateful to the sufferer. This involved pharmacological difficulties neither few nor small, but at last he succeeded in obtaining a new compound of the formic aldehyde to which he gave the name of "gazolo" (or less colloquially "igazolo"), which answered all the conditions. The report evolved by this compound soon becomes quite tolerable by the respiratory organs, its imbalanced action of taking or reading aloud easily—a result impossible under the formic aldehyde *per se*. The first two steps gained Dr. Cervello next experimented clinically with his "igazolo." Naturally he would have preferred to begin with tuberculous cases at as early a stage as possible so as to give his medicament the fairest chance. Instead of this he had to commence operation on the inmates of the Gradenigo Hospital for Consumption in all of whom tuberculous pulmonary had for some time been running its course. Making the most of the circumstances, beginning moreover as previously stated in the dead of winter (Jan 15th), he faced every adverse condition—the *quintessence opulenta* (hospital environment), the regulation diet, not always modified to his liking and, indeed, comparatively meagre, the tendence and general resistance non troppo *irregolare* (not too constancies)—and all this notwithstanding, he attained results far beyond his anticipations. As stated in my previous communication, of the 26 patients experimented on 10 cured absolutely were presented as such to the Palermitan Accademia delle Scienze Mediche of which Dr. Cervello is president, and were pronounced on examination by the experts of that body to be *guariti*. Nine were almost cured their delirance from the disease being only a question of time, two were "improved," sensibly, one was stationary, two had got worse, and two died. The last were admitted to hospital in an advanced stage of the disease, with *diffusions miliarium*, grave hemoptysis, or *localization interlobar*, which of the diseases would have a fatal issue, although even in their case the "igazolo" treatment did work a notable amelioration in the long run. All things considered Dr. Cervello, after the first course of his chemical experiments, felt justified by his 40 per cent. of cures to follow up his method confident that under better conditions and at a less advanced stage of the disease a yet higher percentage is probable. Pharmacologically speaking, he finds a microbicidal virtue in the "igazolo" peculiarly well adapted to tuberculous. It not merely destroys the bacilli—an only partial benefit, as even dead the bacilli (according to Strass) can exercise a pernicious influence—but it has an exceptionally high oxidizing power, and to this its curative action is due. The "igazolo," in fact, does in a more energetic fashion what hyper-oxygenated fresh air has from all antiquity been found to do in phthisis pulmonalis. But to let Dr. Cervello conclude in his own words, as given in his memoir, read before the Palermitan Accademia: "In a disease like tuberculosis which we are accustomed to regard as nearly always fatal, and which has resisted the most powerful forms of clinical attack devised by the most powerful intellects, I confess that it was not without tepidation that I decided to cultivate the scientific calm which is true preventive of every possible source of error and, what is more, I have tried to keep myself extraneous to that affection (*cegarismo*) which does on its own offsprings and which I have succeeded and I therefore wait with due secrecy the criticism of my colleagues." All that Dr. Cervello claims, it will be seen is to have "made out a case" for further experiments with "igazolo." As stated last week, he has been enabled by the munificence of a local millionaire to prosecute these under conditions much more favourable than those presented by the Gradenigo Consumption Hospital, while yet another result may spring from their prosecution so assisted—they may attract not arrive on the day expected but on the next day—a Saturday—at about 11 A.M. She was allowed to walk from a cab to the ward and her admission was not reported to the resident medical officer till midnight when she was in a dying condition. She died at 9 A.M. on Sunday without being seen by any of the honorary staff. An inquiry was held and revealed the following state of affairs. The hospital

MONTREAL

(FROM A CORRESPONDENT)

A Sad Case

I medical circles and among the laity, too, a general subject of conversation for the last few days has been a Montreal matrimonial disaster of the utmost sadness—the removal of a patient's sound eye by mistake for the diseased one. The patient, a young man of 18 years, had received an injury to the left eye some five years ago, which had been treated by the operator, an eye specialist of good reputation and of considerable experience in private and hospital practice. A few days ago the injured eye became troublesome and inflamed, and its removal was recommended. Consent was given and the surgeon attended with a medical assistant and nurse at the home and enucleation of an eyeball was effected under anaesthesia. The friends were informed that it was satisfactorily accomplished. A few minutes later the double discovery was made that the sound eye had been removed. So strange an accident is fortunately of extreme rarity but not unique, as a similar case has been reported as having occurred in the United States.

The Battle of the Clubs

Club practice had received a good deal of attention from the governors of the College of Physicians and Surgeons, our provincial medical rulers, and it had been proposed to discipline members who undertake contract medical work. At the last annual meeting there was such an upheaval and canvassing and tactics worked on local issues, that the matter of club practice has dropped out of sight and will not be brought up again for a long time. It is estimated that over one fourth of the medical men of the district are interested in club or society work. The great power of the members of the benefit societies has been shown in municipal elections and in the dropping of officers, in one case after 30 years' service, who had expressed views opposed to club methods. The usual honorarium to the surgeon is 4s per head per annum, medicine is also furnished.

Interprovincial Registration

Up to the present time a medical graduate of one of the provinces could not practise in any other province without re-examination and re-registration. The awkwardness of this state of things has been manifest ever since Confederation was consummated 32 years ago and efforts have been made from time to time to evolve a scheme whereby one examination would do for the entire Dominion but without success. Professor T. G. Roddick, M.D., a member of the House of Commons, is now working energetically on a plan the main feature of which is the creation of a central board of examiners composed of representatives of the provinces who should hold an examination annually at the capital, Ottawa, and grant diplomas entitling the recipients to practise in any part of the country. Dr. Roddick has addressed numerous meetings of medical men in different sections of the Dominion and has met with much encouragement. The various provinces are strong on their "rights" and the difficulty of securing combined action is that of the creation of a Canadian University for the sole purposes of examining and the granting of diplomas and degrees.

May 8th.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

Neglect at the Women's Hospital, Melbourne

The confidence of the public in the arrangements of the Women's Hospital, Melbourne, has been a good deal shaken lately. A patient suffering from peritonitis was sent to the hospital by one of the honorary medical officers. She did not arrive on the day expected but on the next day—a Saturday—at about 11 A.M. She was allowed to walk from a cab to the ward and her admission was not reported to the resident medical officer till midnight when she was in a dying condition. She died at 9 A.M. on Sunday without being seen by any of the honorary staff. An inquiry was held and revealed the following state of affairs. The hospital

is divided into two departments—the midwifery, under the control of a resident and assistant resident medical officer, and the infirmary under the charge of a separate resident medical officer. The last-mentioned, Dr Docker, was away on leave and the midwifery resident, Dr Crowley, was undertaking his duties as well as his own. The sister in charge of the nurses in the infirmary department was also away on leave. On the Saturday the patient arrived Dr Crowley went out for the afternoon, leaving Dr Stanley, his assistant resident on the midwifery side, in charge of both departments. The patient arrived at the hospital before Dr Crowley went out, but her admission was not reported to him by the nurse in charge of the ward. She tried to find him after he had gone out and in some inexplicable manner failed to find Dr Stanley who was in the hospital all day. Dr Crowley returned at 7 P.M. but was not informed then of the patient's admission. He went out again and returned at 11.45 P.M. and went round the wards and found the patient in a dying condition. It is a rule of the hospital that the wards shall be visited at 8 P.M. by the resident and also that he shall not be absent from the hospital for a longer period than six consecutive hours, but it appears that these rules have not been observed for a long time. The nurses contradicted each other in their evidence and appeared to have lost their heads. The committee thought fit to place all the blame on Dr Crowley who has resigned. The inquiry, however, showed a great want of system in the arrangements of the hospital for the admission of patients, the attendance of the medical officers, and the responsibilities and control of the nurses, a want of system for which the committee itself is responsible.

The Friendly Societies and the Medical Profession in Victoria

The various friendly societies, such as the Grand United Order of Oddfellows, the Manchester Unity Order of Oddfellows, the Sons of Temperance, and the Australian Natives Association, have just been holding their annual conferences in Victoria. The reports showed that in all of these bodies the sick pay had exceeded the amounts previously incurred and that the financial position of the friendly societies was not altogether satisfactory. The action of the Medical Defence Association in calling a conference on the relations of the medical officers to the societies came in for criticism and the general feeling of the members who spoke was distinctly hostile to the proposals of the Medical Defence Association and especially to the idea of excluding from lodges men earning over £200 per annum. It was said, and always is said, by the lodges that if the present medical officers went on "strike" and refused their services to the lodges plenty could be got to take their places, showing that their grievances could not be very great. It is a curious anomaly that members of friendly societies who are also for the most part members of trades unions should make use of such an argument, but it shows the necessity for all members of the profession to join associations like the Medical Defence Association in Victoria and practically to adopt the tactics of the trades unions and to fight the friendly societies with their own weapons.

The New South Wales Board of Health

The report of the Board of Health of New South Wales for 1897 has been laid before Parliament. The report states that with reference to the notification of infectious disease it had been thought best to limit the operation of the Act to diphtheria, typhoid fever, and scarlet fever. In designing the machinery for carrying out the provisions of the Act the objects kept in view were the following—

To record medically certified cases alone, to secure prompt notification to local authorities, to cause local authorities to record it and then to promptly transmit the information to the central bureau there to distribute all cases to the districts to which they rightly belonged and once a fortnight to show on a diagrammatic map how many cases of each disease had occurred in each police district and in each municipal district within it and the deaths which had been thus caused.

In relation to the supervision of dairies a good deal of discontent had arisen among dairymen owing to the Board advising the local authorities to see that the provisions of the Act were more stringently enforced, and the local authorities had not all equally complied with the advice and hence a good deal of the feeling of dissatisfaction. During the year seven cases of illness were reported to the Board under the Leprosy Act, 1890. It was found that three were cases of leprosy and the remainder were other diseases. Two of the cases of leprosy were admitted to the lazaret, and the third patient, who had recently arrived from Queensland,

was allowed to return home. All were whites—one of native and two of foreign birth.

The Geelong Water supply

Dr Gray, assistant medical officer to the Board of Public Health of Victoria, has furnished a report on the water-supply of Geelong. He finds that the river water in the vicinity of the intake of the supply is grossly polluted by discharges from mills and other establishments and bacteriological examination showed the following result: "The approximate average number of micro organisms per cubic centimetre, growing in gelatin in 90 hours at 70° F., was in No 1 sample, 12,200, in No 2 sample, 4600, in No 3 sample, 4800, and in No 4 sample, 11,000." He concludes that the water is so contaminated as to be utterly unfit for human consumption.

Delay in Erecting an Infectious Disease Hospital, Melbourne

At the time of the Queen's Jubilee funds were subscribed in Melbourne for the erection of an infectious disease hospital. A site has been granted by the Government, but nothing further has been done. The urgent need of such an institution was well illustrated by a recent case. A woman and child were staying at a boarding house in the city and the child was taken ill. The medical attendant was not sure whether it was diphtheria. The landlady of the boarding-house refused to allow them to remain there. The private hospitals are not allowed to take in infectious cases and those applied to refused. The public hospitals also were unable to take in the child, and finally a private hospital agreed to take the child in. The Board of Health then inquired into the matter with a view of prosecuting the proprietors of the private hospital for breach of the Act. Ultimately the case proved not to be diphtheria. The responsibility for the delay in connexion with the Infectious Disease Hospital rests with the committee. The secretary states that the amended plans and specifications will be submitted for consideration of the committee in a few weeks.

Children's Hospital, Melbourne

The new wing of the Melbourne Hospital for Sick Children was recently opened by His Excellency the Governor. The whole of the buildings are fitted up in accordance with the most recent scientific methods and as part of a scheme for an entirely new hospital.

Alleged Cruel Treatment of a Patient at the Melbourne Hospital

A patient at the Melbourne Hospital recently accused one of the resident medical officers of improper and cruel treatment. He alleged that he had been bitten by a snake but the medical officer suspected malingering and applied the electric battery, when the man confessed he was shamming. The committee investigated the complaint very carefully and fully exonerated the medical officer, Dr Douglas Shields and found that he did not subject the patient to unnecessary suffering.

Queen Victoria Hospital for Women

The following have been appointed honorary consulting medical officers to the Queen Victoria Hospital for Women, Melbourne: Surgeons Sir T. N. Fitz-Gerald, Mr F. D. Bird, and Mr G. A. Syme. Physicians Dr D. Grant and Dr John Williams. Gynecologists Mr R. Adam and Mr M. A. O'Sullivan. Children's specialists Surgical, Mr H. Russell, Medical, Dr R. R. Stawell.

April 10th.

Obituary.

HENRY BENDELAACK HEWETSON, M.R.O.S. Eng.

MR. BENDELAACK HEWETSON died on May 13th in his fiftieth year. For some few years past the deceased gentle man had been ailing and several attacks of influenza aggravated his condition. In March last he broke down and after staying at the village of Essington, near Hull, was removed a fortnight ago to the latter town where he has just passed away.

Mr Hewetson was born at Beverley and while still a youth went to Leeds, where the family took up their residence near Woodhouse Moor. The foundation of his education was laid at the Beverley Grammar School and subsequently he joined

THE LEEDS GRAMMAR SCHOOL. In 1668 he entered as a student at the Leeds School of Medicine and in 1673 he qualified as a member of the Royal College of Surgeons of England. He then entered the Royal London Ophthalmic Hospital and became clinical assistant to the late Sir William Bowman. Having studied aural surgery at Guy's Hospital he was offered the position of house-surgeon at the Royal London Ophthalmic Hospital, but preferred to return to Leeds, where he commenced practice and acted as assistant surgeon to the Leeds Public Dispensary and in the same year was appointed one of the honorary ophthalmic and aural surgeons to the Leeds Infirmary, which position he continued to hold up to the time of his death. He also held the position at one time of honorary consulting ophthalmic and aural surgeon to the Regent's Hospital, Williamham, and honorary surgeon to the Leeds Public Dispensary. Among his contributions to medical literature are "The Human Eye in Perfection and in Error," "Relation between Sick Headaches and Optical Defects chiefly Astigmatic, near Diagnosis and Treatment by Glasses," and "The Localisation of Headaches." To medical journals he was also a frequent contributor, but his literary labours were not confined strictly to medical subjects. "The Influence of Joy upon the Workman and his Wife" and "The Life and Works of Robert Hewetson, Boy Farmer and Poet," being two of the best known lay labours from his pen.

Mr Hewetson was a Fellow of the British Laryngological Association president of the Otolological Section at the British Medical Association meeting in 1893, and a member of the Ophthalmological Society of the United Kingdom and of the Leeds and West Riding Medical-Chirurgical Society. He was also a member of the Society of Otolaryngology, Laryngology, and Rhinology of Paris.

The deceased surgeon was a man of catholic tastes and broad sympathies. In everything relating to art he took a great interest and was himself an artist. He was a traveller and collector of objects of art and gave to the Leeds Philosophical and Literary Society's Museum a small but valuable collection of Egyptian antiquities from Old Alexandria and Cairo. In 1885 he was elected President of the Leeds Naturalists' Club and Scientific Association and held that position for three successive years. As an ophthalmologist he did much good work, especially in regard to the study of migration. He also assisted in the exploration of the famous "Kitchen Middens" in the Holderness district of East Yorkshire. Mr Hewetson leaves a widow and 11 children, for whom much sympathy will be felt.

On May 6th there passed away one of those country practitioners of whom "Ian MacLaren" has written so feelingly in "A Doctor of the Old School." George Geddie was for 40 years a practitioner in Garmouth, Morayshire, and was notice in the *Aberdeen Herald* says, "generous to a degree all the qualities that constitute the ideal type of character and unsparingly self-sacrificing he unmistakably possessed a Justice of the Peace for the county and was for many years a member of the Speymouth School Board. Some six years ago he was presented with a purse of sovereigns in recognition of his valuable services to "three generations of men, women, and children in a wide and populous district." He leaves a widow, three daughters and two sons, one of whom is following his father's profession in Australia.

Deaths of the following eminent foreign medical men are announced—Dr Marcelino Duran, formerly Director of the French Naval Medical Service—Dr Ury, head of the Ophthalmic Clinic, Bordeaux—Dr H. Thomas, Clinical Professor of Medicine in the Tours Medical School.

The annual festival dinner in aid of the funds of the East London Hospital for Children was held on Monday night in the Whitehall Rooms Hotel Metropole, under the presidency of the Duke of Connaught. The festival donations, amounting to £2255

ROYAL COLLEGE OF PHYSICIANS OF IRELAND—At a stated meeting of the College held on May 12th the following gentlemen were admitted on examination—

Licentiate in Medicine and Midwifery—George Cole Baker M.B. and J. J. McGrath, L.R.C.S. Irel.

Licentiate in Medicine—G. H. Brand, L.S.A. and J. O. McWalter, L.R.C.S. Irel.

Licentiate in Midwifery—A. H. Hardcastle, L.S.A.

ROYAL COLLEGE OF SURGEONS IN IRELAND—**DENTAL EXAMINATION**—The following gentleman having passed the necessary examination has been admitted a Licentiate in Dental Surgery of the College Mr W F Crosse. The following gentlemen have passed the primary part of the examination for the Licence in Dental Surgery Mr A L Harrison, Mr D L Rogers, Mr J R Small, Mr M Sterling, and Mr E N Tate.

THE LATE MR A H REINHARDT—The death of Mr A H Reinhardt, M.R.O.S. Eng., L.R.O.P. Lond., L.S.A., occurred on May 6th, at 135, Hornsey road, N., from cardiac failure occurring in the second week of enteric fever. The deceased was 33 years of age and was in active general practice in Holloway up to the time of his illness a fortnight ago. He had been in Holloway four years, having previously practised in the neighbourhood of Battersea-park. He was educated at the Yorkshire College and the London Hospital Medical School. He possessed an exceptionally powerful and muscular physique and was in robust health until the commencement of his illness. The body was cremated at Woking on May 9th.

CHARING-CROSS HOSPITAL—A bazaar in aid of the building fund of Charing cross Hospital will be held in the Albert Hall on June 21st and 22nd under the patronage of the Queen, the King of the Belgians, the Princess of Wales, Princess Christian, and other royal ladies, several of whom have graciously promised to be present during the proceedings. The arena of the hall will be covered over with a platform upon which stalls will be arranged to represent different countries. A book is being prepared as a souvenir of the bazaar and will be illustrated by artists of the highest repute, amongst whom are the greater number of the Royal Academicians. Communications and offers of help for the Swiss stall may be addressed to Mrs Kitto, St Martin's Vicarage, Charing cross, W.C.

BRISTOL ROYAL INFIRMARY—The annual distribution of prizes to the students of the Bristol Royal Infirmary took place on May 9th. Sir Charles Cave, Bart., occupied the chair and made the presentations, of which the following is a list—Entrance Scholarship, Mr H Gough and Mr P Maxey (£10 10s each), Supple Medical Prize and Gold Medal, Mr James Phillips, Supple Surgical Prize and Gold Medal, Mr J R Frost, Olark Prize, Mr P G Stock, Tibbitts Memorial Prize, Mr J R Frost and Mr E M Pearse, Pathological Prizes, Mr J R Frost and Mr J Phillips, Ophthalmic Prize, Mr P G Stock, Dental Prize, Mr S Wilcox, Special Dental Prize, Mr J L Tilly, and Special Midwifery Certificates, Mr J R Frost, Mr H Hemsted, Mr W B Prowse, and Mr P G Stock.

LITERARY INTELLIGENCE—Mr Henry Kimpton of High Holborn announces the publication of a work entitled "Progressive Medicine." It will be published in four volumes every year at intervals of three months and will be copiously illustrated. In the words of the prospectus it will "present in an original, narrative form a clear statement of the practical advance made in every department of medicine and surgery during the year, each specialty being dealt with by a single authority." The general editor is Dr Hobart Amory Hare and the subscription for the four volumes to be published every year is £2 10s.—For some years past Mr F J Hanbury, F.L.S., of the well known firm of Messrs Allen and Hanburys, has been engaged upon a work dealing with the flora of Kent, assisted by the Rev E S Marshall, F.L.S., vicar of Milford, Surrey. The book has just been published and contains besides an account of the flora notes on the topography, geology, and meteorology of the county. The price is 12s. 6d. net and orders may be sent through any bookseller or direct to Frederick J Hanbury, Plough court, Lombard street, London, E.C.—Messrs William Green and Sons, of St Giles street, Edinburgh announce the publication of an *Encyclopædia Medica* in 12 volumes to be issued quarterly. The price per volume is 20s. or if the series is subscribed for now 17s. 6d. Orders must be sent before

June 15th. The general editor is Dr Chalmers Watson. A supplementary volume will be issued from time to time so as to keep the book up to date and with each will be given small gummed marginal labels which can be placed opposite the article affected in the original volume. For example, one label would run "Abscess, for further information see Supplement, p. 130." The agents in London are Messrs J & A Churchill, Great Marlborough street.

THE TRUSTEES OF SMITH'S CHARITY have sent a donation of £100 to the Royal Hospital for Diseases of the Chest, City road, E.C.

ROYAL ALBERT HOSPITAL, DEVONPORT—As a result of the bazaar recently held in aid of this hospital the sum of £715 has been forwarded to the institution.

MEDICAL MAGISTRATE—Mr R E E South, L.R.O.P. Lond., M.R.O.S. Eng., has been appointed a Justice of the Peace for the Borough of Boston, Lincolnshire.

BRISTOL JUBILEE CONVALESCENT HOME—Her Majesty the Queen has given a conditional promise to open the Bristol Jubilee Convalescent Home in November or December. This institution has been erected on the Clifton Downs at a cost of £90,000 as a Jubilee memorial.

PRESENTATION TO AN ARMY MEDICAL OFFICER—At a fête recently held on the premises of the Borah Mosque, India, Major R J Geddes, M.B. Glasg., of the Royal Army Medical Corps, was presented with an address a gold watch, a silver plate, and a despatch box, in recognition of the valuable services rendered by him to the Borah community in India during the plague epidemic. Major Geddes was in charge of the plague hospital and segregation camp for about six months. His skill and energy were manifest at the time by the fact that out of 49 patients admitted to the hospital no less than 32 recovered. It is a rule in the service that no presentations are to be made to any officer, but from the exceptional circumstances of this case the authorities relaxed the rule to allow the natives of the district to show their esteem and appreciation of Major Geddes's services.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Scotch Parish Council Medical Officers

MR. ALEXANDER CROSS has introduced into the House of Commons a Bill to give an appeal to the Local Government Board to the medical officers of parish councils in Scotland.

Sale of Food and Drugs Bill

This Bill having now been dealt with by the Grand Committee on Trade goes before the House of Commons for the report stage and Sir Charles Cameron will take this opportunity of bringing forward his proposal for the appointment by the Local Government Board of a Standing Committee of Reference on Food Standards.

HOUSE OF LORDS

TUESDAY MAY 16TH.

Isolation Hospitals.

The Earl of LICHFIELD at this sitting of the House moved the second reading of the Bill introduced by him to amend the Isolation Hospitals Act of 1893. His lordship explained that it had been assumed that where efficient hospitals were in existence built under the Public Health Act of 1875 with the assent of the local authority and the Local Government Board they might be transferred to the new local bodies and that the county councils might contribute to the expenses if they so pleased. Unfortunately the Local Government Board had decided in neither of these cases was it legal so to do, and thus the operation of the Act of 1893 was seriously crippled. There was, indeed, a deadlock existing in many counties. The Bill was introduced with the assent and support of the County Councils Association of England and Wales, who were anxious that a change should be made in the law as speedily as possible. The Bill gave power to district councils and joint boards to transfer hospitals to county councils and it allowed county councils to contribute towards the expenses of the county councils to under the Act of 1875. Power was also given to the county councils to borrow—a power which they did not possess under the Act of 1893. Lord HARRIS said that the Local Government Board were not quite satisfied approving of some of the provisions of the Bill, were not quite satisfied as to the provision enabling county councils to take over existing hospitals.

The Bill was read a second time.

London Water Question

In the course of the consideration in committee of the whole House of the Metropolitan Water Companies Bill a clause was inserted providing that "Nothing in this Act shall authorise the construction by any

he bought the article in the same state as sold and with a warranty His amendment was based on the recommendation of the Select Committee on the Adulteration of Food Products and was, he said, justified by the experience of the Margarine Act which accepted an invoice as a warranty.

Mr WALTER LONG said that while no doubt the Select Committee had passed a recommendation of this kind they added a proviso that there should be a limit as to the time during which the warranty should run in the case of goods in bulk and perishable articles and it was for the present Committee to consider whether it was practicable to insert such an amendment and what its effects were likely to be if it were inserted. His hon. friend had told him that by a subsequent amendment he intended to make the wholesale dealer a party to the prosecution, but when he came to that proposal his hon. friend would find practical legal difficulties in the way which he would be unable to overcome. It must be remembered that the fraud which was to be the cause of action was created by the sale on the part of the retailer to some customer of an article which turned out to be fraudulent. The wholesale dealer was not a party to that sale and could not be made a party to it by any process known to the law at present. It was proposed to bring him in because in another sale he had delivered to the retailer an article which afterwards turned out to be adulterated. As he was advised that was a proceeding which it would be impossible to incorporate in the Bill. The experience of the Margarine Act had been quoted, but he would ask the Committee to remember that that experience was limited to butter and margarine which involved simple questions as compared with those involved in the many other articles covered by the Sale of Food and Drugs Acts. Another point to consider was that if an invoice was to be regarded as a warranty something would have to be added to it and with that addition made he would like to know what became of the distinction between an invoice and a warranty. After a due consideration of all the circumstances he asked the Committee to reject the amendment on the ground that it would weaken the procedure under which it was hoped to discover offenders and successfully prosecute them. He was firmly convinced that any attempt to shift the responsibility from the person who was a party to the transaction to someone who might be behind him would weaken the administration of the Acts.

Mr ASCHOFF said that not only did he support the principle of the amendment, but he wished to see it extended.

Mr KEARLEY reminded the Committee that there was more fraud in connexion with butter and margarine than any other articles and argued that if an invoice could with safety be accepted as a warranty under the Margarine Act there would be little risk in so accepting it under the Sale of Food and Drugs Acts. Without such an amendment as this, they made the retailer responsible for the dishonesty of the wholesale dealer an injustice for which he felt sure that Committee would not stand sponsor.

Mr PARKES expressed the view that they must get at the wholesale dealer if they hoped to do any good by this legislation.

Mr HEYWOOD JOHNSTONE said he believed that this proposal would not work. The answer to what had been put forward in its support was why did not the retailer ask for, and insist upon, getting a warranty? If they carried this amendment they would have absolved the retailer altogether, and he objected to that most emphatically.

Sir CHARLES CAMERON intimated that he would vote for the amendment though he thought it did not go far enough.

The SOLICITOR-GENERAL (Sir Robert Finlay) said that in some cases an invoice might be a warranty but in most cases it was not. In the former cases the remedy would be by independent proceedings against the person who had given the false warranty. He was not going to say anything about the merits of this amendment what he did say was that in its present form it was very objectionable.

After some further discussion the amendment was carried by 20 votes to 16.

On the motion of Mr WALTER LONG the following words were inserted at the end of the first sub-section—viz.: And has also sent a like notice of his intention to such person. The person by whom such warranty or invoice is alleged to have been given shall be entitled to appear at the hearing and to give evidence and the court may, if it thinks fit, adjourn the hearing to enable him to do so.

Mr R. G. WEBSTER moved to add these words which he regarded as consequential upon the decision come to by the Committee—viz.:

And unless he shall summon before the court the person upon whose warranty he so relies. If the defendant shall be discharged from the prosecution under Section 25 of the Sale of Food and Drugs Act the prosecutor shall be entitled to proceed forthwith against the person so giving the warranty as aforesaid, and if it be proved that such warranty was false the person so giving the same shall be guilty of an offence under this Act and shall be liable to the penalties mentioned in Section 14 of this Act.

Mr WALTER LONG suggested that the hon. Member might withdraw this amendment now and leave the whole subject to be put into proper form during the report stage. It was possible that the course the Government would take to carry out the decision of the Committee might be different from the words he now proposed but at all events if he withdrew them now the Government would deal with the matter as a whole on the report stage.

The amendment was by leave withdrawn.

An amendment moved by Mr. KEARLEY to exclude foreign warranties was rejected by 25 votes to four.

On the motion of Mr BARTLEY the following words were added to the clause viz.: Where the defendant is a servant of the person who purchased the article under a warranty or invoice he shall, subject to the provisions of this section be entitled to rely on Section 25 of the Sale of Food and Drugs Act, 1875, and Section 7 of the Margarine Act, 1877, in the same way as his employer or master would have been entitled to do if he had been a defendant, provided that the servant further proves that he had no reason to believe that the article was otherwise than that demanded by the prosecutor.

Clauses 18 (duty of court to send articles for analysis) and 19 (provisions as to certificates of analysis) and the supplemental clauses having been agreed to the Committee adjourned.

FRIDAY, MAY 12TH.

The Committee met again to-day for the consideration of the proposed new clauses.

Sir CHARLES CAMERON moved to insert in the Bill this clause, viz.: "When an employer is charged with an offence under this Act he shall

be entitled, upon information duly laid by him, to have any other person whom he charges as the actual offender brought before the court at the time appointed for hearing the charge, and if, after the commission of the offence has been proved, the employer proves to the satisfaction of the court that he has used due diligence to enforce the execution of the Sale of Food and Drugs Acts, 1875 to 1899, as defined by this Act, and that the said other person had committed the offence in question without his knowledge, consent, or connivance, the said other person shall be summarily convicted of such offence and the employer shall be exempt from any penalty." The hon. Member explained that the clause was copied from the Margarine Act and helped to carry out his proposition that in all these matters there should be similar treatment.

Mr WALTER LONG said he hoped the Committee would not adopt the clause, for he believed, in spite of the fact that the Margarine Act contained a similar clause, that it would weaken and in fact break down the administration of the Act. It would be impossible to recover penalties if the master were free in the manner proposed to put the blame upon the employé who might very well be a young lad earning only a few shillings per week. The only safe course in his opinion was to adhere to the old principle which made the master responsible for the acts of his servant. It was true that it had been departed from in the case of the Margarine Act, but he would remind the Committee that the clause was inserted in one of the final stages of the Bill in the House of Lords and for himself he must say that he was sorry the House of Commons did not reject the provision.

Mr BARTLEY supporting the clause, said that justice demanded its insertion in the Bill.

Sir CHARLES CAMERON said that so far as he knew there had been no complaint about the operation of the clause in the Margarine Act and asked the President of the Board of Agriculture to remember that in this case they were making people liable to imprisonment and not merely to civil consequences. The principle of the master being responsible for the act of his servant did not apply to criminal liability.

Mr R. G. WEBSTER contended that it would be absurd to imprison a man when he had shown that he had no intent to defraud and had taken adequate precautions against fraud.

Mr T. W. RUSSELL said that there was a broad distinction between the Margarine Act and the Sale of Foods and Drugs Acts, for while the former dealt with such matters as packing, branding, lettering &c., the latter dealt with the much more serious affair of adulteration. Such being the case, he thought it would be extremely dangerous to adopt this clause from the Margarine Act.

Mr JOHN BURNS opposed the clause on the ground that it offered a bad precedent for other legislation in connexion with coal mines and workshops and other matters.

Mr HEYWOOD JOHNSTONE said that 70 per cent. of the defences under the Margarine Act were the innocent and simple-minded assistant just up from the country who knew nothing about margarine and he contended that the proposed clause would put a premium upon this class of assistant.

The clause was rejected by 20 votes to nine.

On the motion of Mr BARTLEY the following clause was inserted in the Bill, viz.: "1. For the purposes of the Sale of Food and Drugs Acts the expression 'food' shall include every article used for food or drink by man other than drugs or water, and any article which ordinarily enters into or is used in the composition or preparation of human food and shall also include favouring matters and condiments. 2. The definition of 'food' contained in Section 2 of the Sale of Food and Drugs Act, 1875, is hereby repealed."

On the motion of Mr KEARLEY this clause was inserted, viz. Any person who wilfully obstructs or impedes any inspector or other officer in the course of his duties under the Sale of Food and Drugs Acts, or by any gratuity, bribe, promise, or other inducement prevents, or attempts to prevent, the due execution by such inspector or officer of his duty under those Acts shall be liable on summary conviction for the first offence to a fine not exceeding £20, for the second offence to a fine not exceeding £50, and for any subsequent offence to a fine not exceeding £100.

Mr KEARLEY moved to insert a clause in the following terms, viz.:

Any inspector appointed by any local authority or by the Local Government Board under this Act shall have power: (a) At all reasonable times to enter any private or public sale room occupied or used by merchants, brokers, wholesale dealers, or other persons, and any public or private warehouse, factory store, quay shed, ship or barge where food or drugs are offered for sale or deposited for the purpose of sale or carriage, and to purchase, seize, or procure samples of any such food or drugs (b) to purchase, seize or procure samples of any food or drugs at the time of delivery or at any railway station or other place during transit or upon the premises of or elsewhere in the possession of any person for the purpose of carriage." He was advised he said that inspectors must have this power conferred upon them if they were to put down a system of fraud which was carried on to a very considerable extent.

Mr WALTER LONG submitted that the clause went too far in the direction of interference and assured the Committee that before introducing the Bill the Government had considered very carefully what powers were necessary for the proper and effective administration of the Act.

After a debate of some length the clause was rejected by 25 votes to six.

Mr HEYWOOD JOHNSTONE moved to insert: "After the commencement of this Act no milk containing less than three and a half per cent. by weight of butter fat shall be sold, or exposed or offered for sale under the term 'prime milk' and any person acting in contravention of this section shall be liable on summary conviction to a fine not exceeding £20."

Mr WALTER LONG while sympathising with the object of those who had framed the clause, said he could not regard it as practicable and therefore he must ask the Committee to reject it.

The clause was rejected by 33 votes to one.

Sir WILLIAM HOULDSWORTH moved to insert: Where a sample of milk has been taken in the district of any local authority for the purpose of analysis by the analyst of such district the local authority shall at the request of the person from whose milk such sample was taken cause other samples to be taken, either within or without such district of milk from the same consignor and shall submit such samples to the same analyst and if it shall appear that such analyses

BOOKS, ETC., RECEIVED

Expositio.

Successful applicants for Vaccinator, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to their Local Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

NASH, JAMES T O M.B. C.M. D.P.H. has been appointed an Assistant in the Bacteriological Department of King's College London.

N.B.—A fee of 5s is charged for the insertion of notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers

To Correspondents.

EDITORIAL NOTES

It is most important that communications relating to the editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written or one side of the paper only, and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising department of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used

MANAGERS' NOTICES

TO SUBSCRIBERS.

With subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newspapers (with none of whom have the Proprietors any connection whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularly in the despatch of their journals and an earlier delivery than the majority of agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are—
For the United Kingdom
One Year ... £12 6
Six Months ... £6 3
Three Months ... £3 2
Subscriptions (which may commence at any time) are payable in advance

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. In cases higher rates are being charged, on the plea that the heavy weight of the LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweighted foreign issues, and agents are authorized to collect, and do so collect from the Proprietors the cost of such extra postage. The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

CHARTER-CROSS HOSPITAL.—P.M. Mr. Wallis Demonstration of Surgical Cases. (Post-Graduate Course).
THE HOSPITAL FOR SICK CHILDREN (67, Ormond-street, W.C.).—P.M. Mr. Pitts Demonstration of Selected Cases.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—P.M. Mr. H. Lloyd Williams Treatment of Fractured Jaw.

MASSAGE THE REAL AND THE SPURIOUS

WE have received the following letter from a properly taught masseur who no doubt has suffered as all genuine masseurs have suffered by the practices which have been carried on under the name of massage—

Re MASSAGE.

To the Editors of THE LANCET

SIRS,—In view of the recurring massage scandals should not something be done in the way of registering those who practise massage and should not all massage establishments (if there must be such establishments) be duly licensed? And also should not something be done in the way of requiring a minimum knowledge of their art by those so registered?—say a two years' curriculum to embrace anatomy, physiology and pathology and mechanics (chiefly animal mechanics) with training in practical massage work including a knowledge of its physiological and therapeutical uses and effects and the education of the hand, if besides they are required, or undertake under the guidance of the medical man to apply electricity to the human body that they should have a proper training in that branch of science then, lastly that it should be made illegal for anyone to practise massage except under the supervision or by the recommendation of a duly qualified medical man, as is mostly done already by all right-minded and respectable masseurs and masseuses.

I am, Sirs yours faithfully,

A MASSEUR.

This is not the first communication of its sort that has reached us and there is no doubt that the questions raised are of considerable interest to the medical profession. Massage and applied electricity are valuable agents in medical treatment, and it is intolerable that the public should be to a great extent deprived of their benefits because a group of unscrupulous quacks or infamous procurers have wrongfully described their proceedings under one or both terms. It reflects nothing but discredit upon our state and municipal legislation that it should have been possible for these persons so long to have kept up the pretence of ministering to the health of their clients when in reality they were pandering to their vices. We do not suppose that the medical profession has suffered in the least from the assumption of medical titles by persons like "Dr" Hill Wilson—though it is none the less an unfortunate circumstance that they should have attempted their imposition so long with impunity—but the genuine masseurs and masseuses, as well as the attendants who can undertake to carry out the details of electrical treatment—who comprise a class of most valuable assistants to medical service in a variety of conditions—undoubtedly have been severely injured by the ill-deeds wrought in their names. No young woman has publicly announced herself as a masseuse for the last year or two without knowing that some persons will consider that she is simply a *fille de joie*. To a certain extent the male masseur has fallen also into disrepute. A large section of the public, again, forego such treatment if possible even when ordered it. They know what "taking a course of massage" has too often meant of late and do not care to run the risk of putting into the hands of their friends and neighbours disgusting suspicions. Under these circumstances it is not surprising that we should have already received several communications in the spirit of the one which we print above, and before making further comment upon it we wish to say that all right-minded and respectable masseurs and masseuses have our best sympathy in the disagreeable predicament in which they have been placed by the supineness of municipal government.

With regard to a proposal for registering the persons who practise massage we do not think the proceeding necessary. Of course if registration were deemed advisable it would follow that a minimum of knowledge would be required from the registered, or rather it would be to ensure such a minimum of knowledge that registration would be enforced by law. But we do not think that there is any necessity whatever for registration because we cannot conceive anyone falsely pretending to practise massage who is not so pretending for immoral purposes and with such immoral persons the law should be able to deal, for we agree with our correspondent "A Masseur" that the public, as a rule, employ genuine masseurs and masseuses only under the supervision of a medical man and the medical man in this way protects them from the simple impostor. And on similar grounds we do not consider that there is anything to be gained by the licensing of houses as places of massage. The only institution that can pretend to be a place of massage and not be one is, as far as our imagination serves us, a brothel, and the municipal authorities have already discretion to deal with brothels.

Our correspondent's proposal that masseurs and masseuses should be registered will not find much support among the thoughtful, whether medical or lay. The registration of a body of men and women after a curriculum extending over two years and embracing the study of anatomy, physiology, and pathology would be a virtual repeal of the present Medical Acts. Who would keep such persons within the intended limits? It would follow to a certainty that a half-educated medical order would be instituted and would usurp medical practice in every direction to the detriment of the public health. It is quite sufficient that masseurs and masseuses should be able to satisfy the medical practitioner at whose suggestion the adjunct to treatment is being employed that the routine of massage is familiar to them—there is no necessity for them to be pathologists or diagnosticians.

IS IT QUACKERY?

To the Editors of THE LANCET

SIRS—Although it no doubt is right and proper that every person who practises the "Swedish Movement Treatment"—or what may perhaps be more scientifically called the Treatment of Disease by Therapeutic Exercises—should be a fully qualified medical man yet I think that Enquirer is rather hard on Mr T P von Braun because he wrongly (?) diagnoses what possibly might have been a somewhat difficult case of abdominal trouble. Congestion of the liver is an exceedingly vague term and is used very loosely both in the profession and outside it. However what I desire to emphasise is that in chronic diseases of the digestive organs as in chronic diseases generally with a few exceptions the treatment by therapeutic exercises is exceedingly useful and has succeeded where other methods of treatment have failed. In conclusion I beg to say that I am not acquainted with Mr von Braun either personally or otherwise.

I am Sirs yours faithfully

ORRO HOLST, M.R.C.S. Eng., L.R.C.P. Lond.

Eastbourne, May 17th 1899

THE CORPORATE AND MEDICAL REFORM ASSOCIATION

THE following is the list of subscribers to the Voluntary Fund raised by the Corporate and Medical Reform Association, Limited, to meet the expenses incidental to the presentation of their Memorial (see THE LANCET, May 6th, 1899, p. 1270), to the General Medical Council:—

"SUPERFLUOUS HAIR."

To the Editors of THE LANCET

SIRS,—As the result of the consultation which has been held in the columns of THE LANCET on "M.D." case it is clear that none of us is very much in favour of electrolysis as a means of removing the juvenile feminine moustache. The male advisers, all three of us, adopt a mildly coercive tone. I myself was for letting the patient severely alone, having framed the prognosis that in a case of this kind she would not do what in my view she ought to do. Mr Miller is for gently reasoning her out of her repugnance which, although strictly the right course is of very doubtful efficacy while "P J F K." is for mildly coercing the patient but "M.D." himself by telling him that it would "perhaps be wise for him to have a consultation in the usual way" although it is obvious that "M.D." prefers a consultation in the columns of THE LANCET. The only bright suggestion amidst these abortive proposals comes from one of the 15 lady M.D.'s of the University of London. This contributor joins the conference equipped with the faculty of intuition and a capacity of taking an all round view of the situation and she aims at not the best thing, but the best thing that is practicable—namely, by giving the patient, through peroxide of hydrogen, a prematurely white and therefore less conspicuous moustache. The suggestion is altogether novel and is well worth weighing. Chloride of lime would do the same thing but it is extremely irritating to the skin. Peroxide of hydrogen (as Dr Ethel

EXAMINATION OF THE CLAIMS MADE FOR CREATION, OR, PROPER AND IMPROPER BURIAL, WITH AN

By SIR FRANCIS SEYMOUR HADEN, F.R.C.S. ENG.

THE present communication is intended to be in no way controversial, in 1875—nearly a generation ago—it will be recalled by some, and necessarily forgotten by many, that I wrote certain letters to the *Times* in depreciation alike of the serious but readily removable abuses which distinguish our cemeterial system and of the dangerous and wholly insufficient resources of cremation as a suggested substitute for it. To-day, without the least intention of reviving a discussion which, in the face of combination, the establishment of the advertisement, and the methods of the newspaper, I have found to be useless, I do nevertheless desire—and that in the columns of a press which is alone competent to deal with the subject on its technical side—to leave behind me such an epitomised version of my share in the matter as I care to be permanently identified with. I had hoped to be able, to do this without any reference whatever to the statements which cremation relies upon to advance its interests. I have not found that possible. Some sort of visible connexion between the statements made on one side and the other has proved to be necessary to an intelligible comprehension of either of them, and this all the more, that while some of my own have been both written and printed, others of them, though written and sent to the press, have not yet been permitted to see the light. I have therefore fore taken care to preface each pronouncement of my own by the cremationist statement which called it forth, and of course to reverse the order of precedence when the state that my object in choosing the present moment for this final record of my views has been the delivery by Dr. G. V. Poore of the Allotey Lectures, and their reproduction both in the *Lancet* and the *British Medical Journal*. For some such summary of the scientific aspects of the case—though hardly expecting it to come in my own time—I have in a sense been long waiting. I had, of course, not seen the lectures or had any knowledge of the form they would take, and it, now that I have seen them, I find myself venturing to take exception to certain details of terminology which appear to me to impair their value. I may say at once that such details in no way affect the authority of their conclusions with which I will be seen I am heartily in accord. Nor am I, it may be duly stated to find those conclusions, while the conformity of my own views, altogether out of harmony with the alarming pronouncements of the *Times*. I have nothing, however, to say against the *Times*. My relations with it have been of the very best all my life and they are not likely to alter now because it happens to have changed its editor and the editor the views of the paper.

On Jan 12th, 1875, I wrote in the *Times* as follows—
"I am sorry, the apostle of cremation tell us, in substance it is not in its own country and in fact, horrible in principle, a violation of the dead and a member to the living. In a way of publication mode of information or any possible abuse which they recognise as having crept into the practice of dissection it is but the practice itself, the like, in fact, that the dead are little more than the normal stuff buried and that by the impossibility of interment in the like, interment as a practice is rendered all but nugatory, and as a practical deposit of the remains of the dead they are left upon this surface and in fact, upon no other ground found their repository of cremation."

THE CASE FOR PROPER BURIAL

"The case for proper burial may be thus summarised:—
1. The majority of all civilised bodies that have lived and that die on the earth surface is the earth."
2. The earth is supposed to be inseparable from the principle of life, and the independence of that principle and of our own creation, and the life of the earth is to be found not in the burial of the dead, but in the life of the earth which is to be kept in such a way that the earth (after the life) can have no access to them."
3. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
4. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
5. To seek to prevent the necessary agency of the earth by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
6. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
7. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
8. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
9. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."
10. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."

1. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."

2. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."

3. The earth is supposed to be inseparable from the resolution of the body by the agency of the earth, of which we are composed, and that the earth is competent to effect that resolution and to effect it innocently."

PROPER AND IMPROPER BURIAL, WITH AN
EXAMINATION OF THE CLAIMS MADE
FOR CREMATION.
BY SIR FRANÇOIS SEYMOUR HADEN
F.R.C.S. ENG.

THE present communication is intended to be in no way controversial. In 1875—nearly a generation ago—it will be recollected by some, and necessarily forgotten by many, that I wrote certain letters to the *Times* in depreciation alike of the serious but readily removable abuses which disfigure our cemeterial system and of the dangerous and wholly unsatisfactory resources of cremation as a suggested substitute for it. To-day, without the least intention of reviving a discussion which, in the face of combination, the attraction of the advertisement, and the methods of the newspapers, I have found to be useless, I do nevertheless desire—and that in the columns of a press which is alone competent to deal with the subject on its technical side—to leave behind me such an epitomized version of my share in the matter as I care to do this without any reference whatever to the statements which cremation relies upon to advance its interests. I have not found that possible. Some sort of visible connection between the statements made on one side and the other has proved to be necessary to an intelligible comprehension of either of them, and thus all the more that while some of my own have been both written and printed, others of them, though written and sent to the press, have not as yet been permitted to see the light. I have therefore taken care to preface each pronouncement of my own by the cremationist's statement which called it forth, and of course to reverse the order of precedence when the fact happens to have been the other way. I may also state that my object in choosing the present moment for this final record of my views has been the delivery of Dr. G. V. Poore of the Mayo Lectures and their reproduction both in *THE LANCET* and the *British Medical Journal*. For some such summary of the essential aspects of the case—though hardly expecting it to come in my own time—I have in a sense been long waiting. I had, of course, not seen the lectures or had any knowledge of the form they would take, and it, now that I have seen them, I find myself venturing to take exception to certain details of terminology which appear to me to impart their value I may say at once that such details in no way affect the authority of the conclusions with which I am heartily in accord. Nor am I, I trust, unduly elated to find those conclusions, while the contrary of my own views, altogether out of harmony with the alarming proportions of the *Times*. I have nothing, however, to say against the *Times*. My relations with it have been of the very best all my life and they are not likely to alter now because it happens to have changed its editor and the editor upon this subject are inferior in the principle of judgment and

On Jan 12th, 1875, I wrote in the *Times* as follows:—
"Intention, the apostle of cremation tell us, in substance it is not terms and speaking of it in the most comprehensive sense, as requiring in fact, and effected in fact, horrible in practice, a violation of the dead and a danger to the living. In a variety of publications which have excited much attention they denounce not any particular mode of interment or any particular abuses which they recognize as having crept into the practice for dissection it is but the practice itself. They take no notice of the fact that the dead are little more than the earth that should resolve them of such metals as wood, lead, brick and the like, interment as a principle is rendered all but nugatory and as a practice deprived of its raison d'être. Finally they leave to be inferred, since they give us no hint to the contrary, that the evils thus created are inferior in the principle of judgment and upon this inference and upon no other ground found their recommendation of cremation."

THE CASE FOR CREMATION.

On Jan 12th, 1875, I wrote in the *Times* as follows:—

"Intention, the apostle of cremation tell us, in substance it is not terms and speaking of it in the most comprehensive sense, as requiring in fact, and effected in fact, horrible in practice, a violation of the dead and a danger to the living. In a variety of publications which have excited much attention they denounce not any particular mode of interment or any particular abuses which they recognize as having crept into the practice for dissection it is but the practice itself. They take no notice of the fact that the dead are little more than the earth that should resolve them of such metals as wood, lead, brick and the like, interment as a principle is rendered all but nugatory and as a practice deprived of its raison d'être. Finally they leave to be inferred, since they give us no hint to the contrary, that the evils thus created are inferior in the principle of judgment and upon this inference and upon no other ground found their recommendation of cremation."

knew there existed no ground whatever for any such statement, that by common consent typhoid fever owed its convection to overcrowding, filthy surroundings, squalor, starvation, and the actual contact of one poor unwashed, fever-stricken skin with another—in a word, to infection, or contagion, or both," and if I had seen at the time Dr Poore's Milroy Lectures I might have added of diphtheria "(1) that its bacillus had not as yet been recovered from the soil, (2) that out of 30 collected examples of soil from areas likely to be infected not a single bacillus typhosus had been found in one of them, (3) that according to Koch and Loesner it had, in fact, never yet been found outside the human body, and (4) that, so far from being found in the earth, 'virgin soil' so called was fatal to it."

All infectious diseases, I declared divide themselves into two great groups or classes—one which derives its origin from surface water as a carrier of the morbid agent the other from actual contact of one case with another in the open air. Again the first of these classes is itself subdivisible into two distinct types of disease—one which depends on putrescent vegetable exhalations from marsh lands, and which includes within it all those forms of febrile disturbance known as malarial the other which like cholera and choleraic diarrhoea, depends on the actual introduction into the intestinal canal by means of surface water of the *defæca* of patients affected with the same disease. Burial, therefore, four feet below the soil can have nothing whatever to do with any of those forms which constitute, as I have said, the first class of infectious disease. The second, and by far the larger class again, and which comprises small pox measles, whooping-cough typhus, scarlet fever, diphtheria, &c. owes its propagating power to the actual contact or close contiguity in the open air of one patient with another. That class, therefore has no connexion with either soil or water and being wholly independent of even the surface of the earth can have even less to do with burial than the first class. To lump these two classes together therefore, as to help cremation, is now being done is to begin with a scientific solecism of the most glaring kind, and seeing how perfectly well known the superficial method of their propagation is to suggest that they are spread when buried below the surface is a statement to all appearance in the nature of a direct appeal to popular ignorance and credulity. The zymotic death-rate, in fact, has nothing whatever to do with burial, only two out of the seven diseases which comprise it having ever been shown to depend in any way whatever either on soil or water.

THE "TIMES" AGAIN!

Meanwhile as if determined not to give up its unsupported statement of Dec 22nd, 1897, the *Times* on April 12th, 1898, printed a letter from Sir Henry Thompson which contained the following story—

THE STORY OF THE BURIED COW

"Pasteur's success in dealing with anthrax is known to all. Pasteur proved that the earthworms brought up the spores and not the bacilli themselves, which soon disappear from the buried corpse after the event. These spores long retain their vitality and unless the body is cremated or is buried in a large quantity of quicklime the disease will sooner or later appear when a favourable nidus presents itself. Pasteur examined the surface mould at the spot where two years before a cow dead of anthrax had been buried at the depth of seven feet and observed germs which by inoculation produced anthrax in a guinea pig. This is an illustration and amply suffices here, as one among the various ways in which 'innumerable seeds of pestilence are sown broadcast through the land, a sentence characterised by my critical friend as inflated phraseology' but it has at least the merit of being strictly true."

SIR SEYMOUR HADEN'S COMMENTARY ON THIS STORY

"Pasteur did not 'prove' that earthworms brought up from a depth of seven feet the spores of anthrax; (1) because worms do not commonly burrow to such a depth and (2) because the buried bacilli of anthrax do not live long enough in the earth to form spores. The bacilli here referred to, like moulds, fungi, and other plants of low organisation require for their growth carbon and nitrogen water also and a certain temperature are necessary for the maintenance of their vitality. Like plants, also, by the disintegration of organic combinations containing nitrogen they produce certain chemical products and as fungi assist fermentation. They vary too, as to the amount of atmospheric air they require, some of them, like the bacteria of anthrax, being unable to maintain their vitality without it and some being able to do with little (the so-called aerobic and anaerobic bacteria of Pasteur). Like other plants again, some are reproduced by spores or seeds. When by a linear arrangement of their primitive cells bacteria grow like rods they are called, as everyone knows, bacilli. Anthrax is a bacillus of this kind and being, like *bacillus septicus*, which is called aerobic dwindle and dies when deprived of air. If therefore, the body of an animal which has died of anthrax is buried and left—that is, without being opened—the bacilli which characterise this form of disease die with it, and notwithstanding statements to the contrary not only die with or very shortly after, it, but are incapable of reproduction in an active form. The infection of anthrax cannot in fact, as cremationists declare, be spread when so buried. When therefore it has been reproduced in fields in which cattle infected with the disease have grazed, died, and been buried the fresh outbreak is owing not to the buried carcass, but to the spores which have been left by the *defæca* of the infected animals upon the surface of the field in question. Both Klein and Koch are well agreed as to this and Koch in addition has proved by direct experiments that the spores of anthrax are not, as Pasteur has stated taken up by earthworms and deposited on the surface by their castings and that the spores of anthrax bacilli, when mixed with earth in which worms are present, are not taken up by these creatures at all. Klein, indeed, carries these

statements further and says: 'If bacilli grow in the depths of a fluid medium—in a medium that is, but scantily supplied with air—they do not form spores, and at length degenerate, and, as the fluid dries up, this degeneration goes on till finally nothing is left of them but their debris. Such bacilli, of course, are quite innocuous when introduced into the tissues of animals or into fresh nourishing media.' Those, therefore, who have followed me in this statement—a statement examined, re-examined, and confirmed by the most eminent men to whom I have submitted it (and, as I have since understood admitted by Pasteur himself)—will see how little reliance can be placed on the reports spread broadcast through the land by the advocates of cremation that by the act of interment we shorten human life."

CREMATION AN ENCOURAGEMENT TO CRIME

I now, and I trust, for the last time, come to that part of the subject which no cremationist if he can help it is willing to hear mentioned, which the newspapers engaged in the cremationist propaganda are careful not to discuss, and which, whatever the momentary success which may attend (or appear to attend) the agitation of the question, will assuredly sooner or later provoke the repressive action of the law.

On April 25th, 1893, in his evidence before a Select Committee of the House of Commons, nominally on "Death Certification," but really largely employed to advance the interests of cremation, Sir Henry Thompson made the following admission (Q. 1125, 1139)—namely that, out of 393 bodies which he had up to that time burnt he had thought it prudent in "four or five cases" to take out and preserve the stomach kidney, spleen, and a portion of the liver. Why? He had previously told the committee that cremation, as he practised it, involved little or no risk, and the committee, as is proved by their report, had believed him. Why, then, these precautions? Well might one of its members ask. (1377-78), whether, if such an admission were "known" (no), it would not put an end to cremation altogether! I ask, is it known? Have the votaries of cremation the least idea of any such proceeding as a condition precedent to a participation in its benefits? Is it duly set forth as such in the "Mannual of Modern Cremation," which they are invited to depend upon as their guide? Has it occurred to them that in submitting the bodies of their friends and relatives to be thus dealt with they have one and all more or less identified themselves with these four or five suspected cases and that the day may come when, in the cause of justice, it may be necessary to obtain the names of those who thus figure as possible homicides? Why, again, confine these precautions to the detection of poisons, as if poison were the only weapon of the murderer? And *cui bono*, when, having burnt the body, a stab in the back or a knock on the head or a ligature round the neck is beyond the possibility of discovery? And, again, if in the early part of 1893 four or five suspicious cases out of 393 had already been burnt, how many more, may I ask, has it been considered prudent to put under lock and key since then when the number burnt amounts to 1283? Is it possible that any Government in its senses (on the report of a committee composed largely of cremationists) that with the special precautions taken by Sir Henry Thompson "there was little probability that cases of crime would escape detection, still, that inasmuch as such precautions were purely voluntary they ought in the interests of public safety to be enforced by law" Have they been enforced by law? Has the smallest notice been taken of this formal recommendation of the committee? None whatever. The destruction of evidence still goes on. That such a thing can be done with impunity by a self constituted private society would, if it were not a fact, be deemed incredible, and as such I respectfully bring it to the notice of the Home Secretary. Not—having once embarked in, so hazardous a business—that I blame the Cremation Society for taking adequate precautions against "accidents" But are they adequate? How can they be? That the Cremation Society has all along been fully conscious of the risks it was running is proved by its own offer to make a post-mortem examination of every body it burnt. Why did it withdraw that offer and adopt instead of it the disembowelling process I have described? By what process of ratiocination is it now satisfied with a certificate (given, it may be, by the murderer, as in the case of Dr Cross and Mr Palmer) and "verified" by a stranger to the case who, being called in to see the body, has nothing to go by but what the possible murderer chooses to tell him? That such a certificate is not worth the paper it is written upon is certain and that it would be so regarded in a court of

RADIOGRAPHY, WITH SPECIAL REFERENCE
TO THE DETECTION OF RENAL
CALCULI.

*Delivered before the Oxford Medical Society on Friday,
May 12th, 1899*

BY C MANSELL MOUTLIN, M.D OXON,
F.R.C.S. Ed.

SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL
 PRESIDENT OF THE ROYAL SOCIETY

(GENERALIZATION).—The first thing which I wish to do is to express to you my cordial thanks for the honour which you have done me in writing me to read a paper before the Oxford Medical Society on some of the problems of radiography. It was with much pleasure that I accepted the invitation so kindly sent me by your secretary, not only because of my long standing connexion with Oxford, but because of the great interest which I take in radiography and in everything which can assist its advancement. I do not think that it is necessary for me to say anything here about the nature of the Roentgen rays or as to their mode of production. There are many things in connexion with them which are still obscure, but it appears now to be generally acknowledged that they are either exceedingly short or very long wave lengths, either waves and that they are produced by the bombardment of the anode by the highly charged molecules which form the cathode stream (Other things being equal their brilliancy appears to depend upon the volume or the thickness of the spark and their penetration upon the force of the cathode stream—or in other words upon the hardness of the tube and the strength and the rate of interruption of the current.) Obstacles—referring the focus from which the rays emanate as small and as steady as possible and for this purpose as the products of what have been called paraffin tubes, should be cut off. Putting aside for the present the theoretical uses of the Roentgen rays, their importance so far as medicine and surgery are concerned is derived from more or less thoroughgoing through the tissues of patients and the power which these either waves or passages of rays may pass through or nearly all the rays may be absorbed, so that the screen upon which they are received is either brilliantly lit up or is almost dark. Success in radiography, so far as its practical application is concerned, they have to traverse so as to produce the greatest amount of contrast. They must, if possible, penetrate some of the tissues completely and others not at all. Nothing is more easy than to obtain a representation of a thin structure such as the hand. The screen or plate, which serves as the base of the apparatus, is comparatively small and the absorptive index of the tissues between the bone and the shadow upon the same plane is comparatively small and the outline is not blurred. The number of layers projected in successive of the rays after these have passed through and the outline of the rays is close to the bones, so that there is no interference of the rays as they pass through and the absorptive index of the tissues completely and others not at all.

[illegible]

to keep a dead body unburied; and (3) for the illegality of strong coffins, brick graves and vaults, and of all contrivances having for their effect to retard resolution; and to confer on the dead a tenure, practically illimitable, of the soil which is necessary to the purpose of the living.

THE MILROY LECTURES.

The importance of these lectures as the first utterance of the kind in affirming by the aid of personal observation and collected facts the principles for which I have been contending for so many years, and as dissipating the fallacies which for too long a time have been allowed to possess the uneducated ear, is so considerable that I can do no less than accord them a distinguished place in the final record I am now making. If in his evident desire to be judicially fair Dr Poore has somewhat attenuated the value of his own observations by giving undue prominence to those of others this cannot be chargeable upon him a fault. It is enough for the purpose of this record that he tells us in correction of the speculations of Sir Charles Cameron of Dublin that the bacillus of diphtheria, like that of enteric fever, has never yet been found in the soil, that the discovery of hæmatozoa in the blood has opened to us a new view of malaria as something altogether different from a soil disease, that the plague bacillus has never been met with beneath the surface, that it is not in the earth but in the air that we must chiefly expect to find the morbid particle (whatever that may be) and in the surface water which is its readiest carrier to the soil, and it may be a little but only very little below it, that the *dejecta* of the patient and the germs of anthrax and of tetanus, though found to have attained a lodgement within the particles of the earthy mass, form no part of its substance and lose all their virulence when once there. In a word, that the enteric fever referred to by Sir Charles Cameron, so far from having its *nidus* in the soil as, as I have stated, far more likely to have its origin in the actual contact, under conditions of filth and overcrowding, of one fever patient with another.

AD TERRAM

For myself, however—and I am not sorry to have an opportunity of making the statement here—I am disposed, in the absolute belief which I have in the soil as the final correctant of every form of organic decay—and even of disease—accruing in the course of nature to its surface, to go farther than Dr Poore and invest it with supreme power as such universal correctant—as the chief factor in the great cosmical design, in short—for this great purpose. Never, surely, was the cremationist farther at sea than when, in pursuance of his aims, he assumed the contrary and, with the aid of the *Times*, went out of his way to proclaim it *urbis et orbis*. "By the act of interment we literally sow broadcast through the land innumerable seeds of pestilence which long retain their vitality, &c., destined at some future time to fructify in premature death or ruined health to thousands." Such is the statement which, in presence of a world's population which is ever increasing and an individual duration of life which is ever extending, the public is seriously invited to believe, as if—for it means nothing less—the earth and its inhabitants were thriving on disease!

I can, in fact, see nothing more probable than that as water in the shape of rain is largely concerned in cleansing and washing the germs of disease out of the air, so the earth as the natural filter of such water is the ultimate cleanser and disinfectant of both. In a word, that its beneficent office in this respect is the very opposite of the malevolent office which is imputed to it by the advocate of cremation.

Here, however, I find myself under the necessity of parting company (though only for a moment) even with Dr Poore, seeing that, though we arrive at the same conclusions, we get at them by the aid of materials which are not the same, and by means of a language which does not convey the same thing to the educated ear. The point is an important one, because much of our misunderstanding of the power of the earth as a disinfectant has arisen out of it, and no small amount of capital hostile to its pretensions on this score has been manufactured out of it. In his lecture, for instance, Dr Poore expressly tells us

that, when he speaks of earth he means *humus*—that is, of the earth of his kitchen garden which is heavily laden with animal matter—while I have been making my experiments in the comparatively hungry soil of the park land which surrounds my house. In other words, while he has been burying animal matter in animal matter I have been burying it in earth which nearly approaches the condition of what is called "virgin soil." The results obtained by us are consequently not the same. My reason, however, for taking note of the difference is that while his proceeding represents "interment" in its worst form, mine represents it in its best, his in the form which I have especially condemned and which is in fact made the groundwork of the cremationist objection to burial, mine in the form in which burial ought to be, and might be, carried out if cemeteries were only properly managed.

The language, again, which he employs, and which is that only too commonly used by the bacteriologist, is from my point of view objectionable because it encourages the popular belief that the body, even when properly buried, instead of re-entering the atmosphere insensibly and in every way inoffensively, is beset by a sort of nondescript borderland saprophytic fauna whose office it is to devour it—a reading, which, the cremationist of course goes out of his way to encourage, and which is really materially helped by the use of such terms as "the living earth" to signify nitrification, and of such a word as "hatched" to signify the germination of the saprophyte, which, I take it, in common with Dr Poore, is at best an organism little higher than the lichen or the fungus. Nor am I attaching too much importance to a carelessness of terminology which I believe began with Pasteur, because, while it imposes upon the popular ear, it is not without its effect even on our own—an effect which, in fact, is demonstrable. When Dr Poore, for instance, digs down into the humus in which he has buried a rabbit and finds it "full of earwigs" even he derives, *ipso facto*, a sort of warrant for his terminology, while I, digging into my own graves, which I do once a year to determine the progress of nitrification, and finding nothing of the kind, not unnaturally take exception to it. I have also another reason for objecting to it in the fact that 17 years ago, when bacteriological science was comparatively young, I wrote a letter to a late very distinguished friend on the subject which, though only half serious, will even now bear repetition.

38, Hertford street, Mayfair
December 18th, 1882.

MY DEAR GULL,—I am glad to observe that what I have called the bacterial bugbear is beginning to moderate its pretensions as a general alarmist. Not that I disbelieve in germs and other entities equally occult and speculative, which by a pretty free use of Pasteur's term are being employed to shake our faith in the plan pursued by Nature for the resolution of dead matter since the world began. All I say is that, without being in a position either to affirm or deny the existence of these aggressive germs and the harm they are said to do I should like to hear something of the friendly germs and the good they do. If it should come to be proved which is possible, that the great operations of Nature destructive as well as constructive are carried on by germs all I can say is that I am prepared to think as highly of germs as I do of chemical action or of any other of those forces, physical or vital, by which Nature is pleased to work. I object however to their employment as missiles. I object to hear them spoken of as if they were creatures which prey upon us and to have them hurled at us as *Nemeses* for our misdeeds when really all we know about them is that the work they do is very like the work of ferments such as the yeast plant and other vegetable products of a similar character. I will be bound to say that if at this moment we canvassed public belief upon the point we should find nine-tenths of it in terror of all microbes not as plants, but as predaceous animals the more formidable that they are invisible to all but the expert and that if we swallow them as perfume we must, it is in the hope that by doing so we sterilise them—which, in fact, in 999 cases out of 1000 I fully believe we do.—Yours,
F SEYMOUR HADEN

The reappearance of this letter in connexion with the Milroy Lectures reminds me, however, of another thing which has amounted to a profession of faith with me for many years and which I observe has not escaped the acumen of Dr Poore—the recognition, I mean, of the inherent power of the individual to resist, against the heaviest odds, the convection of disease—a power evidently immeasurably greater than that either of the so-called omnipresent microbe or of the artificial bacillus, however carefully it may be cultivated. I cannot but think, with every respect for the praiseworthy efforts of the bacteriologist to track the morbid particle to its lair, and master it there with its own weapons, that room still exists for a larger faith in those provisions of Nature for our individual protection than we are altogether willing to accord to them. If it is really a fact that, with every drop we drink and

has the above I see without surprise an announcement in Medical Journal of March 25th that at no distant period we means of a limited liability company (1) it is proposed to fully equipped crematorium in the near neighbourhood of by by.

putting this into practice. The position of the patient is of great importance. If he is sitting upright, the stone is but little influenced by the respiratory movements, and this is, of course, a great disadvantage, as it is impossible to obtain a definite shadow unless the object is fixed. But in the abdomen as in all full one the liver is crowded down on to the front of the kidney and the antero-posterior diameter of the body increased. I prefer the patient to be recumbent with the back well arched. The light should be passed through in both directions, from before backwards, with the screen of the anterior abdominal wall is increased, the front of the abdomen is flattened as far as it can be, and the liver is lifted to some slight extent from off the kidney. The influence on the respiration is not so great as it is in the antero-posterior position, and the calculus may be counteracted by an ingenious device contrived by Mr Mackenzie Davidson. The patient is directed to hold his breath for so long as he conveniently can, and the exact duration of the thorax is noted by means of suitably placed pointers. Then he is allowed to breathe until he has recovered himself when he is directed to hold his breath a second time with the thorax in exactly the same state of distension. This is repeated as often as necessary the light being only switched on during the period of apnea when the thorax is at rest and the kidneys and the calculus are presumably occupying exactly the same position relatively to the light. As the total exposure has been shortened by Mr Mackenzie Davidson down to one minute it is not so difficult for the patient as it might be supposed.

With regard to biliary calculi I have very little to say. They are even more difficult owing to their very low frequency in those cases in which the inflammation is most needed—when for instance, the calculus does not lie in the gall bladder but in the common or the hepatic duct and when the patient is stone and middle aged. The best chance of success is placed on the patient in the dorsal position with the back rounded, and with the feet raised above the head. The abdominal wall is thus elevated and the pressure of the abdominal contents which exerts pressure on the gall bladder is removed. The patient is stone and middle aged and firm.

This is not of so much value for renal calculi, as the distance of the stone in the pelvis of the kidney from the last rib or the transverse process of one of the lumbar vertebrae is not sufficiently great to make much difference, but it is of great importance in the case of such an injury as a narrow fissured fracture. Even when the bone is a superficial one this may easily be missed if a screen is not used. Unless the antikatode is exactly over the fissure the shadow of the bone as thrown upon a photographic plate may appear to be perfectly normal. With a screen and the power of altering the relative position of the light and the object the fissure is shown at once.

I am not prepared to say that the advantage of the screen over the plate will be permanent. Radiography is so young yet, and improvements in its methods are so numerous and so sudden, that the conditions may be entirely reversed in the course of a month or two. We may in a little while be able to take a series of negatives, one after the other at the same sitting, with rays of different penetrative power and with different times of exposure, and then by combining and studying the results together we may be able to obtain information which shall be more exact and definite than that which we now obtain with the screen. It seems probable from many things that the next great improvement will be in the sensitiveness of our photographic films. At present they allow a very large proportion of the rays, probably 90 per cent, to pass through without producing any effect, and although this can be obviated to a certain extent by placing a screen upon either side of the plate during exposure it is done at the cost of the appearance of the print, the details in which are seriously obscured by the granular effect which is produced even with the finest screen.

Whether an induction coil or a static machine gives the best result in cases of suspected renal calculus depends upon so many considerations that it is impossible to make any definite statement one way or the other. In working with different observers I have been greatly struck with what I can only call the individuality of the apparatus employed and the way in which it responds to a particular method of treatment. A tube, for instance, which has been working well upon a coil seldom gives so good a result at once with an influence machine, and *vice versa*. The cause is in all probability merely a question of adjustment but it makes any attempt at comparison very difficult. Then each man seems to work his apparatus in his own way. This is especially the case with the tubes. One man warms the anode, another heats the cathode, a third connects the tube in some special way. Each man prefers his own method and I believe succeeds best with it.

Local considerations are sometimes of importance. In Cuba, for instance, owing to the moistness of the atmosphere, it is said that the Americans found their influence machines almost unworkable. On the other hand, in the Soudan where the air is intensely dry, Major Battersby, R.A.M.C., preferred a coil, owing to its greater portability, supplying the motor power which was required for his dynamos by an ingenious arrangement of soldiers and bicycles. But if vulcanite can stand the climate, of which I am not sure, it is a question whether some modification of the influence machine, such as Bonetti's, composed of two concentric ebonite cylinders, 50 centimetres high and 50 centimetres in diameter, giving a spark length of 30 centimetres, would not have answered equally well and have been more convenient. The great drawback seems to be that the surface of ebonite plates so soon becomes oxidised, and though it can be renewed by sand papering and re varnishing proceedings of this kind are not always practicable.

The power of dispensing with all forms of batteries and accumulators is a great advantage on the side of the influence machine. Anything can drive an influence machine, it is always ready and it does not get out of order so easily as does a coil. Mr. Wimshurst tells me that he has had one in constant work for 12 years without its failing in any way. There is no risk of destroying the insulation. With plates of sufficient surface it can be made to give a stream of ample volume and the strength of the current, is practically uniform. Moreover, there is good evidence to show that influence machines are much less liable to cause injuries than are induction coils. This is, perhaps, not of so much consequence now that hard tubes and short exposures are employed. The so-called Roentgen ray burns, which are not due to the Roentgen rays at all but to the electric discharge from the surface of the tube and the electrodes, were caused by the prolonged exposure which was necessary when soft

tubes were used. Now such an accident is so rare that although the Roentgen Society sent round a circular to all its members asking for particulars of such cases they received only five replies, and none of these related to cases of recent date. Still the fact for what it is worth tells in favour of the static machine. In another way no doubt it is safer. The current from an influence machine is quite harmless supposing by any chance the patient happens to get into the circuit. I have heard of this happening in the case of a 24-plate Wimshurst machine. One electrode became detached and fell upon the patient's abdomen, which was exposed beneath, without causing him the smallest discomfort. Just as with Tesla's high frequency apparatus it is quite possible, standing upon a glass plate, to light up a tube by holding it in the hand while forming part of the circuit. An experience of this kind would be very unpleasant if a coil were being used.

Surprises, however, as I have mentioned already, are so common and so sudden in radiography that positive statements as to the relative merits of coils and influence machines when difficult cases such as renal calculi are in question can never be of more than temporary value. Within the last few weeks an adaptation of a principle which has, I believe, been known for years and which has been made use of for welding steel—the Wehnelt electrolytic break—has effected what appears to be a complete revolution. It has increased the power of the coil and the steadiness and volume of the stream to such an extent that it is an open question whether the advantage now is not on the other side. In its essentials the construction of the Wehnelt break is exceedingly simple. It merely consists of a platinum and of a lead electrode—this latter of considerable size—immersed in dilute sulphuric acid. It is placed in the primary current with the platinum attached to the positive pole. No condenser is required. The immediate effect is the formation of a brilliant intermittent arc, apparently between the platinum and the acid. The interruption, which appears to be constant for the same strength of acid and the same distance, takes place many hundred times a second. The spark length of the coil is not so great as with a mercury or a platinum break, but the volume is enormously increased and the light obtained is much more brilliant and is perfectly steady. The hardest tubes, those which have a bluish tinge when lighted up and which are unworkable with a platinum or a mercury break, give a magnificent light of immense penetrating power with it. So far it has only been worked with a constant current of high voltage, requiring therefore rather large accumulators, but recently it has been adapted to the alternating supply as well. Whether it will work permanently remains to be seen. It seems to get tired after a time, but generally speaking when this occurs it can be made to start again either by mechanical means or by increasing the strength of the current. There can be little doubt that this is one of the most important advances in practical radiography.

The condition of the patient and the composition of the stone in cases of suspected renal calculus require special consideration. If the patient is thin and anæmic, with poor muscular development, and if the calculus is composed of oxalate of lime positive evidence can usually be obtained. In some instances in which it was doubtful whether the symptoms were due to tuberculous pyelitis or to calculus the point has been definitely settled at once. Tuberculous deposits in the kidney are never sufficiently opaque to throw a definitely limited shadow like that of a calculus. In others in which the symptoms have pointed first to one side and then to the other calculi have been proved to be present in both kidneys, and in others again it has been shown that in addition to the main calculus there were other smaller ones buried in the substance of the kidney which would very probably have been overlooked in an operation. Phosphatic calculi are harder to detect and calculi of uric acid or of urates harder still, in fact, the absorptive capacity of a uric acid calculus is scarcely greater than that of the highly vascular kidney which surrounds it. When the patient is stoutly built, and especially when he is muscular as well as stout, success is much more rare. The tissues corresponding to the larger proportion of hæmoglobin they contain, are more opaque. The calculus is farther from the screen or plate so that its shadow is less well defined, and the distance from light to plate is much greater. On one occasion Mr. Mackenzie Davidson and I in spite of every endeavour failed to get a satisfactory result. The patient was a strongly built and rather stout man who

right iliac region, with a fresh discharge of pus and a fall of temperature to normal, an unmistakable urinary fistula developed. The quantities of urine passed each day through the bladder from July 24th to 31st inclusive were as follows—viz 12 ounces, 10 ounces, 11 ounces, 13 ounces, eight ounces, 12 ounces, 10 ounces, and six ounces, and that passed from the fistula into the dressings was estimated on July 30th and 31st as 10½ ounces and 21½ ounces respectively. On August 1st the large drainage tube which had been used was changed for one of smaller calibre but of equal length. This was immediately followed by a marked diminution in the escape of urine by the fistula and a large increase in that passed by the bladder (on July 31st it was six ounces, on August 1st and subsequent days it was 38 ounces, 44 ounces, 48 ounces, 40 ounces, 42 ounces, and 44 ounces). By August 6th the urinary fistula had closed and a pill of methyl blue, whilst staining the bladder urine, produced no effect on the discharge from the abdominal wound, in striking contrast to what had taken place on July 31st when the same test had been applied. From this date the fistula remained closed, the tube was gradually removed, and on Oct 1st the patient was well and in good condition. There was no abdominal induration and the right kidney could not be distinguished. The patient was seen on May 5th, 1899—nearly a year after the operation. She was quite well and following her usual occupations and the right kidney could not be felt. Though she was somewhat stout there would have been no difficulty in detecting it had it formed a swelling of only moderate proportions.

The point of special interest in this case is the long period—seven weeks—which elapsed between the operation and the development of the urinary fistula. No doubt the abscess was due to slight leakage, but from the remarkable effect produced by the change of tube the inference is natural that the fistulous opening was made larger and practically all the urine from the right kidney directed through it by the pressure produced by the tube upon the ureter below. The rapid closure of the fistula and the immediate large increase in the urine passed through the bladder when that pressure was removed show that two months after the operation no stenosis could have resulted from the inflammatory tissue which had been formed—at least, in that part of the ureter below the wound. Quite possibly, too, the fistulous opening may have been promoted by the gauze packing and the injury to the deposits of lymph which its removal may have caused, but at the time of the operation the union seemed so likely to permit leakage of such a fluid as urine that it was not considered safe to trust it without safeguarding it by a drain, especially as it was impossible to surround it with a peritoneal covering.

A review of the work done in connexion with ureteral wounds cannot fail to notice how nearly all of it has been carried out in America or in foreign countries and how little Britain has contributed to it. The subject is one which has been largely elucidated by the help of experiments and this to some extent no doubt explains why so little attention has been paid to it in this country and why so small a quantity of English literature is devoted to it. It will be seen from the subjoined lists of published cases that there have been 12 cases of complete and five of partial division of a ureter where restoration of the duet has been carried out (uretero-ureteral anastomosis) and seven other cases of complete section in which the upper end of the severed ureter was grafted into the bladder. All these injuries occurred in the course of serious operations and were dealt with during their progress, but in the remaining five cases in Table II bladder implantation was performed as a secondary operation for fistula in some, or as a primary measure for relief of a congenital defect in others. Of all these cases only four died and in every instance the result was quite independent of the ureteral injury. From this it might be imagined that a wound of a ureter is a trivial affair, but inasmuch as injury of these ducts takes place in operations of great severity, in which there is no issue is not improbable even without this of sufficient surface. It is practically certain that the lists are not uniform. Moreover, the influence of the various methods of dealing with injuries to the ureters employed. The so-called of surgical operations the reunion of due to the Roentgen rays uretero-ureteral anastomosis (vide from the surface of the tube—and transplantation of the upper by the prolonged exposure the two methods which aim at a

permanent remedy. Grafting upon the skin or into the vagina should be looked upon as merely temporary expedients and nephrectomy as a final resort only to be adopted under certain serious and exceptional conditions. Of the plans which have at different times been suggested ligation of the ureter deserves some notice, and implantation into the bowel should not be passed over lest it should escape condemnation (*vide* Table III). Lastly, diagnostic ureterotomy, as introduced by Kelly, is so intimately connected with the subject that it may fairly be included within the scope of this article.

UNION OF THE DIVIDED ENDS OR URETERO-URETERAL ANASTOMOSIS

This operation has been carried out in three essentially different ways.

1 *The end-to-end method* consists in the approximation by suture of the transversely or obliquely (Bové's) divided ends, the mucous coat not being pierced. It was employed in the earlier cases of the series. Though the results were apparently satisfactory it seems to have given place to the two following operations which are more easy of performance and probably less likely to be followed by leakage.

2 *The lateral implantation method of Van Hook*—This is easy to understand from a diagram but rather complicated to describe. (a) The out end of the vesical segment is ligatured, (b) a quarter of an inch below the ligature a longitudinal opening is made into the ureter twice its diameter in length, (c) the open end of the upper segment is split longitudinally to prevent cicatricial contraction, (d) two fine sewing needles threaded at opposite ends of a piece of catgut transfixed from without inwards the lower extremity of the upper segment opposite the split ("traction suture"), (e) the needles are then passed through the longitudinal incision in the lower segment and made to transfixed the ureteral wall from within outwards a little distance below, (f) the upper end is now drawn by this suture through the opening in the lower segment and fixed by tying the ends of the traction suture (the anastomosis may be strengthened by a few additional sutures), and (g) finally, the union is enclosed or covered by folds of peritoneum or by a detached omental graft. Blood good has figured a specimen resulting from an experiment showing that after this operation the mucous lining becomes continuous and no constriction of the canal results. It would also appear that no leakage takes place and that the abdomen may be closed without drainage.

3 *In the end in end method* the upper extremity is invaginated into the lower end, which is split longitudinally for half an inch to permit it. The union is then made firm by sutures. This method was introduced by Poggi of Bologna in experiments on dogs, and Mayo Robson, who at the time was not aware of Poggi's work, first employed it in the human subject. Van Hook's method has been used three times and the end in end twice and all have been equally successful.

Of the five cases of partial division all have been treated by direct suture. Of these, two died from the effects of the severe operation they had undergone, but in two of the remaining three leakage took place, a point which rather tells against the end-to-end method for complete division. Should subsequent cases show no better results from direct suture in partial transverse wounds it would be better to complete the section and restore the tube by Van Hook's or the end in end method. There is only one definite piece of evidence of the eventual effect of these operations upon the kidney. In Schopf's case at the end of five weeks the kidney was found to be hydronephrotic and the seat of union embedded in cicatricial tissue. There is, however, sufficient presumptive evidence in favour of the belief that stenosis does not occur frequently from the long periods which have elapsed after the operation in which the patients have been known to be in good health (Kelly's three years, Cushing's five years, Robson's six months, Bové's 11 months, and my own case almost a year).

IMPLANTATION INTO THE BLADDER

Of this operation I have been able to find published records of seven cases performed by abdominal operation

¹ *Annals of Surgery* 1894 vol. xix. p. 70

² For diagrams illustrating Van Hook's method and Bové's oblique end-to-end method vide H. Morris's *Hunterian Lectures* Brit. Med. Jour. April 2nd 1898, p. 873. I am considerably indebted to those lectures and especially for the description of Van Hook's operation.

implantation, pulled the bladder up and attached it on the right side. These proceedings answered the requirements in each case. The experiments which have been performed with this object are of interest.

I should mention (2) has fastened both ends of the ureter into the external wound under considerable tension, a month later the portions had so stretched as to permit of anastomosis, and (3) in another experiment he anastomosed a ureter divided near the bladder with that of the opposite side. Though the experiment was considered a success, when the animal was killed four months after operation yet the ureter had been contracted at the hole which had been bored in the membrane for its passage. This is hardly likely to be of practical utility, for what surgeon would care to tamper with the second ureter in such cases?

2. Wesley Bovee has tried to meet a deficiency of three or more inches by bringing down the kidney and fixing it at the level of the iliac crest. From two experiments on dogs he concludes that the operation is a practical one.

3. Budyger has proposed to implant both ends on the abdominal wall and fashion a connecting channel from skin between them. It hardly needs the observation of Emmet that "either the distal end atrophies and becomes useless or it is found that no tissue can be utilized to connect the two can serve as a carrier of urine," to make us look askance at such a plan.

TABLE III.—CASES OF IMPLANTATION OF THE URETER INTO THE BOWEL.

Date.	Name.	Method, &c.	Result.	Why performed.
1892 (2)	Simon: Surgical Treatment of Children's Diseases, Holmes, p. 171.	Loop of thread, passed in an ingenious manner made to liberate through rectum. Communication resulted. Three escaped by the skin although the ureter remained patent.	Death one year after operation. Suffering pyelitis on both sides.	For ectropion of the bladder.
1893.	W. Smith, St. Bartholomew's Hospital Reports, 1893, vol. xv, p. 29.	Each ureter inserted into the back of the coccyx on the corresponding side. Operation on the second ureter 14 months after operation on the first. Fatal in 24 hours.	Necropsy.—Left kidney hydro-nephrotic from stenosis—a probe passed along the ureter would not enter the bowel. Right kidney at junction with bowel. Kidney showed chronic changes.	For ectropion of the bladder.
—	Kuster: Annals of Surgery, 1894, vol. xx, p. 193.	Both ureters into the rectum.	Death purulent peritonitis sutures did not hold. renal infection.	Cystectomy for cancer.
1892.	Clapart: Annals of Surgery, 1894, vol. xx, p. 193.	Ureter divided junction made with posterior surface of the colon on the left side.	Successful death in posterior peritoneal space, 12 months after operation.	For uretero-vaginal fistula after operation for ectropion of the bladder.
November 1892.	Clapart: Annals of Surgery, 1894, vol. xx, p. 193.	The first ureter was successfully implanted the second ureter was implanted three months later.	Death occurred the same day. There was no necropsy. The patient became comatose, there was suppression of urine, the ureters motions ceasing.	For tuberculous cystitis and following operation.

5. Lastly, Van Hook suggested the creation of a diverticulum from the bladder which should be placed in the abdominal wall and be long enough to meet the upper end of the ureter. Vital operation was of this nature.

Practical Points and the Choice of Operation.

There are some practical points in connection with these operations which deserve special mention. 1. Van Hook pointed out the great elasticity of the ureters which permitted them to be stretched or dilated to a considerable extent. There is no need to emphasize the importance of this fact. 2. Oblique section of a ureter so as to give a larger sectional area and diminish the liability to stenosis may be adopted under many different conditions. In implantation the grating end is split for the same reason. 3. Lastly, in bladder implantation the extremity of the vesical portion of the ureter should be tied, as leakage of urine from the bladder has been known to take place from it.

As operations uretero-wetral anastomosis and implantsation into the bladder have each their proper sphere. Kelly puts the matter concisely in this way: "When the ureter is cut far enough back from the bladder to permit an anastomosis of the upper into the lower end the distance between

1. Ibid., vol. xxi, p. 379.
2. Ibid., vol. xxi, p. 312.
3. Kuster's paper, Ibid., 1893, vol. xx, p. 257.
4. Ibid., vol. xxi, p. 73.
5. Kuster's paper, Ibid., 1893, vol. xx, p. 257.

Implantation into the bowel.—Great hopes were entertained at one time that the difficulties of treating divided ureters would be settled in this way. Many names are associated with the experimental surgery of implantation of the ureters into intestine, but it must be admitted that the results have been disastrous. As evidence of this it will be sufficient to quote the experience of Harvey Reed. Of six bilateral implantations in animals all died, the causes of death being acute peritonitis, nephritis with some obstruction, and hydro-nephrosis. Of three unilateral operations one told nothing as the post-mortem examination was spoiled, one had nephritis and hydro-nephrosis when killed, and one was satisfactory when killed on the twenty-fifth day. 10. Nor are the results of the operation in the human being more satisfactory, as will be seen by a study of the accompanying table (Table III) of all the published cases in which this method has been adopted for any cause whatever. The frequency with which failure resulted from septic infection of the kidney both in the experiments and in the cases is only what our present knowledge would lead us to expect, but in addition to this, constriction was often found to result at the seat of the implantation. An improved operative technique might have overcome the latter difficulty, but the inability to avoid kidney infection has prevented grafting into the

one inch) or that a certain portion has been rendered useless for operative purposes from being embedded in cicatricial tissue. Though the ureter is capable of considerable stretching and Robson found no difficulty in invaginating the upper into the lower end in his case because the tube was so dilated and elongated, yet there have been occasions, chiefly in cases of implantation into the bladder, in which the strain has made it necessary to adopt measures to avoid it. And the

possibility of having to meet a serious deficiency in length has led to a variety of experiments to test the feasibility of the ideas suggested for overcoming it. The following plans have been tried in the human being: (1) Kelly cut away the bladder from its attachment in front and at the sides so that it lay loose on the pelvic floor, (2) Baldy fixed the bladder by suture to the pelvic wall, close to the stump of the ovarian artery, and (3) Witzel, in his extra peritoneal

TABLE II—CASES OF IMPLANTATION OF THE URETER INTO THE BLADDER

Abdominal Operations

Date.	Name	Method.	Result.	Drainage, &c.	Condition for which the initial operation was undertaken.
1893 (published)	Novaro, quoted by Fenner: <i>Annals of Surgery</i> , 1894, vol. xx., p. 257.	Paoli and Busachi's. Distal end of ureter split and united by suture to incision in the bladder.	R.	Gauze drain, leakage of urine for several days.	Uretero-vaginal fistula following hysterectomy for carcinoma.
1894	H. A. Kelly: <i>Kelly's Operative Gynecology</i> , vol. 1, p. 461, and Johns Hopkins Hospital Bulletin February 1895.	End of ureter split, drawn through small incision in the bladder (4 mm) by forceps passed through the urethra, across the bladder and through the incision. Six interrupted sutures fastened the muscular tissue of the bladder to the outer coats of the ureter. The bladder was cut away from its attachments in the front and sides to enable approximation to be made.	R.	Gauze drain, no leakage.	Uretero-vaginal fistula resulting from vaginal hysterectomy for carcinoma.
1894 (published)	Krug: <i>American Gynecological and Obstetrical Journal</i> , November 1894. Abstract, <i>Annals of Surgery</i> , 1895, vol. xxi., p. 224.	Distal end of the ureter split and inserted by traction sutures as in Van Hook's method of uretero-ureterostomy, careful closure of the bladder.	R.	Abdominal wound closed; catheter in bladder four days. Cystoscope has since proved patency of implanted ureter.	Intra-ligamentous uterine fibroid hysterectomy.
1894 (published)	C. B. Penrose: <i>Annals of Surgery</i> 1894 vol. xix., p. 686.	Distal end implanted through an incision half an inch long by means of Van Hook's traction sutures (two). Peritoneum covering ureter was drawn down and sutured to the peritoneum over the bladder.	R.	No drainage catheter in bladder three days.	Carcinoma uteri involving the left ureter; one inch excised; abdominal hysterectomy.
1896 (published)	J. M. Baldy: <i>American Journal of Obstetrics</i> , March, 1896. Abstract, <i>Annals of Surgery</i> 1896 vol. xxiv., p. 767.	Ureter implanted by two Van Hook traction sutures. The bladder wound was closed in three layers by continuous catgut sutures which were also made to fix the ureter. There was considerable tension on the ureter so the bladder was fixed by suture to the pelvic wall close to the stump of the ovarian artery.	R.	Glass drainage tube; removed on third day. Catheter every four hours.	Right ureter was torn across in enucleation of an intra-ligamentary cyst. Tumour and uterus were removed.
1896 (published)	Witzel: <i>Centralblatt für Gynäkologie</i> , 1896, No. 11. Kelly's <i>Operative Gynecology</i> , vol. 1, p. 464.	Ureter traced from the pelvic brim and divided at the middle of the broad ligament. The lower end was closed. The upper end was drawn beneath the peritoneum above the innominate line by long forceps started upwards under the peritoneum to the right of the bladder. The peritoneal incision was closed. The remaining proceedings were extra peritoneal. The bladder was pulled up and attached on the right side until the ureter cut obliquely, could be implanted on the same principle as in Witzel's method of gastrotomy—by oblique channel made by uniting folds of bladder walls on each side over the ureter.	R.	Bladder drained.	Uretero-vaginal fistula for which vaginal operation had failed.
	Anna Fullerton, quoted by Kelly: <i>Operative Gynecology</i> , vol. 1, p. 463.	Double ureter divided accidentally. Vesical ends ligated. Both orifices were introduced into the bladder by a common opening.	R.	—	Double pyosalpinx.

Sacral, Vaginal, and Vesical Operations

1894 (May 2nd)	Westermarck: <i>Annals of Surgery</i> , 1895, vol. xxiii., p. 333.	Sacral incision. Out end of ureter was sutured into the partially closed defect in the bladder. A double row of sutures were so arranged that the sides of the ureter were united with the sides of the bladder.	R.	Well, Feb. 9th, 1895.	Carcinoma uteri in which the bladder and left ureter were involved. Removal of affected parts.
—	Abbe: <i>Annals of Surgery</i> , 1894, vol. xx., p. 183.	Sacral incision. Ureter inserted into the vesical pouch.	R.	No leakage. Patient believed to be cured.	Supposed abscess; really foul vesical pouch ureter torn.
—	Davenport, quoted by Fenner: <i>Annals of Surgery</i> , 1894, vol. xx., p. 287.	Vaginal operation. Ureter displaced and the orifice implanted into the bladder.	R.	—	Ureter opening close to the external orifice of the urethra lying in vesico-vaginal septum and causing incontinence.
1892 (published)	Baumin: <i>Annals of Surgery</i> , 1894, vol. xx., p. 286 (Fenner's paper).	Bladder opened (suprapubic), misplaced ureter divided, distal end ligated, proximal end connected with bladder operation extra peritoneal.	R.	This operation was chosen because the patient was a virgin.	Accessory ureter opening into urethra and causing incontinence.
1896	E. Kuster Abstract, <i>Annals of Surgery</i> , 1897, vol. xxv., p. 663. Verhandlungen der Deutschen Gesellschaft für Chirurgie, Twenty-fifth Congress, 1896.	A man, aged 32 years. Suprapubic section, evidently cystotomy. Removal of a large portion of bladder-wall and several centimetres of ureter. Ureter sutured in the upper angle of the bladder defect which was then sutured throughout. The bladder was left open for secondary suture.	R.	—	Growth of bladder.

It has not been thought worth while to separate the cases into groups, but in two cases the operation was performed for a congenital condition and not for injury immediate or remote.

colon or other portion of the bowel attaining the position of a sound surgical measure. With the satisfactory results which can now be obtained by uretero-ureteral anastomosis and uretero-cystotomy it is safe to conclude that implantation into the bowel has been relegated to the limbo of oblivion.

Ligation of the ureter.—Nor is it likely that ligation of the ureter will ever have a practical value in ureteral wounds. Guyon suggested it as a substitute for nephrectomy in these cases to save an undue prolongation of the operation,¹¹ for as soon as the distension pressure in the pelvis and ureter equals the blood pressure the secretion of urine ceases and experiments tend to show that atrophy of the kidney results. For this to occur, however, the urine must be aseptic, or a pyonephrosis will develop, and, needless to say, the presence of a second kidney is essential. One fact, however, is interesting. By ligation of the ureter the function of the kidney may be kept in abeyance for a period without obvious harm. Thus, Robinson¹² quotes the case of a woman in whom the ureter of one side was ligatured for six weeks. At the end of that time the ligature was removed and the kidney resumed its function as before. And whoever has watched a ureteral fistula develop on the separation of the ligatures in vaginal hysterectomy has seen the same fact accidentally demonstrated. Simple as the proceeding is, it does not appear to be at all free from the risk of miscarriage, and this uncertainty as to risk and eventual result outweighs any advantage which the ease of its performance might give it in the rare cases in which it might be made use of.

DIAGNOSTIC URETEROTOMY

The subject of ureteral injuries should not be dismissed without reference to a plan known as "diagnostic ureterotomy" which has been introduced by Dr Howard Kelly whose labours have done so much to advance this department of surgery. In four operations in which he had reason to fear that he had included a ureter in a mass of ligatured tissue he exposed the ureter at the pelvic brim, made a longitudinal incision into it, and passed a ureteral sound down towards the bladder. In two cases he found the ureter free, but in the other two the sound stopped short at the ligated area. The ligatures were removed and the sound passed on into the bladder. The incision was closed with mattress sutures and though in three at least of the cases a gauze drain was used, no leakage took place and no trouble resulted either from the temporary ligation of the ureter or from the operation.¹³ As Mr Henry Morris points out in his interesting Hunterian Lectures the general tendency of advance in renal surgery is in the direction of conservatism. The first nephrectomy was performed by Simon 30 years ago for ureteral fistula and injured ureters were at first treated in the same way. With the gradual growth of ureteral surgery nephrectomy has fallen into the background and in the case of wounds will be very rarely justifiable. And diagnostic ureterotomy, inasmuch as it aims at the prevention of wounds or the avoidance of the suppression of the functional activity of one kidney, is a step in the same direction.

Leeds.

INTESTINAL OBSTRUCTION¹

By R O ELSWORTH, M.B. EDIN., F.R.S. ENG.,

SURGEON TO THE SWANSEA HOSPITAL.

WHEN I promised to read a paper before the Swansea Medical Society it was with many misgivings, and in appearing before you to night it is not with the idea of saying anything new but rather with a view of inviting discussion and eliciting your opinions. For it is written that "in the multitude of counsellors there is safety," even though it may be the counsellors only who are safe.

The subject of abdominal surgery is one which has engrossed the minds of medical men during the last few years more than any other subject in medicine, excepting

perhaps that of bacteriology. Within the cavity of the abdomen are contained many and most important organs, not the least of which is the alimentary canal, the functions of which are associated with much of the joy and misery of this life. But it is not so much with the functions of the bowel that we are concerned to night as with stoppage of the vital though turbid stream within it. The subject of obstruction is not the least important of those which fall within the domain of abdominal surgery, and though much has been written and said concerning it I hope you will bear with me while I endeavour to lay before you certain facts which may in some slight way serve to increase your interest in the matter.

The causes of obstruction are so varied and their mode of action so complicated that it is impossible in a short paper like this to do more than mention some of them. They may be arranged under three heads: (1) those in the bowel, (2) those in the bowel wall, and (3) those outside the bowel wall. Those in the bowel are (a) concretions, intestinal or biliary, (b) fecal accumulations, (c) foreign bodies, and (d) tumours. Those in the bowel wall are (a) cicatricial stricture, (b) stricture due to tumours, simple or malignant, (c) twists, and (d) intussusception. Those outside the bowel wall are (a) bands inflammatory or other, adhesions whether binding the gut to other organs or surrounding it, and kinking, (b) stenosis produced by holes in the mesentery or omentum, internal hernia, and (c) occlusion by fecal remains, as Meckel's diverticulum. Lastly, there is an important group which is quite distinct from these—viz, hernia of omentum, strangulated ovarian cyst, orchitis in an undescended testicle, crushed testicle, inflamed hydrocele, phlegmon of the upper part of the abdominal wall, perforating gastric ulcer, paralysis of the bowel, appendicitis, and peritonitis. With the subject of external hernia I do not propose to deal.

It has been stated that the cause of obstruction may be in three positions as regards the wall of the bowel. It may also be in three positions as regards the length of the gut. It may be low down in the second half of the large intestine, it may be high up in the small intestine—jejunum, or it may be intermediate in position, say in the lower part of the ileum. It may, again, be acute or chronic.

It is often complained that too much is made of the pathological aspect and mechanism of conditions which are met with by the busy practitioner and not enough of the signs and symptoms by which these conditions may be recognised and treated. Now it is not my intention to burden you with an account of conditions which can only be made out in the post-mortem room, but rather to dwell upon the signs and symptoms by which obstruction may be recognised. For upon the recognition—may, upon the early recognition—of the case depends the treatment, and the safety of the patient.

Let us look for a moment at the classical symptoms of obstruction with which you are all familiar. We find that they consist of pain, of fecal vomiting, of stoppage of the bowels both to wind and more palpable material, sometimes preceded by a profuse diarrhoea, of swelling of the abdomen or meteorism consequent upon which there is more or less difficulty of breathing, alteration of pulse, furred tongue, scanty urine, and general depression. I think it may be taken as an axiom that all patients who have these symptoms have obstruction, but all who have obstruction have not these symptoms and it is to draw your attention to these cases that I have ventured to address you to-night. When we consider the classical symptoms we are struck with the fact that in many cases of obstruction there is not the condition of obstruction only to deal with, but that there are really two conditions—viz, obstruction plus strangulation—and, further, that strangulation is by far the most urgent condition. Let us consider the classic symptoms individually.

Pain is one of the earliest symptoms to appear and it is one which it is well worth while to study carefully. Its origin is twofold. It is due (1) to the direct injury caused to the tissues by the constricting agent, and (2) to the violent, irregular, and futile peristaltic action of the bowel. It is colicky and paroxysmal in character and though it is produced at varying points in the abdomen, yet there is a singular uniformity as to the position in which it is felt. It is felt in the region of the umbilicus. It is relieved by pressure and is generally unassociated with tenderness. It varies in amount at different times and one feature of special importance is that it

¹ An address delivered before the Swansea Medical Society on Jan. 24th 1899.

[MAY 27, 1899]

It will be well to mention two other forms of obstruction at this place—viz, volvulus and intussusception. In always acute, it presents the characters of the first type with rapid and great distension of the abdomen soon followed by great tenderness commencing in the left iliac region and spreading thence over the abdomen due to early peritonitis. Intussusception is never a form of complete obstruction and consequently the symptoms it presents do not assume the characters of any type—namely, the position of the obstruction varies at different times. But there are two or three points which it is well to bear in mind concerning it that may be of great assistance in preventing error. These are, first, that the tumour may not be palpable except during the paroxysms of pain, secondly, that it can never be felt in the hypochondriac regions, thirdly, that there is usually well marked tenesmus, and fourthly, that there is the occurrence of bloody mucus in the motions. I need not dwell on these matters. Lastly, there is a set of cases which require to be specially mentioned and which are of great importance to the point of view of treatment. I refer to cases of spurious strangulation, false strangulation, and pseudo-strangulation. In this condition the patient presents all the signs and symptoms of acute strangulation and obstruction without there being any interference with the lumen of the bowel. It is due to various causes, amongst which may be mentioned oedema in an undescended testicle, inflamed hydrocele, phlegmon of the upper part of the abdominal wall, perforating gastric ulcer, perforating appendicitis, peritonitis, fibroid of the bowel, and strangulated ovarian cyst or fibroid. In this class of cases the symptoms are always acute and the type which any case assumes will depend on the time for which the condition lasts. At first the case will present the characters of the third type and later those of the second type, but probably only the first type when the condition is peritonitis and paralysis of the bowel. If the patient dies rapidly the case may retain the characters of the third type to the end.

DIAGNOSIS

The question of diagnosis is very perplexing and I suppose there are few, even of the most experienced, who have not at times felt wiser after, or at least towards the close of, a case of obstruction than they did at the beginning. For this reason I think that we may, I hope not unprofitably, devote a little time to the consideration of this subject. For purposes of diagnosis cases of intestinal obstruction may be divided into the following: 1 Cases of acute obstruction 2 Cases of chronic obstruction 3 Cases of chronic obstruction in which symptoms of acute obstruction supervene

1 *Acute obstruction*—This may be due to a lesion of either the small or the large intestine. In the small intestine it may be due to strangulation by bands or through apertures, by kinking, by foreign bodies, and by one variety of intussusception. In the large bowel it may be due to volvulus or intussusception. In the first place it is important that we should make a thorough examination of the case. All the usual regions where hernia occur should be carefully explored and inspected, and the rectum should be examined. The nature of the pain should be carefully investigated as to constancy or not and the condition of the patient between the paroxysms of pain. The vomit and other evacuations should be inspected if possible.

Let us assume a case where the obstruction is complete. The following points will be of value in assisting to a conclusion. The pain will be constant with paroxysms during which the vomiting will most probably be marked. The vomit may be fecal or not fecal—that does not matter. The vomit is in a condition of prostration, with a pinched face, cold sweat, pale or livid skin, a rapid, small, and feeble pulse, and a tongue becoming dry and brown. He passes little urine which is high-coloured, and he is anxious about his condition, and mentally he is in a state of horrible anxiety. On looking at the abdomen we may get valuable information. If the abdomen be distended, bulging both forwards and laterally, and if there is tenderness in the left iliac region or if there is tenderness over the greater part of the abdomen but worse in the left iliac region and tympanitic on percussion then the case is most probably one of volvulus of the sigmoid. If the abdomen is tympanitic with little or no tenderness, with bulging forwards but not laterally, then

the case is most probably one of obstruction low down in the small intestine. Again, if the abdomen is tympanitic and unaltered in shape—i.e., with no distension or at least distension of the stomach as sometimes occurs before vomiting—then the obstruction is probably high up in the small intestine. In intussusception the obstruction is never complete and the contour of the abdomen presents no guiding characteristic, but during the paroxysms of pain the hand may discover a tumour, there are tenesmus and the evacuation of bloody mucous discharge. The case, too, is seldom very acute.

2 *Chronic obstruction*—This may be due to stricture of the small or the large intestine, to fecal accumulation, or to chronic intussusception. The patient complains of digestive troubles with attacks of colicky pain in the abdomen, the bowels do not act satisfactorily, and he probably finds that the indigestion, the pain, and the constipation occur together. He is also much troubled with flatulence. The tongue is probably furred, the breath is offensive, and little flatus is passed. On examining the abdomen if we find a tumour in the line of the large bowel which pits on pressure and probably is somewhat tender it is fecal accumulation. If the tumour hardens or becomes more distinct under pressure then it is intussusception. If the abdomen is distended, bulging in the flanks as well as forwards—i.e., globular in shape—with or without coils of intestine showing on the surface, tympanitic, and with no tumour to be made out, then the case is one of stricture of the large intestine low down. If the left flank is flat and the right bulging the stricture is above the descending colon. If both flanks are flat and the bulging is chiefly forwards then the stricture is low down in the small intestine. If the abdomen is unaltered in shape or bulging only in the upper part then the obstruction is high up in the small intestine.

3 *Chronic obstruction in which acute symptoms supervene*—It will be unnecessary to enter into this class of cases after what has been already said. The cases present the symptoms of acute obstruction like those mentioned, but inasmuch as there may not be strangulation the constitutional depression may be much less marked.

TREATMENT

The treatment may be divided into the medical and the surgical. The medical treatment comprises the administration of drugs, the arrangement of the diet, and attention to the creature comforts generally and the use of enemata. The use of enemata is of great value both as a means of treatment and as an aid to diagnosis and should be employed as early as possible. As regards drugs, the number which are of any use in these cases is very small and their value is very limited. No drug has yet been discovered which is capable of undoing a twist of the gut, loosening a knot, or reducing a hernia, but there is one drug or group of drugs the use of which may be, and is likely to be, fraught with disaster. I refer to aperients. Unfortunately they are usually administered by the friends of the patient before the case is seen by a medical man. There is ample evidence to prove that this class of remedies has converted chronic cases into acute and has turned the balance against those of a less urgent character. It would appear that the use of aperients is, if anything, worse than the unguarded use of opium. This drug is of special value, indeed, its great value is one of the chief drawbacks to its use. On this account it should not be administered until the diagnosis has been made. This having been accomplished, and it being borne in mind that it is but a palliative measure, it will be found that the vomiting, the pain, the subnormal temperature, the pulse, the scanty urine, and the collapse, are all improved for the very benefits it confers. But in many cases it is a broken reed to lean upon, likely to prove entirely delusive and the sad awakening comes all too late. I believe that the administration of opium is calculated to improve a patient's chance of bearing the shock of operation. Finally the medical treatment of a case of obstruction may be briefly summarised by saying that it usually consists of waiting till it is too late.

In the present state of our knowledge I fear that any hope of recovery which cases of obstruction may have must depend upon surgery, not upon medicine. And here we come face to face with the question of operation, which is always a serious one both for the medical adviser and the patient. The operative treatment of intestinal obstruction has been

The quantity of ascitic fluid and an enormous multilocular cyst umbilicus and the use of a hernia and these were excised after separating the adherent omentum the tumour was found to be of the left ovary and to be buried in the broad ligament an extensive evacuation was necessary for its removal but very little blood was lost. The liver was seen to be cirrhotic and the spleen and the omental vessels to be enlarged, so the omentum was sutured across the anterior abdominal wall. The abdomen was closed without drainage. For the first week after the operation the patient was exceptionally well and looked as if there was no doubt as to her recovery. Then she had an attack of diarrhoea with some vomiting, she became lethargic, and she refused her food. On March 27th it was noticed that her pulse had become markedly intermittent. She steadily went downhill and died on March 29th, on the eleventh day after the operation. A post-mortem examination limited to the abdomen corroborated the opinion formed at the operation. There was some free fluid in the abdomen. Both kidneys were in an advanced cirrhotic condition, not smaller than normal, but markedly granular on the surface with adherent capsules. There were no surgical complications. I think, judging by the symptoms and the result of the limited post-mortem examination, that death was due directly to the kidney lesion. It is more rare than I thought to see uncomplicated cases of liver cirrhosis and ascites. Valvular heart lesions, thoracic aneurysm, albuminuria, and glycosuria, are the most frequent complications which I have met with and each would seem to contra-indicate operation because but seldom can the latter two be temporary. Of my two previously recorded cases one was temporary in curing the ascites, the other was not. The clinical diagnosis of liver cirrhosis was not in the latter case corroborated by surgical examination of the liver, and Dr William Brewster suggested at a meeting of the Harveian Society of London on April 6th 1899, that my case might be similar to one under his care. In this case the operation failed to cure an obstinate ascites. In his case several months after the operation in the case the post-mortem examination showed a universally adherent pericardium shrunken by a layer of calcareous salts which must have precluded the contraction of the ventricles. The liver was not cirrhotic. I have now operated on four cases. Two were uncomplicated and were regarded as suitable cases for operation and both of them were cured. In one the diagnosis was doubtful, and in another the complications were such as to preclude recovery. The conclusions which I have come to are as follows: 1. Ascites due to liver cirrhosis can be cured by the establishment of an efficient anastomotic circulation. 2. Adhesions peritonitis produces adhesions between the abdominal contents and its parietes in which new blood vessels form. If there is any demand for the new blood vessels they remain permanently. 3. The operation described in the paper by Drummond and myself is the safest and longer advisable to treat the ascites due to cirrhosis by repeated tappings if the patient is otherwise sound and in fair general condition. After one or two tappings have failed operation offers the best chance of prolonged and useful life.

Newcastle-on-Tyne.

Brit. Med. Jour. Sept 19th, 1896.

BRISTOL JUBILEE CONVALESCENT HOME—At a recent meeting of the governors of this institution it was stated that when all the expenses of the home had been paid £55,000 will remain for endowment purposes. Mr E. F. Willis has since promised to subscribe £5000 provided another £15,000 be raised within three months. This would be sufficient to give the £65,000 required to endow the 65 beds allotted to the infirmary, hospital and other medical charities and would leave a sum the income from which would be applied to reducing the charges made for the 15 beds allotted to other patients. Mr J. S. Fry has promised to provide the last £2000 of the £15,000 required and Mr Vaughan has given £1000 for the endowment of another free bed.

Good condition she was in, I could not refuse to undertake the operation. The operation was performed on Oct 5th, 1897 by a method of my own without opening the peritoneum. The only peculiarity observed was that the sub-peritoneal vessels were large and bled freely. She recovered in an hour from the immediate effects of the operation but towards evening became very restless and complained of prickling pains and numbness in her arms and legs. Next morning after a restless night I found her distinctly jaundiced and comatose. The abdomen was very tender when touched. The jaundice and restlessness increased and on the second day after the operation she became comatose and died at night, deeply jaundiced. *Post-mortem evidence.*—At the necropsy Mr W. G. Richardson removed the whole of the abdominal viscera and the parietes, excepting the skin, in mass. He then injected the whole from the trunk of the portal vein. I showed the specimen at a meeting of the North-amberland and Durham Medical Society on Nov 11th, 1897, and in demonstrating it I said: "The liver the spleen and the intestines are seen to be attached to the parietes chiefly by numerous bands and large adhesions." (Many of these seemed to contain little except a blood vessel and in several of them such vessel was four inches in length.) The omentum also is firmly adherent over the anterior abdominal wall by strong bands. In all of these adhesions innumerable injected vessels are really seen passing from the omentum and viscera to the parietes. Many of them are fully the size of a normal radial artery. The sub-peritoneal plexus of vessels forms a dense large network. This specimen establishes our belief that an efficient anastomotic circulation can be brought about by operation. There can also be no doubt that this patient was cured of ascites and that useful life was prolonged to her for two years by the operation. A further examination of the specimen shows the liver to be much atrophied and degenerated. The spleen is at least four times its normal size. It is quite evident that the observed portal cirrhosis was nothing to do with the splenic enlargement—in this case at all events—for the new anastomotic circulation is clearly more than sufficient to compensate for any diminution in size of the portal vein."

Typical cirrhotic with much fatty degeneration of the liver. So called new bile ducts present in numbers, liver cells showing extreme fatty degeneration in all zones and normal cells few and situated in a central portion of lobule."

In another case I have performed the operation for the cure of ascites and though the case is of no value in forming an estimate of the worth of the method I think it is right to report it, as the introduction of a new operation should be expected to offer the whole of his experience concerning it. The patient, a woman aged 57 years, was sent to me by Dr Welch of Felton when she was very ill. She was an exceedingly stout woman and had enormous distension of the abdomen. 18 months previously she noticed her legs to be swollen for the first time. One year previously though always very stout, she found herself getting stouter and this was most noted in the abdomen. Up to two months ago she was able to attend to her business and felt fairly well, then the swelling of her abdomen and legs which had been steadily increasing incapacitated her and for the last three weeks she had been confined to her bed. Her mother died from "consumption" and her father from pneumonia, all her fatherly had had delicate chests and her only sister had died from "consumption." Eight years previously the patient had pneumonia and bronchitis, to which she was subject, but had a rupture at the navel. When I saw her on March 5th, 1897, her legs and abdomen were enormously swollen and beyond ascertainment that there was a quantity of free fluid in her abdomen and some albumin in her urine. I learned nothing from careful physical examination. On March 6th I tapped her and removed five and a half gallons of ordinary ascitic fluid. This made no perceptible difference in the size of the swell- ing but I thought that I could not feel that the bulk of the enlargement was due to a round elastic tumour. On March 18th I opened her abdomen and found in addition to a

time of the operation, otherwise the patient may die poisoned by his own excrement, and (8) that it is probably safer to be content with colotomy or enterotomy where the bowel is seriously damaged than to attempt an operation for mastomosis

Swansea.

CURE OF ASCITES DUE TO LIVER CIRRHOSIS BY OPERATION

NOTES OF A SECOND SUCCESSFUL CASE AND OF A POST-MORTEM EXAMINATION

By RUTHERFORD MORISON, F.R.O.S. EDIN.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

DR. DRUMMOND and I have already published a paper¹ on the cure of ascites due to liver cirrhosis by a surgical operation. The design of the operation, as we then pointed out, was to relieve the obstructed portal circulation by the establishment of an efficient anastomotic one. I propose to offer now further evidence, both of a clinical and post-mortem character, that this can be successfully accomplished.

A man, aged 42 years, was sent to me in January, 1897, by Mr G Longbotham of Middlesbrough, complaining of swelling of his bowels. It appeared that eight weeks previously he had felt unfit to attend to his business from weakness, having an uncomfortable puffed up feeling after meals and being somewhat swollen. Since the beginning of the year the swelling had increased very rapidly. Except for a history of three attacks of pneumonia, always in the left lung, there was nothing to note in his previous health and his family history was excellent. With regard to alcohol he said that he never took more than a pint of beer to his dinner and supper, and very occasionally a glass of whisky, and that he had always been temperate. This statement was corroborated by his wife and by Mr Longbotham. His arms, his legs, and his chest had got much thinner since his illness commenced. His organs, with the exceptions to be presently noted, appeared to be sound. His abdomen was much swollen and it felt tense. All the signs of a large collection of free fluid were present. No liver dulness could be distinguished. His spleen was so much enlarged as to fill the left ilio-costal and lumbar spaces and to bulge forward the left flank. A distinct notch was felt in the tumour, showing it to be spleen, in a line drawn from the umbilicus to the ninth left costal cartilage and midway between the two. Never having seen so large a spleen before in liver cirrhosis, before deciding to operate I asked Dr Drummond to see the patient. He concluded that the ascites and enlarged spleen were due to liver cirrhosis and advised operation.

The operation was performed on Jan 12th, 1897, under chloroform. The abdomen was opened midway between the umbilicus and ensiform cartilage sufficiently to admit my index finger for exploratory purposes. The characteristic hard, hobnail surface which was felt on reaching the liver left no further doubt as to the diagnosis and the parietal incision was extended from the ensiform cartilage to the umbilicus. I then introduced my hand into the abdomen and projected my finger against the anterior parietes three inches above the pubes and made an opening sufficiently large there to admit a glass drain into the recto-vesical pouch. About two gallons of fluid escaped from the upper opening and through the tube. Through the upper opening a perfect view of the liver and spleen was obtained. The liver presented the typical appearance of the ordinary form of alcoholic cirrhosis and although diminished in size was not so much contracted as we expected it might be from the diminished liver dulness. The spleen was enlarged to at least six times its normal size. After emptying the peritoneal cavity and drying it with sponges, the anterior surface of the liver, the outer surface of the spleen, the exposed coils of intestine, and the parietal peritoneum were all firmly sponged and the omentum was attached by sutures widely to the parietal peritoneum lining the anterior abdominal wall as described in the paper to which I have referred above. The whole of the upper wound was closed by deep and superficial sutures and the glass drainage tube was left projecting and firmly gripped

below. Wide, long strips of strapping were applied firmly over the dressing from the epigastrium down to the drainage-tube. The nurse who was left in charge was directed to keep the dressing dry by frequently emptying the tube with a pump. The operation was completed at 12.45 p.m. The after progress of the case was as follows. Fluid was drawn off at 2.15 p.m., at 2.45 p.m., at 3.15 p.m., at 3.45 p.m., at 4 p.m., at 4.30 p.m., at 5.15 p.m., at 6.10 p.m., at 7 p.m., at 7.40 p.m., at 9.15 p.m., at 10.15 p.m., and at 12 midnight. The total amount of fluid drawn off since the operation was 8 oz 4 dr. On Jan 13th fluid was drawn off at 2.30 a.m., at 4.30 a.m., at 6 a.m., at 7.40 a.m., at 9.15 a.m., at 10.40 a.m., at 12.35 p.m., and at 2.45 p.m. The total drawn off during the 24 hours was 6 oz 6 dr. On the 15th fluid was drawn off at 6.15 a.m., at 9 a.m., at 1.30 p.m., at 3 p.m., at 10 p.m., and at 12 midnight, and on the 16th at 1 a.m., 3 a.m., and at 6.30 a.m. The total for the 24 hours was 4 oz. The wound was dressed for the first time on the 18th, when the glass tube was removed and a small indiarubber one was inserted. On this day and on the 19th and 20th the dressing was frequently changed to keep the wound dry. The wound was dry all the night of the 21st, and on the 26th the indiarubber tube was taken out. The patient went home on the 28th with the wound healed except where the drainage tube had been.

The general recovery of the patient requires no note. From the surgical point of view it was straightforward. It was, however, evident during the last few days of his stay in Newcastle that he was much depressed mentally and after his return home the depression increased and for three weeks he was alternately depressed and excited. This feature seems to me to be deserving of more attention than would have been given to the same in an ordinary case, for it may possibly be one of the special risks of this operation. Dr Drummond has brought before the Northumberland and Durham Medical Society at various times cases of liver cirrhosis complicated by peculiar nervous symptoms, and in one patient who died he was unable to find any change in the nervous system to account for the symptoms. In that case the liver was in an advanced stage of cirrhosis, there was no ascites, and there was a very large vein of Sappey connecting the portal with the systemic circulation. The explanation given by Dr Drummond of the attacks—viz., that they were due to intestinal products finding their way directly into the systemic circulation without any liver influence being brought to bear on them—is in accordance with the fact that this patient was on several occasions rescued from an apparently hopeless coma by the administration of a brisk purgative and also with the results of experiments on the liver functions. 10 months after the operation my patient was shown at a meeting of the Northumberland and Durham Medical Society. He appeared then to be in excellent health and said that he felt perfectly well. His spleen, though considerably less, was large enough to be easily felt. There was no sign of fluid in the abdomen. I next heard definitely of him in January, 1899. A well known insurance office wrote asking me to report on the nature of the operation performed two years previously. He had been passed by the medical adviser of the company as a first-class life, but before completing the insurance I was consulted.

The only difference between this operation and those previously recorded by me was in the position of the parietal incision. The main opening in this case was made above the umbilicus and was only large enough to admit a drainage-tube below that point. The importance of avoiding the chance of a ventral hernia will be seen later.

The patient in the first successful case, a woman attended the Medical Section at the annual meeting of the British Medical Association at Carlisle eight months after the operation and was then apparently in perfect health. The abdominal cicatrix had yielded to some extent, producing a ventral hernia. This was the result of a cough which had troubled her for some months and imperfect suturing, but the hernia occasioned no inconvenience and was kept in place by an abdominal belt. Two years after the operation this patient called on me concerning her ventral hernia. During this time she had felt strong and well, had led an active and happy life, and had performed all the duties of her household. Lately a troublesome cough had led to a marked increase in the size of the hernia and her belt had ceased to be a sufficient support. She was anxious to have the hernia radically cured, and considering the trouble which it was causing, the certainty that it would get worse, and the

axons. It is especially when the temperature reaches 41° and is maintained at that level for some hours that lesions analogous to the experimental ones are seen and these resemble those of the second experimental group. The accompanying figures represent the principal changes which I have observed in some of the cases which I have lately had an opportunity of examining, and for the clinical references in these I am indebted to Dr. W. Pasteur and Mr.

FIG 2

Dr Murray Fig 2 represents the appearance of two normal cells which stain evenly and show a regular distribution of chromatin granules. Fig 3 shows the appearance of cells taken from cases of

FIG 3.

Appearance of cells from two cases of meningitis recently under the care of Dr W Pasteur. A and B were from a case of moderate pyrexia in a child aged 14 months. C is from a case of chronic meningitis with marked hydrocephalus and abnormal temperature in a child aged one year. The cells stained in patches of different intensity. There was no differentiation of the chromatin rods. The nucleus was absent or ill-defined. The nucleolus was sometimes displaced as in C.

meningitis with hydrocephalus A and B were from a child suffering from postero basio meningitis with some hydrocephalus and moderate pyrexia C was taken from a child.

FIG 4

Appearance of cells from a case of septicaemia with high temperature (106° F) in a child, aged five years, recently under the care of Dr W Pasteur. The cells stained deeply and diffusely. The nucleus was ill-defined. The nucleolus was variable but as a rule was not altered. The brain were much thickened and firmly adherent to the meninges. The membranes of the

brain substance. The changes in the cells of this case were not so advanced as in the other and in this respect it was interesting to note that whereas in the other case there was moderate pyrexia, in this one the temperature was subnormal, or at the highest normal, throughout the disease. The stain in these is distributed in patches of varying intensity, the chromatin granules have lost their differentiation, the nucleus is not indicated, and in some cells (as in C) the nucleolus is displaced. The cell A shows a dark band running across it which would seem to correspond with that mentioned above as described by Marinesco as a rare occurrence in his experimental hyperpyrexial cases. Fig 4 represents the cerebral cells of a child who died from acute septicaemia, there was a continuous high temperature for some days before death which occasionally reached 106° F. Many of the cells were swollen and misshapen and they stained deeply and diffusely, presenting a plain dark blue appearance with no differentiation. In some the axis cylinders were also swollen and deeply stained and the nuclei and in some cases the nucleolus were often invisible. Fig 5 shows cells from a fatal case of tetanus. The chief

FIG 5

change is an extensive loss of colouring matter and the cells presented a spongy appearance with a white background which had a very striking effect but one which it is not very easy to reproduce. This condition was present in the motor area of the brain and the anterior cornua of the cord and to a less degree in the cerebellum. In these observations I have made special use of the valuable method of examining cells without the intervention of hardening reagents as described by J Turner by which beautiful specimens can be obtained and many possibilities of artificial alterations are avoided. But besides alterations which may be possibly produced in the preparation of specimens another fallacy—viz, that of post-mortem changes—has also to be carefully avoided and in order as far as possible to avoid these I made various control experiments by keeping pieces of brain under various conditions for different lengths of time, and in no cases was I able by the fresh method to produce any of the characteristic and definite changes which I have described above. The cell body, however, is not the only part which is affected by disease and indeed in many cases it is probable that the earliest changes take place in the delicate protoplasmic terminations of the dendrons. An interesting investigation has recently been made by Hamilton K Wright in this connection on the action of potassium bromide, and this observer concluded that the power which this drug has of inhibiting the intellectual and motor processes depends upon its action on the ultimate of the protoplasmic extensions, while the cell bodies only suffer after a more prolonged exposure to its influence. It is to be hoped that further investigations in these directions may eventually lead to a more definite knowledge of the pathological conditions underlying many obscure diseases and so finally to their more effective treatment.

ON THE STRUCTURE OF BRAIN CELLS AND THEIR DEGENERATION IN GENERAL DISEASES¹

By H CAMPBELL THOMSON, M D, M R O P LOND,
PHYSICIAN TO OUT-PATIENTS TO THE HOSPITAL FOR EPILEPSY AND
PARALYSIS, REGENT'S PARK, PATHOLOGIST AND CURATOR OF
THE MUSEUM TO THE MIDDLESEX HOSPITAL.

A TYPICAL brain-cell consists of a cell body together with its various prolongations. These prolongations are of two kinds—(1) short branches which ramify around the cell and carry impulses to it, and (2) one (sometimes more) long branch which carries the impulse from the cell towards its destination. The short branches are called dendrons, the long one is called the axon, and the cell body, together with its dendrons and axon, is known as a neuron (Fig 1). The

Diagrammatic representation of a neuron. A, Axon. D, Dendrons.
C, Cell body.

method of staining nervous tissues by silver salts, which was first introduced by Golgi, has shown that each neuron is an anatomical unit—i.e., its branches are in contiguity but never in actual continuity with those of neighbouring cells. Such an important discovery naturally greatly altered the ideas which were generally held concerning the modes of action of the nervous system, for it was formerly thought that the branches all joined with each other to form a complete network along which impulses freely passed, choosing their paths according to the different resistances which they encountered. The independence of the neurons explains clearly how secondary degenerations are limited. For example, the motor system is made up of two sets of neurons, an upper and a lower, the upper neuron has its cell body in the cerebral cortex and thence the axon travels downwards until it ultimately terminates by fine branches in the anterior cornua of the spinal cord. The lower neuron has its cell body and dendrons situated in the anterior cornua of the cord, while its axon makes its way outwards to convey the motor impulses to the muscles. Now according to the old idea the terminal fibres of the upper neuron were directly continuous with the dendrons of the lower neuron and therefore it was difficult to explain why, as a rule, degenerations of the upper did not spread into those of the lower since they were continuous, on the other hand, if we are right in believing as we now do that they are not continuous the degeneration of the one would naturally not spread to the other but would become arrested when its own limits were reached.

The axon is the chief prolongation of the cell body, it usually arises by a conical stem, becomes medullated, generally runs a long course and does not branch until it has nearly reached its termination. Some fine fibres, however, called collaterals sometimes spring at right angles from it during its course, but these can only be traced for a short distance and their termination is at present uncertain.

The dendrons are fine protoplasmic processes which

rapidly branch after leaving the cell body, and their branches are covered by minute processes which terminate in little varicosities. These were first described by Ramon y Cajal and were for some time thought to be artificial products brought about by the method of staining, but their regular and unvarying distribution together with the fact that they have been observed with other stains besides the silver one makes it probable that they are in reality a part of the cell. A good deal of importance has been attached to these little processes and their bead-like extremities are thought by many to be the means by which the nerve impulses are received from the corresponding processes of neighbouring cells. Stefanowska² found that these processes are not present in the mouse at the time of birth, but are gradually developed from 10 to 15 days afterwards. The function of the dendrons is doubtless one of conduction and in some cases it has been stated that fibrils have been actually traced from the dendron through the cell body to become continuous with those of the axon, if this proves to be generally true it will go far to show that a nerve impulse has its origin in the extremities of the dendrons and not in the cell body itself.

The cell body varies very much in shape and its structure can be studied by staining it with methylene blue after the method of Nissl. When treated in this way the cell body is found to consist of two substances—one which stains and another which does not. The chromatic or staining substance is usually arranged more or less regularly in rods or cubes, but the appearance may vary a little according to the methods by which the specimens are prepared. The achromatic substance forms the framework and is probably concerned with the conduction of impulses across the cell body. Opinions are a good deal divided as to the importance of the chromatic substance, or chromatophile granules, as they are often termed. Van Gehuchten considers it is one of the principal constituents of the cell, forming a reserve substance which accumulates during rest and diminishes during functional activity, and Lugaro also supports this view. There is usually a very distinct nucleolus in the cell body which stains deeply and this is surrounded by a lighter zone which represents the nucleus. Many of the cells contain a quantity of pigment, but the significance of this is not determined, for while some think it a sign of degeneration others ascribe it to activity. Whatever the uses of the separate constituents of the cell body may be its chief function as a whole is one of nutrition, for whenever any of its processes are cut off from it they always die.

Pathological changes have been observed in the cell body and its processes both in mental and general diseases and I can confirm some of the changes which take place in the latter from my own observations. The principal changes which have been observed in the cell body are alterations in the quantity and distribution of the chromatophile substance and the two conditions which seem to favour this are toxæmia and a high temperature. In man it is usual to find these two conditions existing together, but in animals the one may be experimentally obtained without the other, and according to Marinesco the effects produced are distinctly different in the two cases. Marinesco³ has studied the changes which take place in the cells of the central nervous system after an animal has been exposed to high temperatures and he has described three stages of degeneration which he thinks may be recognised. The earliest lesion consists of a circular and segmentary distribution of the chromatophile elements; next the cell body becomes swollen, stains diffusely, and the granulations cannot be separately defined, while the third stage is characterised by a still greater accentuation of these appearances—i.e., great opacity of the cell body which is often most dense round the neighbourhood of the nucleus but at other times occurs over other parts of the cell. More rarely there were dark bands running across the cell which were often zigzag in shape. These three degrees naturally pass imperceptibly into one another without any definite line of demarcation. Marinesco concludes from his experimental work that a temperature lower than 40° C, even when prolonged several days, does not seem to produce lesions like those determined by experimental hyperpyrexia and that in infectious febrile states when the temperature has exceeded 40° lesions can be recognised which do not always correspond to hyperpyrexial ones and these are doubtless produced by

It is especially when the temperature reaches 41° C. that the experimental ones are seen and these resemble those of the second experimental group. The accompanying figures represent the principal changes which I have observed in some of the cases which I have had an opportunity of examining, and for the clinical references in these I am indebted to Dr W. Pasteur and Mr.

FIG. 2.

The irregular development had occurred and who shared it with her father and her father's cousin whose hands were described as being exactly similar. The deformity appeared to be as I described it and as the illustration indicated, the ring finger being the only one fully developed on either hand, the remainder being unequally grown. The condition is symmetrical. My description, however, seems to have been as unconvincing as the illustration and in at least one book (Mr. Tubb's, for example) the case is described as one of overgrowth of the ring finger, the implication being that the other fingers are normal. Mr. Tubb borrowed and copied my illustration but reversed my description. I have been at some pains to trace the girl in order to see what is the exact condition by a skiasgram and Miss Knight of the Park Lane Day Industrial Schools here, where the girl formerly attended, has been good enough to find her to enable me to get the accompanying excellent skiasgrams which I owe to Mr. Thurstan Holland.

The condition disclosed is remarkable. It will be seen that the thumb and ring finger of each hand are apparently the only properly developed digits. The second phalanges of the first, second, and fourth fingers are abortive. It would appear that the epiphyses in the first phalanges of the first and second fingers are larger than usual, but I do not quite know how to describe the condition otherwise—the girl is now in her eighteenth year. I am disposed to accept the opinion of Mr. Douglas Crawford that when the terminal joint was formed there was no complete division of the cartilage and that the nutrient supply in consequence suffered. I think we may take it that the condition is asymmetrical, though it is not so obvious in the left index finger as in that of the right hand. The hands seem normal in other respects, as is the girl except for some deflection of the nasal septum to the left.

ECLAMPSIA, INDUCTION OF PREMATURE LABOUR, RECOVERY

By W. ORESWELL HOWLE, L.S.A. LOND

I THINK that the following case is worth recording because of the recent correspondence on this subject and the almost immediate relief after the birth of the child.

On March 4th, 1899, I was called to a woman whom I found to be suffering from a well marked eclamptic seizure. I learned from the friends that she was eight months pregnant with her first child and that her age was 25 years. There was no family history of convulsions and the patient had never had a "fit" before. On the previous day she had suffered from epigastric and lumbar pain, there had been no eye symptoms, headache, or vomiting. At 9 P.M. she was suddenly seized with a convulsion which was followed by unconsciousness. Between 9 P.M. and 4 A.M. on March 5th she had four "fits" and was insensible the whole time.

On examination I found the temperature to be 103° F. The tongue was nearly bitten through and there were profuse frothy discharge from the mouth, great cyanosis, sweating, oedema of the legs, and a good deal of pulmonary oedema. I immediately administered chloroform and continued for half an hour during which time she had three convulsions and an involuntary discharge of urine and faeces. The pulse was 120, small, very feeble, irregular, and compressible. 10 minims of tincture of veratrum viride were given hypodermically and the pulse rate dropped to 110 per minute. After consultation with Mr. Pooler, deeming delay dangerous, we decided to empty the uterus as quickly as possible under chloroform. The os was tightly closed. The position was right occipito-anterior. The pelvic diameters, though no pelvimeter was used, were considered to be normal. We decided upon manual dilatation. In 65 minutes we had dilated sufficiently to introduce the hand. Version was being quicker than extraction by forceps, time being all important. The child, a male with one testicle descended, was stillborn and weighed five and a half pounds. There was very little liquor amni. 1 lb. gr of citrate of ergotin was now given hypodermically and the placenta was expressed by Crêde's method. The uterus was washed out with one in 60 carbolic solution and contraction was well maintained. There was very slight post-partum hæmorrhage, the blood being dark coloured and slow to coagulate. The condition of the patient was now somewhat improved. The temperature was 103° and the pulse was 100, regular, not so compressible, but still small and weak. The cyanosis was not so marked, and there was no recurrence of the convulsions but the insensibility was profound. A quarter of a minim of croton oil in sugar of milk was administered on the tongue. By 8 A.M., or two hours after the birth of the child the cyanosis had entirely disappeared. The pulse was 96, of better quality, and we considered it safe to leave the patient. At 3 P.M. there had been no more convulsions. The pulse was 98 and the temperature was 99°. The patient was still unconscious. There was no post-partum hæmorrhage. At 8 P.M. there was a slight return of consciousness. A volun- tary discharge of urine took place, being eight ounces in quantity and dirty white in colour, its specific gravity was 1030 and it contained 3 per cent. of urea, 12 parts per 1000 of dried albumin measured by Babcock's albuminometer, no casts, and urates. A mixture containing 10 minims of tinc- ture of veratrum viride and five grains of hydrate of chloral was given hourly. During the following 24 hours the patient gradually recovered consciousness but had no memory of events later than eight days before the onset of the con- vulsions. She had no convulsions. She passed 20 ounces of urine of specific gravity 1030 and containing urea (2 per cent), urates, and dried albumin (two parts per 1000), no casts or progress since has been steady, there have been no more convulsions, the albumin has gradually disappeared, the quantity of urine has gradually increased, and the memory has returned. The patient left her bed on the fourteenth day and the convalescence has been uninterrupted.

This is a comparatively frequent complication of preg- nancy. Statistics vary from Auvar's¹ three in 1000 to those

¹ Traité Pratique d'Accouchements.

of the Philadelphia Board of Health, one in 170, but the affection is of such a serious nature that every case seems worthy of record. The percentage of deaths is estimated at between 50 (Pajot) and 30 (Kaltenbach). All observers agree that the primipara is much more liable to this condition, and plural births especially predispose to it, the above case being an exception. The extreme rigidity of the os in this case under profound anesthesia was remarkable, remember- ing that the tendency of eclampsia is to expel the uterine contents. With a group of symptoms including high temperature, great cyanosis, profuse discharge from the mouth, profound stupor, and pulmonary oedema authorities tell us to expect a fatal termination, and the rapid improve- ment after emptying the uterus was most gratifying, though after this has been done. The tincture of veratrum viride introduced by Dr. Baker of Eufaula, Alabama,² and revived by Dr. Squibb³ is of undoubted use because of its effect on the circulation and it is well to remember that it takes half an hour to act. Numerous observations on the use of this drug have been recorded⁴ lately and it has become a very valuable addition to our pharmacopœia. Birmingham.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF COMPLETE OCCLUSION OF THE OS UTERI

By T. W. PARKINSON, M.B., O.M. EDIN., D.P.H. ABERD.

On May 2nd, 1899, I attended a woman, aged 43 years, a primipara, who had been in labour about six hours when I arrived. The pains were almost constant, not permitting of any uterine relaxation the whole time during which I remained with her. She complained very much of a tearing pain in the region of the bladder. Upon ex- mination I found the vulva to be a good deal swollen, the vagina hard and dry, and the perineum very thick and rigid. I found the head presenting but entirely covered by the distended cervix. I could find no os uteri, but this did not surprise me as I concluded that it was too high to reach. I was very much struck, however, by the dryness of all the parts and by the head being so low without dilatation of the os uteri. In three hours I returned and found the bulging head lower but no os uteri. The pain in the lower part of the anterior abdo- minal wall was now unbearable. Under chloroform I made a thorough examination and found complete occlusion of the os uteri with just the smallest of dimples to indicate its posi- tion. I relaxed the cervix and permitted the pains to begin again and as soon as the cervix became tense over the presenting part I forced my finger with a sharp nail through the cervix and afterwards through the membranes. The water escaped and the pain stopped for half an hour. There was a good deal of bleeding. The rupture through the cervix took a somewhat triangular shape. As soon as the pains began again the artificial os uteri dilated rapidly and I delivered with forceps as the patient was much exhausted. She made a good recovery and is now quite well.

A CASE OF UNEQUAL GROWTH OF FINGERS

By G. A. HAWKINS-ANDLER, F.R.O.S. EDIN., DEMONSTRATOR OF ANATOMY AT UNIVERSITY COLLEGE, HONORARY SURGEON TO THE SANITARIAN HOSPITAL FOR WOMEN AND ASSISTANT SURGEON TO THE STANLEY HOSPITAL, LIVERPOOL.

IN THE LANCET of Feb 4th, 1893, I published a note on this case which was illustrated by an engraving (taken from a photograph) of the hands of a young girl in whom

[illegible]

supporting the injured hand on her lap and alternately flexing and extending the hand and fingers as if testing their movement. The appearance of the injury is seen in the accompanying illustration. On the back of the wrist just above the joint a prominence was formed by the displaced radial bone visible and slipped up over the posterior surface of the radius and ulna. On the palmar surface the ends of the bones of the forearm were prominent the projecting styloid process of the ulna being distinctly seen. The relative positions of the two bony processes were unaltered. The palm of the hand was swollen. Movements in the wrist were naturally diminished but the fingers moved freely.

Reduction of swelling and some pressure over the carpus was very easy but on removing the force the bones slipped back again to their normal position and it was after this second dislocation that the photograph was taken. After another reduction ordinary anterior and posterior splints were applied with a pad of lint over the dorsum of the wrist. The interest of the case lies in the fact that considering the age of the patient and the nature of the injury the result was dislocation and not Colles's fracture.

ST. BARTHOLOMEW'S.

The Editor

OR

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

It is a common error to suppose that the only cause of a dislocation of the wrist is a fall on the back of the hand. In the case of the patient described above, the cause was a fall on the side of the hand.

ST. BARTHOLOMEW'S HOSPITAL.

THE CASE OF A FEMALE PATIENT OF THE HOSPITAL WAS COMPLICATED BY A FRACTURE OF THE MIDDLE TEMPORAL BONE, AND IN WHICH THE VESSEL WAS LACERATED.

(Under the care of Mr. HOWARD MARSH.)

It was the case recorded below the time of onset of unconsciousness was many to the head was typical of meningeal hemorrhage, for in each there was a clear interval of consciousness between the infliction of the injury and the coma. Although in the second case death ultimately occurred the regaining was clearly indicated by the symptoms which were present. The difficulty now with us is the first case in which the bone which had been removed is certainly very unusual. The prognosis in these cases of extra-dural hemorrhage is generally very doubtful, for it is rarely possible for the surgeon to find out that the base is not fractured or the brain itself much damaged.

CASE 1.—A man aged 34 years, having been knocked down by a car on the street at 9 A.M. on Feb. 7th, was taken to St. Bartholomew's Hospital. To details of the accident could be obtained. On his arrival he was perfectly conscious, possessed his limbs and was anxious to return home, but he was not allowed to do so. He had a superficial scalp wound over the right parietal eminence and there was bleeding from the right ear. At 9 A.M. he began to be drowsy and gradually became unconscious. There also developed complete paralysis of the left arm and leg and right side of the face, so that the head was pulled out with each expiration. The pulse went down to 35 and the breathing approached the Cheyne-Stokes type. The right pupil was widely dilated. On reaching the hospital Mr. Marsh found the patient apparently dying. As quickly as possible a large flap was raised and the skull was exposed in the right temporal fossa. It was then seen that there was a linear fracture extending this was obliterated from below upwards and backwards, and so placed that it crossed the anterior inferior angle of the parietal bone. A large trephine was applied with its centre one and a half inches behind the external auditory process and the same distance above the zygoma. Through the opening thus formed a large extra-dural blood-clot was exposed. The vessel was about two and a half inches thick at its centre and about four inches across, was removed

with the finger and a large Volkmann's spoon. It could not be seen that the dura mater had been separated from the skull and forced inwards into the brain for at least three inches over a considerable area, so that a artery was torn large enough to hold about eight ounces of the middle meningeal artery had been torn from its groove in the parietal bone and carried inwards with the dura mater. The vessel was captured and free bleeding was arrested by passing a ligature round it. In consequence of the wide separation of the dura mater and the depth from the surface at which it lay the bleeding artery could not be tied until more room had been obtained by enlarging the trephine opening. It was then, however, easily seized with clip forceps and tied with fine silk. The bone removed could not be replaced in the trephine opening for the dura mater having been so much depressed by the blood-clot there was nothing on which, whether while it was entire or when it had been cut into fragments (the method, apparently by which necrosis is most likely to be prevented) it could have rested. The scalp-wound was closed except at its centre. No drainage tube was used. Soon after the operation the pulse rose to 120. During the night there was a considerable discharge of what seemed to be coagulated fluid from the wound, enough at the time of the operation no laceration of the dura mater was observed. This continued for three days. On the day following the operation the patient had regained consciousness but was so restless that a hypodermic injection of morphia one-fifth of a grain was given. This acted very favourably and was afterwards once or twice repeated. Movement was regained in the left leg on the fifth day after the accident; in the arm movement began to return only on the thirteenth day. The patient completely recovered and was discharged from the hospital at the end of a month.

CASE 2.—A man aged 25 years, was struck on the head by a large block of wood which fell from a crane beneath which he was standing. On his admission into St. Bartholomew's Hospital no fracture of the vault of the skull could be detected, but there was free bleeding from the nose and into the pharynx. The patient was dazed and very restless. Soon afterwards swelling from extravasation of blood appeared on the left side of the head in the temporal region and he became unconscious. It was decided that although in all probability there was fracture of the base of the skull extending upwards into the temporal region, an exploratory operation ought to be undertaken. When the skull in the temporal region was seen exposed a comminuted fracture was discovered involving the parietal, and the squamous portion of the temporal bone. When a crown of bone had been removed with a large trephine an extensive extra-dural blood-clot was found and when this had been cleared away the middle meninges were seen lying on the surface of the dura mater and all bleeding from its proximal end. During an attempt to place a ligature round it the vessel gave way and became retracted beyond reach. Hemorrhage, however, was easily arrested by gently plugging the space between the bone and the dura mater with sterilised gauze. During the operation it was noticed that bleeding was still going on into the pharynx. The patient gradually sank and died the same evening. Post-mortem examination disclosed an extensive fracture of the middle lobe of the skull reaching up into the temporal region and wide laceration of the brain.

Remarks by Mr. Marsh.—Cases of laceration of the middle meningeal artery are not very rare, yet these two examples which occurred within a few weeks of each other may be worthy of a brief notice as they illustrate the different conditions under which the operation may have to be performed and the wide difference in the result which may, under different circumstances, be met with. In Case 1 it seems probable that the patient had sustained a fracture of the base of the skull, for the fracture in the temporal fossa was a mere fissure which could scarcely have been produced by direct violence, and there had been bleeding from the ear. The brain, however, was uninjured at the time of the fall, though it was severely compressed by the blood-clot which subsequently formed. Such a case as this was altogether favourable for operative treatment provided that acute asepsis was maintained; and no case could more fully illustrate the propriety with which the contents of the cranium may be treated when the brain has escaped medical injury. Case 2 belonged to a different class. The original accident had produced injuries to the

EPIDEMIOLOGICAL SOCIETY

Enteric Fever in the Netherlands

A MEETING of this society was held on May 19th, Dr FRANKLIN PARSONS, the President, being in the chair.

Dr R H SALTET, Professor of Hygiene in the University of Amsterdam, read a paper on Enteric Fever in the Netherlands, freely illustrated by maps and statistical tables, graphs and numerical. Before entering on the subject, which he thought might throw some light on the causes and spread of this disease, he wished to describe the sanitary organisation of his country. The kingdom was divided into seven provinces and subordinated to the provincial councils were those of the 1123 municipalities which with populations ranging from 200 to 500,000 were alike constituted of elected members presided over by a burgomaster nominated by the Crown. These were the sanitary authorities, but the only official medical advisers were seven appointed by the Government and one by the municipality of Amsterdam, on whom devolved not only the supervision of the public health but the work of registration of births and deaths, the inspection of asylums, and the control of the medical profession. The census was decennial, but since besides the prompt registration of births and deaths every change of domicile was notified to the local authorities the population of every district was always known with a considerable degree of accuracy. The causes of deaths, classified under 34 headings which had been unchanged since 1875, were certified by the medical man in attendance or, in the absence of such, by one appointed by the local authority to hold an inquiry, and in cases of a suspicious character after a judicial investigation. Notification of infectious diseases had been obligatory since 1872 but was not complete, for many practitioners did not believe in the communicability of typhoid fever and some connived at the concealment of cases occurring in houses of business on account of the injury consequent on the regulation requiring a notice of the fact to be affixed to the premises. Typhus fever, typhoid fever, and so-called continued fever were not strictly distinguished, some old school practitioners applying these names to severe, mild, and doubtful cases respectively. In his opinion cases of such infectiveness as to attract the medical attendant or nurses might be fairly assumed to be typhus fever, but these were few, so that allowing for those of typhoid fever which were not notified the total deaths returned under the three descriptions represented approximately the true mortality from enteric fever. Dividing the period 1875-95 into four quinquennia and taking the death rate per 100,000 population in each, he proceeded to inquire in the first place whether the causes of the decline in the mortality from typhoid fever were no other than the better social and sanitary conditions which had tended to lower the general death rate of the country. This did not appear to be a sufficient explanation, for while the general death rate had declined by 14 per cent and that from tuberculous diseases by 16 per cent the reduction in the typhoid fever death rate had been no less than 63 per cent. Next, as to the aggregation of population in towns, while the urban death rate was always somewhat higher than that of the rural districts it had fallen by 20 per cent, as against 12 in the country, and as regards typhoid fever by 72 and 60 per cent respectively. It was worth consideration that though crowding favoured the spread of infection the residents in towns enjoyed many material advantages, and better medical attendance. Thirdly, could any relation be traced between the water supplies and the prevalence of fever? The water question in Holland was beset with difficulties. The most flourishing part of the kingdom lying below the sea level, with the subsoil permeated by salt water, the population had recourse to rain water stored in tanks, but in dry seasons they fell back on the polluted water of the canals and dykes, while elsewhere the towns found an unlimited but questionable supply in the rivers, and only on the higher lands could good drinking water be had from wells. Gradually, however, towns and rural communes with an aggregate population equal to 28.5 per cent of the whole had been furnished with good public supplies drawn from wells, and Rotterdam and other towns comprising 12.5 per cent of the population were supplied with filtered river water. Arnhem, Haarlem, and The Hague obtained their supplies from wells in the range of sand dunes skirting the sea coast. But no appreciable difference was noticed between the two classes, for the general death rate had

fallen 19 per cent in those supplied with ground water and 23 per cent in those supplied with filtered river water, the fall in the typhoid fever death rates having been 68 and 54 per cent respectively, but in the latter it had been considerably lower from the first. Since river water seemed more exposed to pollution than that from wells it was possible that the lower mortality among the population using it might be partly owing to the greater cleanliness attainable with the more abundant supply of water. Fourthly, there was the influence of the soil to which attention was first drawn by Pettenkofer, though its nature was still obscure. In the Netherlands the higher and drier provinces were, with the exception of Groningen poor and thinly peopled, the rich pasture land and flourishing centres of trade being for the most part below or little above the level of the sea. While however, enjoying many favourable social conditions these districts suffered from the disadvantages of an absence of running streams, the rivers so called being shut up within locks and of the instability of the peaty soil which precluded the erection of substantial buildings even with the aid of piles driven into the clay beneath, while the disposal of sewage and factory waste was beset with difficulties. The general death rate in the low lying rural communes, which was formerly higher than in the more elevated, had shown a greater improvement, but that from typhoid fever had declined almost equally in both. On the whole a fall of 72 per cent in the typhoid fever mortality among the urban population and of 60 per cent among the rural population seemed to suggest that while sanitary improvements had operated equally throughout, the progress of medical science, the benefits of which were enjoyed to a greater extent by the inhabitants of the towns, was a factor the influence of which was far more powerful than was commonly supposed.

Mr SHIRLEY MURPHY said that the great reduction in the mortality from typhoid fever of late years had in England and Germany been naturally ascribed to the introduction of better water supplies and sewage disposal, but after listening to Dr Saltet's able examination of the possible factors he could not but think that a partial explanation might be found in a diminished infectivity in accordance with Dr Whitelegge's doctrine of cyclical variations in virulence.

Professor NOTTER remarked that the stationary character of the population of the Netherlands would favour their acquisition of a degree of immunity, in India the extreme susceptibility of Europeans recently arrived was notorious, as was the rapid increase of resistance with each year of service or residence.

Dr THEODORE THOMSON, Dr CHRISTOPHER CHILDS, Dr WASHBURN, the PRESIDENT, and Dr WILLOUGHBY also took part in the discussion.

Dr SALTET, replying, explained that the wells were mostly from 100 to 120 feet deep in the superficial sand only, though as remote from habitations as possible while the river waters were subjected to sand filtration under regulated pressure and velocity. Typhoid fever in the Netherlands was mostly sporadic, epidemics being rare.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

Exhibition of Patients and Specimens

THE eighth ordinary meeting of this society was held on May 17th and was devoted to the exhibition of patients and specimens, Sir JOHN BATTY TUKE, President, being in the chair. Before entering on the work of the meeting the PRESIDENT made reference to the death of one of their oldest members, Dr John Moor, and it was resolved to send an expression of the sympathy of the society to the relatives.

Dr SHAW M'LAREN showed 1. A boy after operation for Congenital Torticollis. Instead of performing subcutaneous tenotomy the muscle was cut through by an open incision. No apparatus was applied and now the boy could turn his head well round towards the right. The right side of the face was noticeably larger than the left—a condition often noted in such cases. 2. A lad after operation for Ruptured Bladder. He was first seen 24 hours subsequently to his accident, having been run over by a cart. He was passing frequently small quantities of urine and a catheter passed easily into the bladder. The wound was found to be low down on the anterior wall at the junction of the bladder and urethra. The wound was drained through the perineum and naturally became septic. The patient was now almost well after having

been ill for some time. 3-A man, aged 70 years, after examination for tumor of the bladder. The only symptom

which showed itself in this case was a sudden and pro-
gressive enlargement of the prostate gland. The cystoscope showed the
presence of a villous tumour on the anterior wall. A vertical
incision was made over the pubes and the bladder was opened.
The tumour was drawn up and clipped off with scissors. It was found to be
a simple papilloma. A man with of standing Roth's
fracture of the tibia with backward dislocation of the
whole foot. Radiographs showed the condition well.

Dr. AFRICA stated that at the present time he had five
cases of diabetes in his wards, four being cases of diabetes
mellitus and one insipidus. I have of late diabetes
mellitus in a boy, aged 13 years. The case was only of two
months duration, the boy having been perfectly well pre-

The patient exhibited markedly the signs of diabetes—the dryness of the skin, the thinness of the face, and the rapid appearance. His weight was 45 lb. 7½ oz. The symptoms had been present for more than two years. He had passed as much as 240 ounces of urine daily, though now this had fallen to 120 ounces. There were over 30 grains of sugar to the ounce. He also showed evidences of peripheral toxic neuritis—e.g. pains in the limbs, sensory disturbances, together with atrophy of the optic nerve (no cataract). 3. Diabetes insipidus in a youth, aged 16 years. He had been ill for 18 months. No cause could be assigned for the case. Thirst and polyuria were the only symptoms. The urine passed had amounted to 650 ounces per diem, now, however, he passed about 430 ounces. The specific gravity was very low—1001. He was gaining weight. Dr. James exhibited 1. A case of Cretinism of the liver with abdominal and thoracic effusions communicating.

When first seen the patient was dyspnoeic from ascites and effusion in the right pleural sac. He was especially tired both in the chest and abdomen, but on each occasion the amount of fluid drawn off from the chest increased—for example on April 23 322 ounces and withdrawn on April 18, 1916, 292 ounces and on May 15, 1916 ounces. The pleural sac could now only contain about 120 ounces and therefore in emptying it the abdomen was also emptied at each of these operations. Dr James first thought that this must have been due to lymphatic absorption during the slow draining away of the fluid from the chest and by experiment that the pressure was taken the pressure in the thoracic fluid rose just as it did in the abdomen. In this case the pleural effusion has been some common—common as the posterior origin of the diaphragm. 2. A series of 17 ascitic tapings were performed. The effusion began to reaccumulate in the legs the fluid enlarged the peritoneal sac—fluid in the legs the peritoneal sac enlarged the peritoneal sac.

The patient was clinically short of than he had been
was hardly any serious matter in the renal phalanges.
The patient was distinctly shorter than he had been
Dr Allan Jamieson showed a boy, aged eight years, in
the early stage of Trophoblastic Leptosis. The patient
lived in British Guiana. The father was a mulatto but the
mother was fair. There was no hereditary history of leprosy
The disease was, however, endemic in Georgetown. The boy
six years ago slept with a nurse who was found to be suffer-
ing from a sore on the leg which was pronounced to be due
to leprosy in the ulcerating stage. Two years ago the
mother noticed the appearance of maculae on the face
and ears and was suspicious about them. She therefore
sent the boy home for observation. On the face and

On the bases there was a morbid like spot at the center of the scapula there was a certain dulling sensation, but it was not well marked. The hands were large and there was a degree of paralysis as the patient was not so active manually as he had been. The ulnar nerve was unaffected. 2. Two women with "identical Deformity of the face in both the carriage of the nose had been destroyed and the mouth

the center of these stains there was a certain dulling of sensation, but it was not well marked. The hands were free and there was no marked change in the

The patient was not so active manually as he had been. The ulnar nerve was injected 2 times.

almost identical Deformity of the Race in both the

cartridges of the nose had been destroyed and the mouth

Dr LITTLEDALE and Dr KIRKPATRICK made a communication on the subject of Room Disinfection, with Special Reference to the use of Formic Aldehyde.

Dr LITTLEDALE said that the experiments were carried out in a room having a capacity of 28 cubic metres (989 cubic feet), with no opening into it but the door, and 10 grains of formalin tabloids were vapourised in an "alformant" lamp. The yellow air coccus, bacterium coli commune, staphylococcus pyogenes albus, bacillus typhosus, pus, sputum, and putrid urine were the test objects exposed. Threads were steeped in emulsions of these various objects, wrapped in filter paper and lint, or concealed in the pocket of a coat or between the leaves of a book, or exposed quite open to the vapour. All the objects freely exposed were found to be quite incapable of growing on nutrient media after a nine hours' exposure to the formalin, but concealment in a coat-pocket or between the leaves of a book seemed quite sufficient to prevent their being acted upon to any degree, as all bacteria so exposed were not at all or only slightly hindered in their growth. The sputum was openly exposed on cover glasses, on which it had been allowed to dry in the oven at 37° C, and after exposure for nine hours no growth took place in broth for two days—that is, until the surface layer digested off and the deep surface was exposed, as could be seen by the shaggy appearance of the layer on the cover glass. Everything in the dried pus which was openly exposed on gauze was killed except a leptothrix. Agar tubes of definite dimensions were inoculated over a sloped surface for a known distance and exposed just immediately after inoculation, and after the experiment were kept at 37° C. Growths appeared in these tubes but not over the whole length of the smear. No inoculation experiments were undertaken on animals.—Dr KIRKPATRICK said that an efficient yet easily applicable mode of room disinfection was greatly needed for such chronic infectious diseases as tuberculosis and could hardly be obtained except by means of gaseous disinfectants. Professor Koch had shown that sulphurous acid gas was useless for practical purposes, while Dr Fischer and Dr Proskauer had proved that to apply chlorine and bromine efficiently was quite as difficult as to disinfect with germicidal solutions. The disinfection of rooms, by means of formic aldehyde generated by Messrs Zimmermann's "alformant" was very much simpler than any other of the modes of gaseous disinfection considered, while it was superior to any of them in point of efficiency.—Dr NINIAN FALKNER, Dr KNOTT, and Dr TWEEDY having discussed the subject, Dr KIRKPATRICK, in his reply, stated that six or seven hours would be sufficient to thoroughly disinfect with formalin vapour, and on opening the doors and windows after this the smell at once disappeared, which was not the case with sulphurous acid or other gaseous disinfectants.

Dr MARTLEY read a paper on Cancer in Ireland. After contrasting the deaths from cancer in Ireland and England—the former rate being roughly only 70 per cent of the latter—he illustrated by maps its very unequal incidence in different localities, the parts most affected being the east of Ulster, Dublin, and Carlow.—Dr T W GRIMSHEAW, O.B., Registrar General, remarked that maps showed that cancer was prevalent in most Anglicised parts of the country, for example, they might look at Carlow, which they knew to be an old English colony, and Dublin, containing a large proportion of the population of English descent.—Dr JOHN W MOORE explained the preponderance of cases in Dublin and Belfast by the fact that in country districts the medical men were often reluctant to give cancer as a cause of death owing to the existing dread of the disease on account of its hereditary nature, also the diagnosis of cancer was usually verified in the city hospitals by a necropsy, which was not the case in the country, in addition, Dublin and Belfast received cancer patients from all parts of the country.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on May 19th, the President, Mr D H Goodsall, being in the chair.—Mr W Campbell McDonnell showed a man, aged 64 years, with some Atrophy of the Muscles of the Left Thigh, resulting from Sciatica of five years standing. This wasting was held to be a reflex result of the peripheral irritation.—Mr Reginald Brown read notes of the following cases:—
primipara, conjugate
aged 22 years, with a
of 8.3 centimetres

used did not advance the head. Perforation was accordingly resorted to and delivery effected easily. 2 A multipara, aged 34 years, with a Flat Pelvis having a true conjugate of nine centimetres, whose child was delivered by version.—Dr Durno read notes of a case of Excision of the Breast of a Woman, aged 45 years, for Scirrhus. There was profuse recurrent hæmorrhage which was stopped by the local application of turpentine and re dressing to be soon followed by a fresh outburst in alarming quantity for which the local application of tincture of perchloride of iron and a saline enema sufficed with the wound left open. Epistaxis occurred next day, so the nares were plugged and a saline enema was again used. Uterine hæmorrhage varied the site next day and was controlled by a crystal of iron alum. The patient ultimately recovered.—Dr J R Conner read notes of a case of Post-Influenzal Phlebitis in a man, aged 31 years, whose left calf swelled on the twenty second day after influenza. A few days later the thigh swelled and the superficial femoral vein could be felt to be hard. Pressure made on this thrombosed vein produced swelling of the leg, superficial veins suggesting canalisation of the clot. In 17 days from the onset of the phlebitis the swelling of the leg had almost disappeared.—Mr E O Hearne showed a boy, aged 16 years, with the right leg reaching just below the left knee and having a ball and socket hip-joint, a normal ankle, two bones running throughout, but no knee-joint. The right hand had a thumb and three fingers, of these the third and fourth were webbed. The left hand had no thumb, no carpus, and three fingers, two of which were webbed. The left ulna and radius were much dwarfed and curved.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The eighth meeting of the session was held in the medical library of University College, Bristol, on May 10th, Dr A. J Harrison being in the chair.—Mr J L Firth showed a patient with Cervical Ribs.—Mr Paul Bush showed a patient with Displaced Scapula.—Dr W H Newnham showed a specimen of Intra peritoneal Hysterectomy.—Dr T Fisher showed the following specimens: (1) Pancreas containing Calculi, (2) Malignant Growth of the Cæcum, (3) Sarcoma of the Ileum, (4) Fibrous Myocarditis, and (5) Lungs with Broncho-pneumonia breaking down into Cavities.—Dr B Rogers showed some microscopic slides with Liver Disease.—Dr E Stack showed a most interesting series of Kidney Specimens.—Dr W H Newnham communicated a paper on Removal of One Ovary, with an account of cases.

Reviews and Notices of Books.

A Text-book of Organic Chemistry By Professor VICTOR VON RICHTER. Edited by Professor R. ANSCHÜTZ of the University of Bonn. Translated by EDGAR F SMITH, Professor of Chemistry in the University of Pennsylvania. Third American (from the Eighth German) Edition. Vol I. Chemistry of the Aliphatic Series. London: Kegan Paul, Trench, Trübner, and Co, Ltd. 1899. Pp 625. Price 15s.

We doubt whether there is a chemist living whose opinions on organic chemistry are more respected than those of Professor von Richter. That being so, it is not surprising that his well known text-book on the chemistry of the carbon compounds has reached in the language in which it was originally written eight editions and still less surprising is it that this work should have been translated into English. The volume before us is the third American edition and its title-page bears the names of three well known chemical authorities, Professor von Richter himself, Professor R. Anschütz the editor, and Professor Smith the translator. The volume deals with the chemistry of the aliphatic series, the fatty substances, or what may be called the alicyclic carbon derivatives which contain open carbon chains, as distinguished from the aromatic or benzene compounds, the cyclic compounds of carbon, which contain closed carbon chains. Volume II of the work which is in course of preparation will be devoted to the aromatic series and it is hoped that the work will be published during the

the West and East, for the Use of Students and Others

Modern Drainage Inspection and Sanitary Surveys By
GERARD J. G. JENSEN, C.E. London The Bantam
Publishing Company, Limited 1899 Price 2s 6d net

This book is thoroughly in accord with its title, being a most useful guide for those upon whom devolves the responsibility of planning or inspecting systems of drainage. Though terse very little that is necessary for guidance is omitted, the work being evidently the outcome of much practical experience of the subject treated. Mr. Jensen first draws an ideal picture of what a sanitary inspector should be, but it is to be feared that few will fully attain to it.

The book, which is very systematic in arrangement, first reviews some of the various appliances used in drain testing, &c. The course is next pointed out and the various defects to be expected are described, while suggestions are made for their removal or remedy. Several illustrations both of defective and approved appliances showing the most desirable arrangements under varying conditions of space are given, together with sundry block plans showing the most desirable arrangements already spoken of. There is a portion where the discussion drawn by Mr. Jensen is not quite apparent—viz., why on page 42 he so strongly and properly objects to the stop sink delivering over a gully while on page 48 he advocates that urinals should always do so.

A capital chapter furnishing hints upon fixtures and notes and paragraphs is illustrated by examples which many engaged in such work might study both to their own and to their readers' advantage. The book is convenient in size for the pocket and we can strongly recommend it.

repent of a portion of the author's treatises on the "Transectio-
separation of the Erythraeae. It deserves, however, to be
presented in this separate form, for it should prove of value
to lecturers on anatomy, as the plates show very clearly the
processes of ossification of the bones of the hand, the wrist,
and the distal ends of the radius and ulna. A description
is given in the text of the development of each bone and
the plates, which are reproductions of skiaograms, illustrate
the appearance of centres of ossification and the times when
they join. There are in all 19 skiaograms of the hand and
wrist at various ages.

Animal Simplex Approved for Modern Uses of Cure By
W T BERNIE, M.D. Durb. Bristol J Wright and Co
1899. Price 6s.—Although we cannot, like Dr
Bernie, approve of animal simples for modern uses of cure
at least in every case, yet we must thank him for having
collected for the general reader a vast amount of entertain-
ing lore. There are but few of us who have the opportunity
or the leisure to read through the pages of that immortal
work "The History of Four footed Beasts" by Topsell or
the many seventeenth and seventeenth century popular works
on Physics. Dr Bernie, however, has extracted the salient
parts of such works and arranged them in a handy form
for reference.

The Chemical and Biological Analysis of Water By T H
PEARMAIN and O G MOON, M.A. London. Baillière,
Tindall, and Cox 1899. Pp 172. Price 4s.—This
is Part II of a work undertaken by these authors on
the analysis of foods and drugs. Part I was devoted to
milk and milk products which has already been critically
noticed in our columns. Part III dealing with foods and
Part IV dealing with drugs are in preparation. The
volume before us will be found a useful guide to those under-
taking the chemical and biological analysis of water. The
material is ably collated but the authors interpose with
general sensible remarks on the value of bacteriological
and chemical examination respectively. Their remarks on
the constitution to be put upon the results obtained from an
examination are fully in accordance with recent knowledge.

Chemistry for Photographers By CHARLES F TOWNSEND,
F.R.S., F.R.P.S. Second edition, revised. London
Dawbarn and Ward, Ltd. 1899. Pp. 168. Price 1s.—This
little work adequately fulfils the purpose for which it has
been written. Photographers, amateur or professional,
concerned in the production of a photograph and such
information should be easily derived from a perusal of the
pages of Mr Townsend's book. It is written to meet the
requirements of the average amateur and technician as
far as possible avoided. The book is well adapted for those
who prefer, figuratively speaking, not to work in the dark.
The fact of a second edition being issued tends to show that
this contribution to the chemical side of the subject is
appreciated.

The Essentials of Chemical Physiology By W D
HALLIBURY, M.D. Lond., F.R.S. Third edition. London
Longmans, Green, and Co 1899. Pp 199. Price 5s.—This
known manual. Recent advances in chemical physiology
have necessitated some revision in order to bring the work
quite up to date. Dr Halliburton as the result of con-
siderable teaching experience knows exactly how to bring
the subject in its practical relations before the student.
The book deals with facts rather than theory and in
a way which a student familiar with bench work cannot

fail to grasp Dr Halliburton divides his volume into two parts, the first comprehending an elementary course and the second an advanced course. In the appendix a description of the instruments and methods employed in physiological analysis are described. The book may be confidently recommended to the student who is anxious to commence a thorough and practical acquaintance with the essentials of chemical physiology.

Manual of Clinical Chemistry. By ELIAS H. BARTLEY, B.S., M.D., Ph.D. Philadelphia: P. Blakiston's Son and Co. 1899. Pp. 150. Price \$1.—In a review of Dr Bartley's text-book of medical and pharmaceutical chemistry which appeared in THE LANCET of March 18th, 1899, we suggested that the section in that work which dealt with physiological and clinical chemistry might form a separate handbook since the subject was so serviceably and suitably treated. The receipt from the publishers of the above manual shows that our suggestion has been adopted. We have nothing to add to our former remarks except that the book deals with a subject of first importance to the student of medicine and that in this manual he will find all the requisite facts and practical directions neatly and clearly placed before him.

Sewage Analysis. By J. ALFRED WANKLYN and WILLIAM JOHN COOPER. London: Kegan Paul, Trench, Trübner, and Co. 1899. Pp. 215. Price 7s. 6d.—We anticipated that we might have been able to congratulate Messrs Wanklyn and Cooper on adding something fresh to this important subject, but frankly we cannot. Indeed, it is quite an elementary book on the subject, in which one of the authors—Mr Wanklyn—takes the opportunity of making personal references and of emphasising his own contentions on his own pet subjects. He grumbles all through at the attitude of certain English chemists whose views differ from his own. He objects, for example, to the failure, as he calls it, of certain English chemists to express the results of the ammonia process on the only scale ever sanctioned by himself. He regards this "tampering with analytical results" as rapidly assuming the dimensions of a public scandal "and the originator of albuminoid ammonia warns those persons that the expression of the results in parts per 100,000 lays the analyst under the suspicion of representing the liquids as being ten times too pure." Again, he declares that the circumstances under which his work has been carried on—for example, the severance of all relations with the London Chemical Society—have operated advantageously to him. "The wave of fad and fallacy at present passing through the Chemical Society has not disturbed us in our laboratory." Then he tilts at the experiments of the late chemist to the London County Council in which purification of sewage by bacterial agencies was attempted and with some success. Mr Wanklyn scouts the idea of bacterial agencies affording a satisfactory solution of the sewage problem. In this we fancy he is quite alone. There are two points in the book which are worthy of note and which somewhat redeem it from the impression that there is nothing new in it. These are the significance of carbonic acid in sewage and the process elaborated by the authors for the estimation of organic matters by the moist combustion process. Mr Wanklyn has done excellent service in bringing forward methods for the detection of impurity in water and in sewage effluents, but he rather tends to belittle what he has done by taking up the futile and contentious attitude which marks his latest literary contribution.

Outlines of Physical Chemistry. By A. REYCHLER. Translated from the French by JOHN MCCRAE, Ph.D. London: Whittaker and Co. 1899. Pp. 268. Price 4s. 6d.—Physical chemistry is a branch of general science which has developed so much in recent years as to call for separate works on the subject. The little work before us is a translation from the French which had been commenced by

the late Dr Hurter whose untimely death, however, occurred soon after he had commenced this task. The work of translation was then taken up by Dr John McCrae who is the demonstrator of chemistry in the Yorkshire College, Leeds. We congratulate him upon the result. Though a small work it is divided into four parts, the first dealing with the elementary laws of chemical combination, the atomic hypothesis (surely this should be theory), the gaseous state, the specific heat of elements, and the constitution of the molecule, the second part with the gaseous liquid and solid states, the third with thermo chemistry, electro chemistry, and the nature of salt solutions, and the fourth with chemical equilibrium, chemical dynamics, and hydrolytic dissociation. The appendix contains amongst other things a table of atomic weights and a table of the heat of formation of salts. As we have said, the subject dealt with is of increasing importance and it is satisfactory to find that facilities for obtaining a sound and intimate acquaintance with the principles concerned are by means of this text-book afforded to the student.

Milk, its Nature and Composition. By O. M. AIKMAN, M.A., D.Sc. Second edition. London: Adam and Charles Black. 1899. Pp. 176. Price 3s. 6d.—Dr Aikman is a prolific writer on agricultural questions and the little volume before us is not the least important and interesting of his contributions. He writes scientifically, authoritatively, and clearly. The fact of a second edition of this little book being published speaks favourably of its reception. We thoroughly endorse the views expressed by the author in regard to the standard composition of milk. The following sentence, it seems to us, indicates a plain way out of the difficulties of establishing a definite standard: "Milk should be defined under the Sale of Food and Drugs Act as the normal secretion of the mammary glands of the cow." And he asks, Ought it to make much difference where the quality of the milk is so poor whether the sample has been adulterated in the technical sense—that is, been submitted to a watering process subsequently to its being obtained from the cow's udder or not? We would reply no, and we agree with Dr Aikman that it is obviously unfair that a person who expects to obtain ordinary milk should be provided with abnormal milk. This little work must be reckoned as one of importance to agriculture as the author writes in no uncertain terms on the subject both on the technical and scientific sides.

A Short Practice of Midwifery, embodying the Treatment Adopted in the Rotunda Hospital, Dublin. By H. JELLETT, B.A., M.D., Dub., F.R.O.P. Irel. With a Preface by W. J. SMYLY, M.D. Dub., F.R.O.P. Irel. Second edition. Illustrated. 1899. Pp. 380. Price 6s.—We are not surprised that this book should so soon have reached a second edition. It gives a clear and concise account of the teaching of the Dublin School of Midwifery and is an admirable manual for its size. In this second edition some alterations have been made in the arrangement of the chapters and some 60 pages of fresh matter have been added. The main features of the book, however, remain the same. A very interesting table is appended showing the nature of the cases, 11,958 in number, treated in the Rotunda Hospital during the 10 years 1889 to 1898. From this we find that the average morbidity—under this heading is included every case in which the temperature rose even once above 100° F.—for the 10 years is one in 13.8. The average maternal mortality during the same time is one in 169, or a percentage mortality of 0.62. A second table is given showing the cause of death in each of the 75 cases which ended fatally during this period. These two tables add greatly to the value of the book. They furnish us with a number of important obstetrical data and enable us to form a clear idea of the value of the treatment advocated.

THE LANCET.

LONDON: SATURDAY, MAY 27, 1899.

THE session of the General Medical Council will begin on Tuesday next at 2 P.M. The personnel of the Council is unchanged—save by the lamented death of Sir WILLIAM ROBERTS who never spoke much but whose quiet influence was always felt. His successor in the representation of the University of London is DR. FRY SMITH. The meeting promises to be a very busy and interesting one. It would not be difficult to name 16 or 18 subjects of great importance which will call for discussion apart from the penal cases and applications for restoration to the Register which generally take up two or three days of the Council's time. The subjects of epiruous diplomas, of unqualified dispensers, of instruction in vaccination under the new conditions of the Act of 1898, of the inspection of the documents of the Council, of procedure in penal cases, of the examinations of the Apothecaries' Hall of Ireland, of the amendment of the Medical Acts, of increasing the stringency of the preliminary examinations, of medical aid associations, of the HUNTERS case, and of an increase in the penal and disciplinary power of the qualifying bodies and of the General Medical Council, are all likely to occupy more or less of the Council's time, to say nothing of others which have been adjourned from past meetings. It would be well if the General Medical Council would take a lesson from the failures of another public body which is constantly overwhelmed with the variety of subjects which it undertakes to deal with and which by undertaking too much often does badly. It might do well. On the other hand, the critics of the Council will do well to recognise that in the very nature of things it cannot act with that precision and despatch which a body less complicated in composition and less vague in function and power might display. It has even more excuse for slowness in reform than Parliament has. It cannot make its own laws, it is, after all, an administrative and not a legislative body and must be taken and judged as such. It must be admitted that this is the view which is generally taken by the profession as regards the Council and in spite of occasional errors of judgment it reflects pretty truly the general opinion of the profession. The action of the General Medical Council in the matter of unqualified assistants is a good illustration of this statement. The Council was slow to recognise its own powers in regard to an admitted evil. For many years it used its powers very sparingly. At length it came to see that its powers were much greater than it had thought them to be and with two or three resolutions it abolished practically at a stroke the whole race of unqualified assistants.

It is probably owing to the representative constitution of the Council and to the slow and cautious use of its powers that the Government so frequently applies to the Council for

its opinion on questions affecting the medical profession. The proceedings of the coming meeting will supply several illustrations. The Government of Italy, through the Italian Ambassador here, has applied to our Government for information in reference to the professional status of Italian graduates in this country and has commended the Government to ascertain its views in reference to a system of reciprocity between the countries, in giving of which those entitled to practise in Italy might be free to practise here and vice versa. The Government has applied to the General Medical Council for its views and the answer of the Council will be watched with interest by the profession. Apart from the pleasure and duty of international amity in such matters it is obvious that we have more to gain than to lose by entertaining proposals of the sort from most foreign countries. The Government has acted similarly in respect of a Bill to amend the Medical Acts transmitted to it by the Incorporated Practitioners' Society. The recent action of the Lord President in regard to the Midwives Bill is fresh in the memory of the profession. It is probably in this way that the General Medical Council will be able to do most good in influencing legislation affecting the health of the people and the rights of medical practitioners.

We do not intend to speculate as to the subjects to which the Council will devote most of its attention. But there can be no doubt as to two or three great questions into which it should put all its power and judgment. One of these—perhaps the greatest of them—is the elevation of the standard of preliminary education. The action of the Council and of its Education Committee has already stirred the educational bodies affected and called forth some complaints of partiality and unfairness. These complaints must be investigated by competent and unprejudiced persons. But the Council cannot escape from its responsibilities in this matter. The raising of the standard of the education of medical students can only be secured by a thoroughly sound general education, and this must be carried out by the action of the General Medical Council. It is not called on to make any unreasonable demands, but it is required to fix a much higher standard than the present for entrance into the profession. Another very urgent matter calling for attention is the amendment of the present Acts are most uncertain in their operation. The Council will shortly be called upon to sanction the Medical Acts for a perfectly ineffective prosecution under the Medical Acts in Scotland where the matter to most people was as clear as daylight. Other cases point in the same direction. It is in the interest neither of the public nor of the profession that such a state of the law should exist and the General Medical Council itself is the body which should move for the amendment and that without delay. We have noticed only two subjects, either of which might occupy with advantage two days of the Council's time. But there remain the questions of medical aid associations, of the action of the Council in the HUNTERS case, penal cases of some novelty and much interest, and the very pressing question of increased disciplinary powers for the degree- and diploma-granting bodies as well as for the General Medical Council—from all of which we shall not be far wrong in prognosticating a week of arduous

work. The reports, also, of various committees will demand the attention of the Council. One of especial importance emanates from the Education Committee and deals with the use of the first of the five years of the medical curriculum and the recognition of schools as teaching institutions where chemistry, physics, and biology are taught. Upon these points a lively controversy is likely to arise.

If we remember aright M. TAINÉ, with the terse and graphic exaggeration which so often characterises the expressions of French writers, declared that a degree of heat more or less, an inclination of the soil, and racial descent, were the primary causes of our faculties and passions. Be this as it may, no one denies that the sum of all the meteorological and physical conditions which make up what we understand as the climate of any given place has a considerable influence on animal and vegetable life. Notwithstanding the remarkable power of adaptability to climate which man possesses it does not belong to every man. And it must be borne in mind that the constitutions of all of us have to accommodate themselves to the environmental conditions and not *vice versa*, for it is certain that no change will occur in these conditions in order to harmonise them with the requirements or needs of living beings. From the slight and relatively insignificant changes which ensue on the first arrival of an immigrant into a new locality and climate it is conceivably easy to trace our way up to those greater, more appreciable, and more enduring modifications in a race embraced in the term "acclimatisation." Whether a traveller freshly arrived in a new locality appreciates or not the effects of a change of climate his organism does not fail to do so, it has to accommodate itself to its new surroundings and may be said to be in a state of unstable equilibrium whilst doing so. This does not, however, imply that a hot climate must necessarily be injurious to the European and can only be overcome by some powers of resistance acquired by residence. During this physiological process of adaptation, or "seasoning" as it is often called, his system manifests an increased vulnerability or susceptibility to the diseases incidental to the conditions of a new environment; the bodily functions become exaggerated or perverted, overstepping their limits the physiological may easily become pathological, in short, the newly arrived unacclimatised resident has to submit to nature's test of the survival of the fittest. In connexion with this subject the article on The Influence of Warm Climates on the Constitution, by Dr EDWARD A. BIRCH, in "Davidson's Hygiene and Diseases of Warm Climates," is worth reading, especially in reference to the effect of these climates on the physiological functions. That residence in hot climates under the circumstances of ordinary life has an adverse effect upon Europeans cannot, we think, be doubted. Some constitutions seem to be altogether unfitted for these climates and such individuals lose their health and physical energy from the moment of their arrival. A still larger number do so sooner or later under a more protracted residence, even if they escape being attacked by one or other of the endemic or epidemic diseases incidental to such climates. Residence in tropical and sub-tropical countries usually produces a very appreciable effect

not only on the complexion but on the constitution and notably so during childhood and youth.

Thus far, however, we have mainly spoken of the effects of climate in a restricted sense—namely, on the individual unit and not on the race, but it is only on the latter that acclimatisation, as understood by naturalists and climatologists, really comes in, for one must count by generations and not simply by years for the completion of that process, because by acclimatisation we understand the adaptation of animals and plants to a climate different from their own, brought about by a slow and gradual series of changes the effects of which are of an enduring and more or less permanent character. In studying the physiological and racial changes which have taken place in order to adapt and harmonise the inhabitants of the world with the different climates in which we find them we need to have recourse to time in a geological rather than an ordinary sense, and many authorities even go so far as to doubt whether true and perfect acclimatisation ever takes place. They point to distant ages in the past in which we have evidence of the existence of the various types of the human family such as they exist in the present day and they declare that nature has herself imposed insurmountable barriers to the white man's permanent occupation of the territories occupied by black people. The degree of difference of temperature, to take one great element in the problem, may be such as not only to prejudice but to prevent the survival of a transplanted race, and to render it impossible to establish a durable colonisation.

It seems to be pretty well established that the Semitic peoples possess a power of acclimatisation or adaptability to climate superior to that enjoyed by the Aryan races, and among the latter the inhabitants of the South, the Spaniards, the Portuguese, the Maltese, and the Sicilians are superior to those of the North. Next to the Jews the Gipsies are the most cosmopolitan. The admixture of a foreign blood, too, in a remote past seems to confer a power of resistance to the prejudicial effects of climate, and half castes manage to survive in climates inimical to white men.

Climate and acclimatisation have been discussed in numerous treatises and books and have formed the subject of many papers and debates at international and other scientific congresses. It is altogether too large a question to be usefully considered here. But on a more limited scale and in the restricted sense in which people ordinarily speak of acclimatisation they mean the changes which ensue on the arrival of an immigrant into a new country, the risks to health and the diseases which he has to encounter, and the steps which he can and should take in order to minimise such risks as far as possible.

To take a case in point. The American nation have entered upon a new, and in a sense Imperial, policy which may be regarded as forming an epoch in their history. This brings them face to face with the problem of colonisation and acclimatisation—a problem which we have had to confront long ago and towards the solution of which we have ever since been slowly fighting our way by following on the lines of the best practical measures of hygiene known to us. Professor VIRCHOW, in his address at the Congress of German Naturalists and Physicians at

known as *anopheles* be alone concerned in this traffic. Major Ross, I.M.S., may be right in holding that we may eventually stamp out malaria by attacking the easily accessible puddles in which it is bred. But we have, as a matter of experience, already gone sufficiently far to have made it evident how efficacious is the application of the simple hygienic precautions adopted by England in proportion as good water, pure air, and suitable food have been supplied to soldiers serving abroad so have the deadly effects attributed to climate decreased or disappeared. Climate appears to require something superadded to it in the way of malaria or the fostering aid of sanitary neglect and improper living to develop its worst effects. As regards India, for example, the report of the Royal Commission of 1863 states that prior to 1857 the mortality rate among our troops reached 69 per 1000, whereas the report of the Sanitary Commissioner with the Government of India for 1896 records it as only 14.84 per 1000 of strength. There were, of course, many other factors which contributed to this result, besides sanitary improvement, still the figures serve to show what may be done and to indicate the directions in which steps can be taken to bring about these results.

In order to give a practical turn to our observations we may as succinctly as possible point out what should be aimed at in the case of untidying colonists or of a military expeditionary force proceeding for service in a tropical or sub-tropical country, and this we propose to do on a subsequent occasion.

"The causes of female disease distinctly traceable to the practice of continually standing in shops are so many and various that we have been compelled to take action in the matter." Thus we wrote, in 1880 and the publication by us of a black list had considerable effect in ameliorating the conditions under which certain shop-girls worked at that time. Since then something further has been done in the way of early closing to mitigate the evils of long standing in shops by affording the girls opportunity for recreation, but there are still firms, we are sorry to hear, who compel their employes to stand all day long, and our statement of nearly twenty years ago with regard to the evils of this practice remains as true to-day as it was then. At a recent meeting at St. Martin's Town Hall held under the auspices of the Early Closing Association attention was called to the State for Shop Assistants (Scotland) Bill and the action of Lord Salisbury in bringing about its rejection in the House of Lords was severely condemned. It is true, as Lord Salisbury pointed out, that the Bill was too small, relating as it did to Scotland only, but we are at a loss to understand his lordship's analogy when he says that the Bill causes the image of the housemaid to cross his mind, suggests that legislation of this kind if once permitted would have to be extended to households, and asks whether the public would be prepared to have an army of inspectors to examine every house to see that there were a sufficient number of chairs placed at stated intervals so that at each moment of extension the housemaid might sit down in comfort. Lord Salisbury's well-known caution of humour here led him astray. Domestic servants are not

Stasbourg in 1885, called attention to a sphere of research in which he alleged that neither the English nor the French had hitherto accomplished much of importance in connection with the phenomena of acclimatisation—namely, the special alterations of each organ. The time has arrived, however, when we trust this reproach will no longer be applicable to this country, for it is now fully recognised that scientific inquiry into these subjects and into the nature and origin of the malarial and sub-tropical climates must go hand in hand with practical measures of prevention. "The white man's burden" has proved a tragical one in its drain on the life of the young manhood of this country, notwithstanding the very large measure of success which has attended our sanitary efforts in this direction. The Americans having taken up their burden will, no doubt, like the practical people they are, set about their task in a practical way.

The four principal factors in the production of climate, according to BRÜCKNER, are—distance from the equator, height above the sea, and prevailing winds. The equatorial region has the most equable climate, tropical regions have much greater variations of temperature than those near the equator and have a hot and cold or dry and rainy season. The isothermal lines of mean temperature do not supply a graduated measure of the effects of temperature on animal life. So far as climate is concerned no single meteorological influence appears, however, to equal the effect of temperature upon health, and its range is of more importance than its mean. The European under a tropical climate suffers from anæmia, diseases of the digestive system, especially of the liver, from malaria, dysentery, typhoid fever, and yellow fever. It is not at all easy to say, however, how much of the excess of mortality of Europeans is simply attributable to climate heat *per se* and is consequently inevitable and not the effect of malaria, or how much of it is the direct consequence of habits of life and of the neglect of sanitary laws and of personal hygiene. Biological researches, too, in relation to health and diseases have revolutionised our views in many respects by showing that many special diseases are, either directly or indirectly, caused by germs, and investigators have nowadays to be matinalists in addition to their other qualifications. Climatic conditions probably constitute an important factor in the multiplication, development, and diffusion of microbic germs, but this is a branch of bacteriology which has hitherto been comparatively little studied. As ANOVID highly said, the *habitudes d'hygiène* of the Anglo-Saxon constitute one of the stumbling blocks to health, but by far the most important is malaria, compared with which the rest are relatively insignificant. Mr. CHAMBERLAIN was right when he said the other day that "the man who shall successfully grapple with this foe to make the tropics liveable for the white man will do more for the world and more for the British Empire than the man who adds a new province to the wide dominions of the Queen."

If mosquitoes be the sole vehicle for the conveyance of the malarial parasite to man and the particular kind

placed in the same environment as shop-girls, and arduous as their work undoubtedly is and overstrained as too many of them are by inconsiderate mistresses, and still more by inconsiderate upper servants, yet as a class we think they receive and take opportunities of occasionally sitting down.

We as medical men maintain that sitting accommodation and opportunities for the use of that accommodation are absolutely necessary for shop-girls, especially having regard to the conditions under which they pursue their daily labours. The only argument having even the semblance of legitimacy which we have heard put forward in defence of the non provision of seats is that sitting is conducive to idleness, but in this connexion such a premiss cannot be admitted, for an employee would be bound to come forward when an intending purchaser entered the shop and, more over, the fact that a girl was able to sit down would not prevent her from performing the many duties of packing and folding which might be necessary after the visit of a customer. This perhaps does not apply to the heavy departments, but here for the most part men are employed, it does, however, apply to the light or fancy departments where girls serve. Again, if the employee were allowed to sit down and rest she would be able to recuperate in some measure the loss of strength entailed by long hours and thus to do for her employer a great deal better work than she is at present able to accomplish. The very fact that in many shops she is not allowed to sit down is conducive to idleness—idleness of the worst kind—the idleness of pretending to do something whilst in reality nothing is being done, and it is noteworthy that many employers encourage this. They fondly imagine that their customers can be cheated into the belief that a great deal of business is being done if their employees are made to be seemingly always at work and goods are packed and unpacked, repacked and dusted *ad infinitum* to this end. The device is as transparent as it is ludicrous.

Can nothing be done to stop this—as we once called it without the least exaggeration or sensationalism—"cruelty to women"? The women who are most concerned dare not complain for fear of losing their situations. What, then, is the remedy? The publication of our black list was productive of good results, but the real prevention of this abuse of labour rests almost entirely with the women who deal with the firms who are cruel to their employees. There are many women, we know, who, alas, have no sympathy with other members of their sex, and who for the sake of merely passing an idle hour compel shop-girls to show them article after article while at the same time they know that their purchase will ultimately be a small one or even nothing. To these we do not appeal, but leave them to be dealt with by the humane, and larger, majority of their sex. To the true woman—the woman with feelings for her sisters, the woman of love and sympathy, the true woman in every sense of the word—we appeal for help in this matter. If such women would abstain from purchasing at shops where they see that the employees are compelled to work from morning till night without permission to rest from their labours even when opportunity occurs, we should soon see the end of a practice which ruins the health and shortens the lives of many of

our shop-girls. To such women we feel that we shall not appeal in vain, especially when we remind them that the physical vigour of the future race depends even more upon the health and strength of woman than it does upon the health and strength of man. This and the fact that on the health of many of these girls may ultimately depend that of a future generation will, we feel sure, appeal to women as a majority, and their love, their sympathy, and even their loyalty to the race to which we are all proud to belong will stimulate them to the utmost degree to put an end to this "cruelty to women."

THE report of the special committee appointed by the Pathological Society of London to consider the nomenclature of the condition sometimes described as "pseudo-tuberculosis" will be received, we think, with favour by the profession. The addition of the prefix "pseudo" to a pathological condition or a disease is to be deprecated and is sure to give rise to confusion, and the suggestions made by the committee will, it is to be hoped, render the term "pseudo-tuberculosis" superfluous and cause it to be altogether discarded.

It is, however, to another portion of the committee's report that we wish to draw special attention and that is as regards the employment of the terms "tubercle" and "tuberculous." These two words, together with another term, "tubercular," have been very loosely used, many, if not most, writers apparently considering them to be entirely synonymous. For our part we have for years past endeavoured very carefully to differentiate in the use of the adjectives "tuberculous" and "tubercular," meaning by the former the lesions caused by the disease produced by the tubercle bacillus of KOCH, and by the latter a formation presenting the physical appearance of a nodule not so caused. We especially welcome, therefore, the recommendations of the committee as expressed in their report that the word "tubercle" should no longer be used as a general anatomical term, but should be only employed as a designation of the nodular lesions produced by the tubercle bacillus. To prevent ambiguity, however, it might be still better if all lesions having the form of "tubercles" were called generally "nodules," those produced by KOCH'S bacillus being distinguished as "tuberculous nodules," and if the nodules produced by other causes were in like manner distinguished by a prefix indicative of their cause. We notice that the term "tubercular" does not appear in the report and we trust in future that its use as a synonym of "tuberculous" may be abandoned. Medical phraseology is already sufficiently copious and any redundant or ambiguous words or phrases may well be obliterated. Many committees have from time to time been appointed by various societies, some have done good work, others have delayed the issue of their reports that their suggestions have greatly lost their value owing to the lapse of time, whilst the valuable efforts of others have never been known beyond the actual members of the committee. The committee, however, to whose report we have briefly referred have done their duties promptly and well and deserve the thanks, not only of the society of which they were representatives but of the whole scientific world.

Announcements.

"No guild nimbler."

THE QUEEN'S EIGHTIETH BIRTHDAY

The Queen is a wonderful old lady. The homely phrase will not, we trust, jar upon the susceptibilities of our readers when applied to the powerful and august leader to whom so many millions owe faithful allegiance. We use it designating as expressing the tender feeling towards Her Majesty as the Mother of her People which we know to be universal in her realms and which peeps out in every formal or gorgeous celebration which her prolonged reign among us gives occasion for. "A wonderful old lady" is the affectionate expression of admiration and esteem which in the family circle is universally given to the head of that family whose age does not preclude her from rightly filling the position of head. With admiration her juniors note that years do not blunt the susceptibilities of the patriarch, that the bearded up trials and successes, joys and griefs of a long life have not deadened her sympathies to the new things the new developments, the new ideas, which were unheard of in her own youth but which now constitute so much of the lives of her grandchildren and younger descendants. The "wonderful old lady" brings to face the troubles of the hour the accumulated experiences of a lifetime and before her wisdom the troubles dispel themselves. What she approves of all her family will and worth their approbation, what she turns from will certainly be found to have its trial or unworthy side. It is in this way that her subjects are prouddest to regard Her Majesty. Her reign has been unsurpassed in its developments. With all of these she has managed to remain in close touch, appreciating that which is good in them and exercising a very judicious restraint upon that which is not. And now at 80 years of age, in complete possession of all her faculties, she spends the evening of her days in caring for her people, abating their joys, dividing their sorrow, and presenting in all events a splendid example of dignity, good sense, and loving kindness. Our Queen is a great queen and also "a wonderful old lady."

THE APPOINTMENT OF COUNTY MEDICAL OFFICERS OF HEALTH

We have on previous occasions written on the advantages of the appointment of a county medical officer of health as distinguished from a district medical officer. Many county councils, however, seem to regard a county medical officer as something to be avoided. In THE LANCET of Jan 28th we recounted how the Wiltshire County Council had decided to appoint a county medical officer while the neighbouring county of Somerset had refused to do so. We are sorry to have to chronicle the same piece of shortsightedness on the part of another county—namely, Hampshire. A quarterly meeting of the Hampshire County Council was held in Winchester Castle on May 15th when the report of the General Purposes Committee was brought up. The report stated: "Your committee are of opinion that it is inadvisable to appoint a medical officer for the county, but they consider that more attention might well be devoted to the consideration of the annual reports of the medical officers of health of the several urban and rural districts and their proposals to appoint a special sub-committee for that purpose. They find that a competent medical officer for the county could not be secured for a less salary than £500 a year exclusive of expenses." Colonel Grimston, the chairman of the committee, related a humorous story about a friend of his own, a property owner in

the north, who told him that the county had appointed a medical officer of health who had become a perfect nuisance. He (the medical officer) was an exceedingly nice man personally but his name stank in the nostrils of the county gentlemen because he was always interfering—he was obliged to make work and whenever he appeared people were afraid he was going to take action. The Hants County Council were so struck by this tale that they accepted their committee's report without discussion. We set forth the reasons why a medical officer of health for the county is a desirable official in THE LANCET of Nov 26th, 1898, and on Jan 28th, 1899, and we need not recapitulate them here except to say again that in sanitary matters, as in everything else, there must be a central head.

THE MEDICAL FACTOR IN IMPERIAL EXPANSION

THE Protectorate of British Central Africa, from its inception to its completion, is the work of two men, both of them medical missionaries, Dr David Livingstone and Dr James Stewart. It is a magnificent contribution to the great work of which the closing century will see the beginning and of which the coming century will see the development—the reclamation of the Dark Continent to its place in the evolution of humanity. Religion and medicine, not in antagonism, but going hand in hand, *viribus unitis*, must be credited with this achievement, and it is to the honour of both professions that they freely acknowledge the services which each owes to the other in the common result. In 'THE LANCET,' in commenting on the great meeting held in Glasgow for the promotion of medical missions, we dwell on this harmonious co-operation of religion and medicine and we pointed out how the British Empire, in its policy of expansion, enjoys through this co-operation an advantage shared in equal measure by no other rival. True, Cardinal Lavigerie, in his splendid work for the civilising of the Sahara, did not neglect the healing art as an instrument towards that end. But his organisation of the Christian Brothers, in its preponderance of the proselytising element, and in its preference of the military to the medical arm, was far inferior to its British counterpart, as indeed is already proved by results. The more the civilising power keeps the display of force in the background, the more its success in winning over the aborigines and in welding them into the higher social organisms which it seeks to consolidate. To impress such peoples with the superiority of the new to the traditional order the effort of the missionary is accelerated incalculably by his knowledge of Nature and her forces, by his utilisation of these to meet existing wants, above all, by his power to hereditary victims "the shade that flies in darkness" Medicine, which is simply nature study in its highest, most complex, and most refined form, represents that moral agency as its aim and impresses the savage mind with corresponding power and effect. This truth was well known to Dr Livingstone, as may be read even between the lines thoroughly grasped by Dr Stewart, after previous qualification in the arts curriculum of Edinburgh University, Stewart at this stage was attracted by Dr Livingstone's "missionary travels," and as a step towards following in his footsteps he added nature-study in its medical department to his "armamentarium." Having graduated M.D. he threw himself into missionary enterprise the peoples of East Central Africa being his first objective. The record of

placed in the same environment as shop-girls, and arduous as their work undoubtedly is and overstrained as too many of them are by inconsiderate mistresses, and still more by inconsiderate upper servants, yet as a class we think they receive and take opportunities of occasionally sitting down!

We as medical men maintain that sitting accommodation and opportunities for the use of that accommodation are absolutely necessary for shop-girls, especially having regard to the conditions under which they pursue their daily labours. The only argument having even the semblance of legitimacy which we have heard put forward in defence of the non provision of seats is that sitting is conducive to idleness, but in this connexion such a premise cannot be admitted, for an employee would be bound to come forward when an intending purchaser entered the shop and, moreover, the fact that a girl was able to sit down would not prevent her from performing the many duties of packing and folding which might be necessary after the visit of a customer. This perhaps does not apply to the heavy departments, but here for the most part men are employed, it does, however, apply to the light or fancy departments where girls serve. Again, if the employee were allowed to sit down and rest she would be able to recuperate in some measure the loss of strength entailed by long hours and thus to do for her employer a great deal better work than she is at present able to accomplish. The very fact that in many shops she is not allowed to sit down is conducive to idleness—idleness of the worst kind—the idleness of pretending to do something whilst in reality nothing is being done, and it is noteworthy that many employers encourage this. They fondly imagine that their customers can be cheated into the belief that a great deal of business is being done if their employees are made to be seemingly always at work and goods are packed and unpacked, repacked and dusted *ad infinitum* to this end. The device is as transparent as it is ludicrous.

Can nothing be done to stop this—as we once called it without the least exaggeration or sensationalism—"cruelty to women"? The women who are most concerned dare not complain for fear of losing their situations. What, then, is the remedy? The publication of our black list was productive of good results, but the real prevention of this abuse of labour rests almost entirely with the women who deal with the firms who are cruel to their employees. There are many women, we know, who, alas, have no sympathy with other members of their sex, and who for the sake of merely passing an idle hour compel shop-girls to show them article after article while at the same time they know that their purchase will ultimately be a small one or even nothing. To these we do not appeal, but leave them to be dealt with by the humane, and larger, majority of their sex. To the true woman—the woman with feelings for her sisters, the woman of love and sympathy, the true woman in every sense of the word—we appeal for help in this matter. If such women would abstain from purchasing at shops where they see that the employees are compelled to work from morning till night without permission to rest from their labours even when opportunity occurs, we should soon see the end of a practice which ruins the health and shortens the lives of many of

our shop-girls. To such women we feel that we shall not appeal in vain, especially when we remind them that the physical vigour of the future race depends even more upon the health and strength of woman than it does upon the health and strength of man. This and the fact that on the health of many of these girls may ultimately depend that of a future generation will, we feel sure, appeal to women as a majority, and their love, their sympathy, and even their loyalty to the race to which we are all proud to belong will stimulate them to the utmost degree to put an end to this "cruelty to women."

THE report of the special committee appointed by the Pathological Society of London to consider the nomenclature of the condition sometimes described as "pseudo-tuberculosis" will be received, we think, with favour by the profession. The addition of the prefix "pseudo" to a pathological condition or a disease is to be deprecated and is sure to give rise to confusion, and the suggestions made by the committee will, it is to be hoped, render the term "pseudo-tuberculosis" superfluous and cause it to be altogether discarded.

It is, however, to another portion of the committee's report that we wish to draw special attention and that is as regards the employment of the terms "tubercle" and "tuberculous." These two words, together with another term, "tubercular," have been very loosely used, many, if not most, writers apparently considering them to be entirely synonymous. For our part we have for years past endeavoured very carefully to differentiate in the use of the adjectives "tuberculous" and "tubercular," meaning by the former the lesions caused by the disease produced by the tubercle bacillus of KOCH, and by the latter a formation presenting the physical appearance of a nodule not so caused. We especially welcome, therefore, the recommendations of the committee as expressed in their report that the word "tubercle" should no longer be used as a general anatomical term, but should be only employed as a designation of the nodular lesions produced by the tubercle bacillus. To prevent ambiguity, however, it might be still better if all lesions having the form of "tubercles" were called generally "nodules," those produced by KOCH'S bacillus being distinguished as "tuberculous nodules," and if the nodules produced by other causes were in like manner distinguished by a prefix indicative of their cause. We notice that the term "tubercular" does not appear in the report and we trust in future that its use as a synonym of "tuberculous" may be abandoned. Medical phraseology is already sufficiently copious and any redundant or ambiguous words or phrases may well be obliterated. Many committees have from time to time been appointed by various societies, some have done good work, others have delayed the issue of their reports that their suggestions have greatly lost their value owing to the lapse of time, whilst the valuable efforts of others have never been known beyond the actual members of the committee. The committee, however, to whose report we have briefly referred have done their duties promptly and well and deserve the thanks, not only of the society of which they were representatives but of the whole scientific world.

the north, who told him that the county had appointed a medical officer of health who had become a perfect nuisance. He (the medical officer) was an exceedingly nice man personally but his name stank in the nostrils of the county gentlemen because he was always interfering—he was obliged to make work and whenever he appeared people were afraid he was going to take action. The Hants County Council were so struck by this tale that they accepted the committee's report without discussion. We set forth the reasons why a medical officer of health for the county is a desirable official in THE LANCET of Nov 26th, 1898, and Jan 28th, 1899, and we need not recapitulate them here except to say again that in sanitary matters, as in everything else, there must be a central head.

THE MEDICAL FACTOR IN IMPERIAL EXPANSION

THE Protectorate of British Central Africa, from its inception to its completion, is the work of two men, both of them medical missionaries, Dr David Livingstone and Dr James Stewart. It is a magnificent contribution to the great work of which the closing century has seen the beginning and of which the coming century will see the development—the reclamation of the Dark Continent to its place in the evolution of humanity. Religion and medicine, not in antagonism, but going hand in hand, *virtus unitis*, must be credited with this achievement, and it is to the honour of both professions that they freely acknowledge the services which each owes to the other in the common result. In THE LANCET, in commenting on the great meeting held in Glasgow for the promotion of medical missions, we dwell on this harmonious co-operation of religion and medicine and we pointed out how the British Empire, in its policy of expansion, enjoys through this co-operation an advantage shared in equal measure by no other rival. True, Cardinal Lavigerie, in his splendid work for the civilising of the Sahara, did not neglect the healing art as an instrument towards that end. But his organisation of the Christian Brothers, in its preponderance of the proselytising element, was far inferior to its British counterpart, as indeed it already proved by results. The more the civilising power keeps the display of force in the background and makes moral suasion its distinctive method, the more its success in winning over the aborigines and in welding them into the higher social organisms which it seeks to consolidate. To impress such peoples with the superiority of the new to the traditional order by his knowledge of Nature and her forces, by his utilisation of these to meet existing wants, above all, by his power to exorcise epidemic diseases and to avert from the hereditary victims "the shaft that flies in darkness" Medicine, which is simply nature study in its highest, most complex, and most refined form, represents that moral agency at its acme and impresses the savage mind with corresponding power and effect. This truth was well known to Dr Livingstone, as may be read even between the lines of his most purely missionary publications, and it was thoroughly grasped by Dr Stewart, "his assistant and successor." Trained for the Church, after previous qualification in the arts curriculum of Edinburgh University, Stewart at this stage was attracted by Dr Livingstone's "Missionary Travels," and as a step towards following in his footsteps he added nature-study to his medical department. Having graduated M.D. he threw himself into missionary enterprise, the peoples of East Central Africa being his first objective. The record of

"The Queen is a wonderful old lady. The homely phrase will not we trust, jar upon the susceptibilities of our readers when applied to the powerful and august leader to whom so many millions owe faithful allegiance. We use it designated as expressing the tender feeling towards Her Majesty as the Mother of her People which we know to be universal in her realms and which peeps out in every formal or gorgeous celebration which her prolonged reign among us gives occasion for. "A wonderful old lady" is the affectionate expression of admiration and esteem which in the family circle is universally given to the head of that family whose age does not preclude her from rightly filling the position of head. With admiration her juniors note that years do not blunt the susceptibility of the patriarch, that she heaped up trials and successes, joys and griefs of a long life have not deadened her sympathies to the new things the new developments, the new ideas, which were unheard of in her own youth but which now constitute so much of the lives of her grandchildren and younger descendants. The 'wonderful old lady' brings to face the troubles of the hour the accumulated experiences of a lifetime and before her wisdom the troubles dispel themselves. What she approves of all her family find worth their approbation, what she turns from will certainly be found to have its trial or unworthy side. It is in this way that her subjects are provided to regard Her Majesty. Her reign has been un surpassed in its developments. With all of these she has managed to remain in close touch, appreciating that which is good in them and exercising a very judicious restraint upon that which is not and now at 80 years of age, in complete possession of all her faculties, she spends the evening of her days in caring for her people, sharing their joys, dividing their sorrows, and presenting in all events a splendid example of dignity, good sense, and loving kindness. Our Queen is a great queen and also "a wonderful old lady."

THE QUEEN'S EIGHTIETH BIRTHDAY

Annotations.

We have on previous occasions written on the advantages of the appointment of a county medical officer of health as distinguished from a district medical officer. Many county councils, however, seem to regard a county medical officer as something to be avoided. In THE LANCET of Jan 28th we recounted how the Wiltshire County Council had decided to appoint a county medical officer while the neighbouring county of Somerset had refused to do so. We are sorry to have to chronicle the same piece of shortsightedness on the part of another county—namely Hampshire. A quarter meeting of the Hampshire County Council was held in Winchester Castle on May 15th when the report of the General Purposes Committee was brought up. The report stated: "Your committee are of opinion that it is inadvisable to appoint a medical officer for the county, but they consider that more attention might well be devoted to the consideration of the annual reports of the medical officers of health of the several urban and rural districts and they propose to appoint a special sub-committee for that purpose. They find that a competent medical officer for the county could not be secured for a less salary than £500 a year exclusive of expenses." Colonel Grimston, the chairman of the committee related a harrowing story about a friend of his own, a property owner in

THE APPOINTMENT OF COUNTY MEDICAL OFFICERS OF HEALTH

his career from 1860 onwards is one of the most interesting and inspiring of the century—an example of how far and to what altitudes the religious enthusiast reinforced by nature-study can attain. Another coadjutor in his work of establishing the East Central African Mission—"Livingstonia," as he called it from its original promoter—was Dr Robert Laws, also a graduate in medicine as well as theology, and their conjoint work, congenially reinforced, soon became the parent of other enterprises. Another Scottish Mission, another English Mission, and two German ones followed, and "the five have created the vast colony of British Central Africa and Rhodesia stretching from the Zambesi north to the Congo Free State and Lake Tanganyika." So writes a highly competent narrator of Dr Stewart's life-work in the *Scotsman* of May 18th and from the same authority we learn that the medical missionary is in the day now passing proving himself—on the lines of his predecessors—the pioneer of political, commercial, and humanitarian developments to which no other colonising power can produce anything equal or even approaching. Railway extension is soon to follow—a resource for which the Foreign Office has been petitioned by the British Central Africa Chamber of Commerce. The imagination loses itself in forecasting the outcome of this splendid example of British science, British philanthropy, and British energy all working together with missionary effort. Already we hear of "another Lovedale" where "the choice youth of the 11,000 natives under instruction in five centres are trained to be captains of labour, catechists, printers, teachers, telegraphists, and pastors of self supporting churches." It is not difficult to understand the enthusiasm which such results can arouse and maintain in the missionary explorer. Dr Stewart himself, now 68 years of age and Moderator of the Free Church General Assembly, contemplates, we understand, a return to the scenes of his humanitarian conquests, and will take with him coadjutors reinforced from the youth who are smitten with the generous contagion of his spirit. Amid the complaints echoed from every quarter of the old European state-system as to the over stocking of the professions here is a source of relief from the exhaustion of competition. The young man who as a practitioner in some industrial centre can hardly make ends meet may transfer the struggle to other and not less noble fields—fields remunerative in every sense and teeming with illustrations of the truth that nature-study in its highest form and in the power which it confers is never thrown away.

AN ACT TO REGULATE DISPENSARIES IN NEW YORK.

THE *Medical Record* of New York of May 6th devotes a leading article to praise of "a new Act to regulate the conduct of dispensaries." The abuse of these institutions seems to have corresponded very much to the abuse of the outpatient department of our hospitals and to have amounted to "a glaring scandal." By the Act all dispensaries, whether public or private, are placed under the control of the State Board of Charities. Power is given to the same body of licensing or revoking the licence of dispensaries, but this does not apply to those already incorporated. The licence in this case can only be revoked by appeal to the Supreme Court. The State Board is also charged with the duty of drawing up regulations for the conduct of the dispensaries to which the latter are required strictly to adhere. The law further enacts that any person obtaining medical relief by false pretences shall be guilty of a misdemeanour and liable to a fine of not less than 10 dollars and not more than 250 dollars. Everything will depend on the working and the application of this Act and we shall welcome all good reports on the subject by our contemporary. It is to be hoped that

those who are responsible for the management of our medical charities will take note of this new departure in the United States. We sincerely trust that reform will come in our country without an appeal to legislation. But it is high time that the committees of our dispensaries and hospitals should begin to show that voluntary action is sufficient to remedy the abuses complained of.

THE SCANDAL AT THE LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES

THE recent *démouvement* at the Liverpool Hospital for Cancer and Skin Diseases points to a very undesirable condition of affairs as existing at that institution. As some of the matters in dispute will probably be the subject of investigation in a court of law we confine our observations to facts which have already become public property. The staff of the hospital has hitherto consisted of three medical officers and three assistant medical officers, the former being Mr J D Crawford, Dr J Stopford Taylor, and Dr William Whitford. At the end of the year 1898 a sub-committee of five members of the general committee was appointed to inquire into the internal management of the hospital. The three medical officers received invitations to offer suggestions as to any improvements which they considered to be necessary for its better management and to send any specific complaints which they desired to make. Dr Taylor and Dr Whitford alleged against Mr Crawford that private patients were sent by him to the hospital for the purpose of having their medicines made up at the expense of the hospital. They also alleged that he had used the hospital in other ways for his own advantage and that he had behaved in an indecent manner to some of the nurses. Mr Crawford also made certain allegations against Dr Whitford, not of a serious nature. The sub-committee met on several occasions and finally reported that the charges made against Mr Crawford had not been proved and they recommended a revision of the medical staff. The committee thereupon called upon Dr Taylor and Dr Whitford to resign their appointments. These two gentlemen declined to accede to the request of the committee who referred the matter to the general body of the subscribers. Prior to the subscribers' meeting a general meeting of the Liverpool Medical Institution was summoned when a resolution was proposed protesting against the dismissal of Dr Taylor and Dr Whitford. After considerable discussion the previous question was moved and carried. It was felt by a considerable body of the members that the society should not pledge itself to take part in matters which were still *sub judice*. No official opinion on either side was expressed. A memorial signed by 108 practitioners in Liverpool, comprising a number of the leading members of the profession, was addressed to the subscribers setting forth the opinion of the signatories that, in the interests of justice and for the welfare of the hospital, an independent inquiry was demanded. Dr Taylor and Dr Whitford at the same time sent to the subscribers a pamphlet containing an exhaustive criticism of the sub-committee's report in which they alleged that the committee had ignored several important points of evidence. A general meeting of the subscribers was summoned for May 10th to consider the report of the committee calling for the resignations of Dr Taylor and Dr Whitford. After a heated discussion the action of the committee was sustained by 44 votes to 20. An amendment moved by Mr James Lister "that this meeting of subscribers and donors, being dissatisfied with the result of the investigation of the committee of the hospital, desire that the Lord Mayor be appealed to to appoint a committee to inquire into the charges, and that the Lord Mayor be requested to ask the committee to inquire into the matters raised in the

Mr. Lister said he had already spoken to the Lord Mayor who had expressed himself willing to undertake such a step if requested. A proportion representing 42 per cent of the subscribers present were thus dissatisfied with the report of the committee. It is also alleged that 36 individuals had qualified as governors at the minimum amount a few days before the date of the meeting in order to vote on the proceedings. Should this allegation prove to be correct the laws of this institution are in need of drastic reform. At the majority of the Liverpool charities the rule is enforced that a governor or trustee cannot vote in general meeting unless his subscription shall have been paid prior to a period of three months. The rule is obviously a wholesome one, framed for the purpose of preventing abuse. The resignations of two out of the three assistant medical officers have also been announced as well as that of the matron. The charity is clearly in an unsatisfactory condition and we hope that the subscribers will demand an independent inquiry.

A SCHOLARSHIP FOR MEDICAL RESEARCH

THE Technical Education Board of the London County Council is co-operating with the Asylums Committee in offering a valuable scholarship of £150 a year tenable for two years for students of either sex (preferably qualified practitioners) to enable them to carry on investigations into the preventable causes of insanity. The lady or gentleman appointed to the Scholarship will carry on investigations in the pathological laboratory attached to Claybury Asylum. A similar scholarship has been held during the past two years by Dr. J. O. W. Barratt, who has carried on valuable original investigations into the causes of insanity, many of which will be published in the Archives of the Pathological Laboratory of the London County Asylum, the director, Dr. F. W. Mott. Dr. Barratt has recently been appointed Pathologist at the Wakefield Asylum and the scholars should be made to the secretary of the Technical Education Board, 116, St. Martin's-lane, W.C., not later than Wednesday, June 7th.

A VACCINATION CASE

AN action of some importance to the medical officers of prisons and other public institutions has been decided in Glasgow. The case was at the instance of John Lamb Thomson against Mr. J. Devon, medical officer of Her Majesty's prison, Glasgow, claiming £500 as damages for assault alleged to have been committed on him by Mr. Devon on Dec. 28th, 1897, when Thomson was a prisoner in Dukes-street prison, Glasgow. The Sheriff Substituted before whom the case was first considered, heard a proof lasting four days and thereafter gave judgment in favour of the defender and found him entitled to expenses. The pursuer then appealed to Sheriff Principal Berry who has adhered to the decision of the Sheriff Substituted and has found the appellant liable in the expenses of the appeal. In a note Sheriff Principal Berry states that the question of liability in damages, either substantial or nominal, depends upon whether Thomson is to be held to have consented to vaccination by Mr. Devon. If he consented there was no assault, but if he did not consent there was an assault for which there would be liability in damages though the amount of the same would be for further consideration. There was an original plea by the pursuer of carelessness or negligence on the part of Mr. Devon, but that was not urged before the Sheriff Principal, and the only question was one of assault. It was contended for the pursuer that he was led to suppose that his vaccination was a part of the prison discipline and that though he might not

THE PHARMACOLOGY OF CHLORIDE OF LIME

In the *Archives de Médecine Navale* for April Dr. Paul Petit calls attention to the merits of chloride of lime as an external application in surgical, ophthalmic, and gynaecological practice and also as an injection in affections of the rectum and bladder. In the absence of the substances usually employed, or, as he thinks, preferentially, we possess in this white powder which is universally procured a remarkably efficacious and absolutely harmless antiseptic. Hitherto chloride of lime has been almost exclusively relegated to the sweetening of latrines and such like services, but it amply deserves elevation to more noble usage. In times gone by Labarraque's fluid (liquor sodæ chlorinatæ, B.P.) was largely utilised by medical men and to this day there are progressive practitioners who, nevertheless, have recourse to the old fashioned medicaments in the treatment of curial ulcers, erysipiides, throat affections with false membranes, diphtheria, and pertussis of children of lime, which is 10 times more active than the congener and does not, like it, irritate the tissues in the least, is totally ignored. According to Chamberland and Remach a solution of chloride of lime containing 77 per cent of chlorine to the litre is very energetic, acting more efficaciously on moist germs than Javel water or Labarraque's fluid, and, in fact, possessing about the same power as a 1 per cent. solution of corrosive sublimate. The antiseptic properties of chloride of lime do not depend upon the strength of the solution, being at their maximum when the chlorine exists in the above proportion, but it desired a more concentrated form may be employed without any fear of bad results as Chamberland's experiments against the removal of chemical disinfectants chloride of lime acts best when warm and should before being used be heated up to from 110° to 120° F. In conclusion Dr. Petit sums up his case as follows:—a solution of one part of chloride of lime to 120 of water is very powerfully antiseptic ten times more so than Van Swieten's liquid, and since it is neither toxic nor caustic it may be regarded as absolutely inoffensive. Moreover, chloride of lime not only cleanses but softens albuginoid matter, instead of converting it into tough coagulum. The cost being infinitesimal it may be freely used in operative surgery for disinfecting large objects such as basins and jugs, tables, &c., and also for washing floors and walls. The only objections to chloride of lime are its cleaning small and its corrosive action on metal. Washing the hands in a weak solution of muratic acid will remedy the first defect and a little attention the second incidentally. Dr. Petit remarks that premises before undergoing

acted for Mr. Devon. He, the secretary of the local Anti-Vaccination Society, acted as agent for Thomson, while the solicitor and clerk to the police department of the Glasgow Corporation. Thomson knew well enough what was at foot Mr. J. Barratt, the secretary of the local Anti-Vaccination Society, on a outside suggestion and the Sheriff Principal agreed that Substituted as very like either an advertisement or a notice. The pursuer's explanation had struck the Sheriff-shocked. The pursuer to be done, as he supposed he was about to be was going to be done, as he supposed he was about to be knowing and that it was done before he was aware of what. Mr. Devon had made no such representation to him. The pursuer, indeed stated that he was vaccinated without that the pursuer was not under the delusion that the operation was required by the rules of the prison and that had little hesitation in agreeing with the Sheriff-Substituted for assault. On the question of fact the Sheriff-Principal consent necessary to relieve the medical man from liability submission to authority on his part as distinguished from have openly objected to the operation there was merely

disinfection should be moistened because germs when moist are much less resistant than in the dry state. In this connexion the following quotations from "a whilom authority" will be of interest: "As an antiseptic, Labarraque preferred the hypochlorite of soda, on the ground that by the process of disinfection it becomes chloride of sodium, which is not a deliquescent salt, whereas the chloride of calcium generated by chloride of lime, attracts water from the atmosphere, and thereby furnishes one of the conditions (viz, moisture) necessary to the putrefactive process. Hence, in his opinion, while chloride of lime will serve equally well for mere disinfection, chloride of soda is preferable where we wish at the same time to prevent a renewal of putrefaction."

THE CARLTON HOTEL AND THE ST JAMES'S VESTRY

It may be remembered that Messrs Waring, Limited, were summoned recently by the St James's Vestry (as the local sanitary authority) for having disregarded the by laws made by the London County Council under the Public Health (London) Act, 1891. The offence consisted in fitting up the sanitary arrangements of the new Carlton Hotel in Pall Mall in such a way that nine soil pipes were placed inside instead of outside the structure. For the defence it was urged that it would be unreasonable to compel Messrs Waring to pull down half the structure—a very magnificent building which had cost nearly half a million sterling—to alter the admitted defect, and it was submitted that a small penalty would meet the case with the understanding that future proceedings should not be taken against the hotel. Mr De Rutzen adopted this view and imposed a fine of £2 with £10 10s costs. Mr Mark Judge has now written to the London County Council to say that if the St James's Vestry have endorsed the view put forward in their name before Mr De Rutzen they have made a default in doing their duty. That he is right strictly speaking no medical man we think can deny. It is bad that an enormously expensive and otherwise perfect building should be half destroyed at an immense loss of capital and labour. But it is very bad that the soil pipes should be in the wrong place. We should certainly feel bound to support the London County Council if in the dilemma they placed the interests of public health first and took steps to insist upon the observance of their by law.

A MEMORIAL STATUE TO SIR THOMAS BROWNE

"THE opinion has long been held and the feeling often publicly expressed both locally and elsewhere, that some permanent memorial of our great philosopher and eminent writer, Sir Thomas Browne, M.D., should be erected in the city of Norwich where he resided for forty six years and in which he died in 1682. During his lifetime and shortly after his decease his chief works, especially the 'Religio Medici,' 'Christian Morals,' 'Vulgar Errors,' and 'Urn Burial,' passed through many editions, the first of these through no less than 13 in England and 11 in foreign countries, and now after the lapse of more than two centuries they are again being re-edited and widely read and studied. It is not too much to say that they are regarded with ever increasing appreciation and with a recognition of the immense power and profound learning displayed in them." This passage is taken from a circular which is being disseminated by a very influential general committee in behalf of a fund to erect a statue in Norwich to the famous medical philosopher, and in another column of THE LANCET will be found a letter from Sir Peter

Eade bringing the matter prominently to the notice of our readers. The movement, to which we have already referred, is one that has our heartiest sympathy. Other men of like eminence in literature, art, and science have had their memories perpetuated in this way in the localities associated with their names, and the time has arrived when the eloquent author of the "Religio Medici" should be similarly honoured. The General Committee announce that a most suitable position for the statue has been suggested in the Haymarket, Norwich, near the site of the house in which Sir Thomas Browne resided for so many years, and the church of St. Peter Mancroft in which he was buried. Norwich is obviously the most appropriate place for the proposed statue and the first appeal for funds was made to the inhabitants of Norwich and its neighbourhood, but it is the proper desire of the committee that the memorial should not be merely a local one. Sir Thomas Browne made Norwich his home, but he was not, strictly speaking, a native of the quaint and lovely old eastern capital, for he was born in London and was educated at Winchester. His reputation, however, is world wide, not local, and as admirers of his writings are found wherever English is spoken contributions towards his statue should flow from all sources. The cost of such a statue as is proposed would vary from £800 to £1200, according to its nature, and contributions will be received by the acting honorary secretary, Mr F R Eaton, King street House, Upper King street, Norwich or at the Bank of Barclay and Co., Limited, Norwich.

SARCOMA OF THE TESTICLE

THE *American Journal of the Medical Sciences* for May contains a useful paper on this subject by Dr G M Kober based upon six cases which he had observed and upon all the cases which he could find in German and English literature reported in the last 18 years, making 114 cases in all. Injuries such as blows, contusions, and squeezes have been regarded as exciting causes, in 32 cases there was a distinct history of traumatism. In 18 cases the disease developed in a retained testicle or when the descent had been delayed, in one the retained testicle had been pressed on by a truss, in two there was a syphilitic history, in one there was a history of metastatic orchitis from mumps. As to age, 9.3 per cent of the cases occurred before the age of 10 years, none between 10 and 15 years, 5.6 per cent between 16 and 20 years, 71 per cent between 20 and 50 years, and 14 per cent after 50 years. Of 93 cases in which the seat of disease was stated the right testicle was affected in 47, the left in 41, and both testicles in five. Sarcoma, like carcinoma of the testicle, usually develops rather rapidly, but in a few cases very slowly. Out of 99 cases, the tumour was of congenital origin in five, from a few weeks to six months' duration in 28, from seven to 11 months in 14, from one to two years in 24, from two to five years in 18, of six years' duration in two, of 15 years' in two, of 16 years' in one, of 20 years' in three, of 23 years' in one and of 26 years' in one. In most cases the patient observed a gradual but painless enlargement of the testicle for an indefinite time followed by a period of a few weeks in which the tumour grew very rapidly with dull aching, sometimes lancinating, pain. The tumour retains the shape of a normal testicle and is therefore often mistaken for orchitis. It is only when the tunica albuginea is perforated that bosses appear. The tumour is usually firm at first, later it is soft and elastic, and even fluctuating. A remarkable feature is that not infrequently there is apparent quiescence and in some instances actual diminution of the tumour (from absorption of fluid). Secondary deposits in the cord are not frequent, but implication of the lumbar and iliac glands is common.

¹ The Elements of Materia Medica and Therapeutics by Jonathan Pereira, M.D. F.R.S. and L.S., London, 1849.

unusual features of a fatal case of tetanus were the trial nature of the original lesion and the unfortunate coincidence of the attack with a surgical operation undertaken for another purpose. The patient was a man, aged 26 years, who wished to enter the police force and was admitted to the infirmary to undergo operation for the radical cure of a varicocele. Although very tall and rather delicately-looking he seemed in every other respect to be perfectly healthy. The plexus was excised and the wound was sealed with collodion. On the sixth day after the operation the patient complained of pain in the neck and jaws. The wound was examined and it was found to have soundly healed without suppuration. On thorough overhauling a small, barely healed sore was discovered on the right great toe, and on closely questioning the patient he admitted that 14 days previously this had been caused by the rubbing of his boot during a long walk. The treatment consisted in large doses of chloral and injections of antitetanic serum, but the temperature, which had been normal since the operation, rose, the convulsions became more severe, and the patient died 24 hours after the first degeneration of symptoms. Bacteriological examination of the operation wound and of the sore on the toe gave a negative result.

THE SALE OF FOOD AND DRUGS BILL.

CONSIDERABLE progress has been made with this Bill by the Standing Committee on Trade, and the Bill is down for consideration in the House of Commons on June 1st, but it is doubtful whether it will obtain a hearing then on account of some important political measures which are given as orders on the paper for the same day. The amendments in the new Bill deal chiefly with invoices as warrants, the sufficiency of the analysts' certificates as evidence, the correct labelling of mixtures, and increased penalties for offences. There is no indication, however, of the appointment of a Court of Reference, but we understand that Sir Charles Cameron intends to move the adoption of some such clause. Again, the question of preservatives has yet to be decided by a Departmental Committee, so that it is doubtful whether the Bill will be ready for consideration on the date proposed.

THE LATE CAMPAIGNS IN THE SUDAN AND ON THE NORTH-WESTERN FRONTIER

The historical events connected with Khartoum and General Gordon naturally gave the late campaign prominence in the public eye, the clear and comprehensive policy of the expedition and the important political considerations involved in its successful issue, as well as the almost scientific precision with which it was carried out, afford also a sufficient explanation of the absorbing interest which it created. Public attention can only occupy itself with one subject at a time and it was altogether different from the campaign on the North Western frontier of India to the events which were taking place in the Sudan. As regards the size and nature of the undertaking, however, and the difficulties which had to be overcome the two expeditions are not to be compared with one another. Opinion was, and still is, much divided as to the political necessity or wisdom of the Indian campaign for one thing and, for another, it was much farther off from the country and its nature did not admit of any large, brilliant or conclusive engagements being fought, but the military historian of the future will not fail to record an enormous difficulty underlying such as probably no other power in the world could have successfully been put out. A supplementary gazette has recently been published which includes the names of many officers who had been omitted from the list of honours previously.

SKIAGRAPHY AND STEREOSCOPY

The diagnosis between sarcoma and orchitis is by no means easy, in both there may be history of injury, and a matter of fact many sarcomata develop after orchitis. In all doubtful cases an exploratory incision should be made. The prognosis is grave, especially in children and rapidly growing tumours. Of 113 cases operated upon there was no history of the ultimate result in 37, 23 patients died within five months from metastasis in different organs. It lived for periods ranging from seven to 12 months, five for periods of from 16 to 24 months, and two for three years, dying from secondary growths. Of the 35 remaining cases 18 patients were alive at periods of from one to 12 months after the operation, two 13 months after operation, four from 21 months to three years, two four years, three six years, one eight years, one nine years, two 10 years, and one 15 years. Butra should be at once performed without regard to the malignancy of the tumour, since Adler has reported a case to the Berlin Medical Society, in a man, aged 24 years, whom he castrated on May 11th, 1892. The tumour proved to be a cystadenoma. The patient died in September, 1899, from metastasis in the lungs of the same character and not a trace of carcinoma or sarcoma could be detected.

"DEATH FROM TIGHT BOOTS"

Mr. MACRAE DAVIDSON gave an interesting demonstration on May 15th, at the Camera Club, of some new departures in x-ray work and their application to stereoscopic vision. Two skiagrams are taken from slightly different points of view and these are combined as a stereoscopic picture by being reflected to the eye by two mirrors placed at right angles, each being at an angle of 45 degrees to the plane of the skiagram. By placing the eyes close to the line of junction of the two mirrors a stereoscopic picture is seen. Mr. Davidson also explained his method of localising foreign bodies and stated that 100 cases of foreign bodies in the eye had now been localised in this way. This method consists in taking a known point and measuring the angles to each other. The three coördinates of the foreign body are then measured by the method of the crossed threads—also Mr. Davidson's idea. Having got these data we can by subtraction decide how far to right or left of the known point the foreign body lies, also the vertical distance and the depth in the eye equal to the vertical axis. The "known point" consists of a piece of lead wire fixed by plaster to the patient's lower eyelid. For the purpose of measurement two lines at right angles are made on the plate by placing two wires over the sensitive plate.

conferred for the North Western Frontier Campaign. It will be remembered that a very large and comprehensive medical and hospital service had to be organised for that expedition, that the medical officers had very laborious and trying work, and that the results accomplished were eminently satisfactory. It was very natural, therefore, for the members of both the medical services in India to have expected that their labours would have been fully recognised, but we cannot say that such has been the case and a very general feeling prevails that the medical officers of the expedition have not received that amount of recognition to which they were justly entitled. The vast amount of responsibility and labour, which must have devolved upon the Surgeon General of Her Majesty's forces and upon the Principal Medical Officer of India, for example, does not seem to have been recognised or taken into account in the distribution of rewards and honours.

PHTHISIS ON SHIPBOARD

TRAVELLERS are indebted to a gentleman who recently made the voyage from South Africa to England for a timely and important suggestion which appeared in the pages of a contemporary. Shortly after leaving the Cape he discovered that his fellow passenger in the same cabin was advanced in phthisis. Naturally and very properly he suggested that he might be provided with a berth elsewhere, but was informed that the existing arrangement could not be altered. He was consequently obliged to sleep in the saloon. He afterwards found that two other passengers were also phthisical. Under the circumstances it is not surprising that he makes some very pertinent observations respecting the duty of shipping companies with regard to isolation and disinfection in similar cases. There cannot indeed be any question as to the danger to others which these entail. It is true that phthisis is not infectious after the same manner or in the same degree as the exanthemata. It would be unreasonable, even cruel, to refuse a sufferer from this disease that opportunity of transit over sea which perhaps affords him his only chance of recovery. But, on the other hand, we now know that the spread of tuberculous disease is largely attributable to the inhalation of particles of dried sputum distributed in the atmosphere, and it is easily conceivable that phthisical persons are not always careful about the disposal of their expectoration. Such being the existing conditions a measure of sanitary precaution is no more than necessary, and it ought, if it is to be effectual, to include the medical examination of intending passengers by the ship's surgeon, the separate accommodation of any who are phthisical, the regular use and disinfection of special spittoons, the disinfection of handkerchiefs and soiled bed linen, and a final sanitary cleansing of the cabins occupied during the voyage when it is over. A certain amount of method and some personal exertion would be needed to carry out these arrangements, but there should be little or no monetary loss to the shipping companies, while there would certainly result a gain in security and an increase of confidence on the part of the travelling public.

THE Cavendish Lecture of the West London Medical Chirurgical Society will be delivered before the society on Friday, June 16th, at 8.30 P.M., in the Town Hall, Hammer Smith, W., by Dr. William Osler, F.R.C.P. Lond., F.R.S., Professor of Medicine in Baltimore, who has taken as his subject "Cerebro-spinal Fever."

THE Committee of the Brompton Hospital for Consumption and Diseases of the Chest have received a donation of £2500 from Sir Theodore Martin, K.C.B., in order to dedicate

a ward in memory of Lady Martin, better known to the world as Helen Faucit.

THE formal opening of the International Congress for the Prevention and Cure of Tuberculosis took place in Berlin on Wednesday, May 24th. The proceedings were inaugurated at the Reichstag in the presence of the Empress of Germany.

A CRITICISM ON THE DECISION IN HUNTER v CLARE

BY JAMES WILSON, BARRISTER AT LAW

[THE great importance of the issues raised in the case of Hunter v Clare will make the following legal criticism on the recent decision of the Divisional Court interesting to our readers. It will be seen that Mr. James Wilson does not wholly commend the interpretation of the law as laid down by Mr. Justice Lawrance and Mr. Justice Channell. There is no doubt that the matter bristles with difficulty, but we hope that our readers will consider the case strictly on its merits and will not allow any prejudice either for or against the Society of Apothecaries to influence their opinion either of the action of the General Medical Council or of the justice of the decision of the Divisional Court.]

The recent decision of a Divisional Court (Lawrance and Channell, JJ.) in the case of Hunter v Clare cannot, it is submitted, be accepted as a final determination of the law in respect to the use of medical titles by duly registered practitioners under the Medical Act of 1886. The court was asked in this case to decide whether a Licentiate of the Society of Apothecaries of London, being duly registered on the Medical Register as such in accordance with the provisions of the Medical Act of 1886, could be convicted under Section 40 of the Medical Act of 1858 for styling himself a "physician."

The point being raised for the first time in respect to a Licentiate of the Apothecaries' Society registered under the 1886 Act there was no direct authority bearing on the question to guide the court. In the absence of authority judges not infrequently find safety in a narrow interpretation of the law and so it seems to have happened here. It is an elementary rule of construction that words and phrases in a statute are to be taken as used in their technical meaning if they have acquired one and in their popular meaning if they have not, with this qualification, however, that technical words in statutes dealing with matters relating to the general public are to be construed *ut loquitur vulgus*—that is, according to the common understanding and acceptance of the terms. Mr. Justice Channell narrowed down the question which the court had to decide to one of determining whether the word "physician" was used in a technical sense or in a popular sense in Section 40 of the Medical Act of 1858. "If physician there means," said the learned judge, "simply a person who is duly qualified in law to practise in physic then it seems to me this appellant is a physician within that meaning of the word, because although it was not so at one time he is now by being a Licentiate of the Society of Apothecaries entitled to practise medicine and surgery, and if the word 'physician' in Section 40 is used in a popular sense I think one would be bound to say that he is entitled to practise in physic in a popular sense at any rate. Even if there be in any sense a distinction between 'physic' and 'medicine' I do not think there is any such distinction in the popular sense. Consequently, if 'physician' in Section 40 means—I do not say 'medical practitioner' as that expression, too, has a sort of technical sense—a person who is legally entitled to act as doctor, using the word 'doctor' in the popular sense and not in the technical sense of doctor of medicine, then I think the appellant by the qualification he has got would be entitled to call himself a physician. Prior to the passing of this Act of 1858 'physician' was commonly used as applying to what was the highest grade of medical practitioners and having regard to that fact I think it was so used in this Act and if we look through the Act we find confirmation of that view. There is some confirmation of it in the fact that most of the words used

might be seen at the exhibit of the Excel British and Colonial Milk Sterilising Co., Limited, 28, Victoria-street, S.W. Here were shown sterilised milk in bottles and tins and sterilised cream. Milk prepared in concentrated form with and without sugar could not be better exemplified than in the preparations of Henri Nestlé, of 48, Cannon-street, E.C. These preparations are to be commended, since the greatest care is taken to retain the maximum proportion of milk fat. The exhibit included the infant food made by this firm which is prepared in accordance with the requirements indicated. We have dealt at some length in our columns with the process of obtaining branched milk known as Dr Gaertner's. The product was shown at the stall of the Farnham Dairy Farm, Limited, 20, Farnham-street, E.C. It is very milk so modified as to preserve the composition of human milk and every precaution is taken to ensure uniformity, soundness and healthiness of the milk so prepared. The Anglo-Swiss Milk Company, 10, Mark Lane, E.C., exhibited their well known brand of condensed milk and in addition some useful combinations of cocoa, chocolate, and coffee with milk. This brand of condensed milk may be relied upon for a maximum of cream. The composition of milk proteins is well represented in the white powder known as 'Protea'. This substance is in reality dried milk with the fat and sugar eliminated. We have already given in our analysis of cocoa a complete analysis of this product of the Protea Co., Limited, 59, Whitechapel-street, E.C. Protea contains an extract of the general constituents of all food—namely, protein, We will next pass to meat preparations. The infant food specialities shown by Mr A. Boscott of 55, Piccadilly, call for special remarks, since in most cases the preparations are preserved in glass and are therefore placed beyond the possibility of metallic contamination on whilst being satisfactorily preserved against deterioration or other objectionable changes. Clear turtle soup is thus prepared specially clarified so that any larding or dig suitable constituents are removed. The exhibit also included condensed calf's foot, jelly, &c. The exhibit of the Royal Company of 30 Farnham-street, E.C. contained a great variety of specialities including soup powder, cornflour, meat extract, meat juice, meat jelly, and various stimulants. As is well known, 'Bovril' contains not only the stimulating extracts of beef but the nutritious constituents also. 'Protea' is a powerful nutrient which is prepared by the Leong Extract of Meat Company of 9 Fenchurch-street, E.C. It is a concentrated source of beef containing everything necessary to sustain life. The exhibit of course, included the ordinary extract of beef made on the plan first proposed by the celebrated Liebig. An agreeable departure from ordinary beef preparations is 'Hippi', a pure nutrient essence made by Messrs G. Nelson Dole and Co of 14, Doughty Hill, E.C. It yields soup or excellent gravy which is nourishing as well as stimulating. The exhibit of Messrs Brand and Co., Ltd., of Mayfair W., presented a remarkably wide range of animal foods and delicacies. Foremost among these should be mentioned the essences of beef, mutton, veal and chicken, and concentrated specimens of beef tea, mutton broth, veal broth, and chicken broth. As opposed to animal food preparations may be mentioned the various preparations of Protea or from a mixture of 5 White-street, Moorfields, E.C. Preparations are thus made similar in palatability to animal foods and being of a purely vegetable origin it is probably the case that these foods would be of benefit to persons of Gouty tendency. For some purposes, 'Albion' a highly refined vegetable fat prepared by Messrs Broadbent and Co of 83 Upper Thames-street, E.C. may be advantageously substituted for butter. It is especially suitable for making pastry and does not turn rancid. Messrs G. Van Albo and Sons of 104 Wigmore-street, Cavendish square, exhibited a typical display of their foods prepared especially for diabetic dyspepsia, and in addition a similar subject was illustrated in the exhibit of Messrs Callard and Co of 65 Regent-street W. The latter including food for the diabetic, for reducing weight for the rheumatic and gouty, and for indigestion. Messrs Cox Limited, of Epsom, Surrey, showed some excellent specimens of Epsom salt, Epsom soda, and Epsom sulphate, which are highly recommended for the treatment of the leg and enables ordinary shoes to be worn. Messrs J. F. Macfarlane and Co of Edinburgh and 9 and 11, Moor Lane, E.C., who showed their Epsom salt surgical dressings, catgut ligatures, and silk sutures besides the analgesic well known in connection with this firm, and Messrs Widdesspoon and Co of 7 Epsom-street, Lincoln's Inn, who showed temperature charts. The exhibit of Messrs L. Blake, Roberts and Co

The exhibit which attracted most attention perhaps in that department or the exhibition which included surgical and hospital appliances was the apparatus illustrating radiant heat treatment by the Downings Radiant Heat Company Limited, of 24, Budge-row, Cannon-street, E.C. The electric heaters are made on the principle of the electric incandescent lamp, so that they are numerous radiators and their heat has been described as 'warm sunshine'. They may be adapted to an ordinary fireplace for domestic purposes or applied most conveniently for the local hot-air treatment of rheumatism, gout, and allied painful affections. Close by was shown the application of the electric current to the ventilation of buildings by means of the Blackman motor fan of the Blackman Ventilating Co., Ltd., 63, Fore-street, E.C. Messrs Watson and Sons of 313, High Holborn, W.C., showed a big ray tube actuated by a large Westminster machine designed by Dr Lewis Jones. A powerful induction coil was also shown in working order by Mr H. W. Cox of 11 and 28, Curzon-street, Chancery-lane. The admirable workmanship of these coils is well known, the winding and insulation of each being personally supervised. Some excellent ray photographs were on the stall. Several applications of the 'Instra' 'warmer' were shown by Messrs D. Blum and Co, of 47, Cannon-street, E.C. Thus this handy little appliance can be used for the purpose of a pocket, chest or foot warmer and even for bicycle handles and ankle straps. The following surgical instrument makers occupied a stall and a good deal of attention seemed to be paid to the new surgical instruments presented for inspection. Messrs Mayer and Meyer, of 237, Oxford-street, Messrs Evans and Wormald of 31, Stamford-street, S.E., Mr W. K. Stacy 4, Newgate-street, E.C., Messrs Southall Brothers and Bartley, Ltd., of Birmingham (including their well-known sanitary specialities), Messrs Mart, Son and Thompson, 7 to 12, Aldersgate-street, E.C., Messrs Down Brothers of 21, St. Thomas-street, S.E., the Dental Therapeutic Co of 57, Westminster-street, Portland-place W. (dental instruments and accessories). Besides these there were many exhibits of anatomical appliances, for instance, the Domes Bell Co. of 456, Strand W.C., who showed their abdominal belts and belts, corsets, the Memlee Corset and Belt Manufacturing Co of 7, Fenchurch-street, E.C., exhibiting similar appliances, Messrs Anderson, Anderson, and Anderson, Limited, of 37 Queen Victoria-street, E.C., who exhibited their germ proof clothing and water beds, Mr Thomas Holland, of 40 South Alderley-street, Grosvenor square W., who offered for inspection his improved hipster such as for flat-foot, the Sanitary Wood Wool Co., of 26, Tharner-street, Holborn-circus, who showed their absorbent and aseptic dressings, &c., the base of which is wool wool, the O'Connor Extension Co., of 2, Bloomsbury-street, who showed their appliance for the same which compensates for shortening of the leg and enables ordinary shoes to be worn. Messrs J. F. Macfarlane and Co of Edinburgh and 9 and 11, Moor Lane, E.C., who showed their Epsom salt surgical dressings, catgut ligatures, and silk sutures besides the analgesic well known in connection with this firm, and Messrs Widdesspoon and Co of 7 Epsom-street, Lincoln's Inn, who showed temperature charts. The exhibit of Messrs L. Blake, Roberts and Co

our own hands this excellent article of food has yielded. It was the only cocoa shown at the exhibition. Hor's bread, which has also been the subject of analysis in our laboratory, was also offered for inspection and trial. As is well known, the basis of the bread as well as the biscuit and flour ground wheat containing the highly nourishing 'germ'. Amongst digestive products none could be more typical or satisfactory than those prepared by Messrs Farnhill Brothers and Foster, of Snow Hill-buildings, E.C. The exhibit included some excellent preparations of 'Farnhill' and 'Farnhill' besides peptonising porters and liquors, and a preparation for the external treatment of humors, Messrs Irving, Son, and Jones of Liverpool and 63, Chancery-lane, exhibited their 'Farnhill' 'diabetic food'. It is claimed that the carbon hydrates are so modified in these preparations as to form a beneficial rather than an injurious element to the diabetic as long as carbohydrate are admitted to be present. This claim, it seems to us, must be opposed to physiological facts. The exhibit which attracted most attention perhaps in that department or the exhibition which included surgical and hospital appliances was the apparatus illustrating radiant heat treatment by the Downings Radiant Heat Company Limited, of 24, Budge-row, Cannon-street, E.C. The electric heaters are made on the principle of the electric incandescent lamp, so that they are numerous radiators and their heat has been described as 'warm sunshine'. They may be adapted to an ordinary fireplace for domestic purposes or applied most conveniently for the local hot-air treatment of rheumatism, gout, and allied painful affections. Close by was shown the application of the electric current to the ventilation of buildings by means of the Blackman motor fan of the Blackman Ventilating Co., Ltd., 63, Fore-street, E.C. Messrs Watson and Sons of 313, High Holborn, W.C., showed a big ray tube actuated by a large Westminster machine designed by Dr Lewis Jones. A powerful induction coil was also shown in working order by Mr H. W. Cox of 11 and 28, Curzon-street, Chancery-lane. The admirable workmanship of these coils is well known, the winding and insulation of each being personally supervised. Some excellent ray photographs were on the stall. Several applications of the 'Instra' 'warmer' were shown by Messrs D. Blum and Co, of 47, Cannon-street, E.C. Thus this handy little appliance can be used for the purpose of a pocket, chest or foot warmer and even for bicycle handles and ankle straps. The following surgical instrument makers occupied a stall and a good deal of attention seemed to be paid to the new surgical instruments presented for inspection. Messrs Mayer and Meyer, of 237, Oxford-street, Messrs Evans and Wormald of 31, Stamford-street, S.E., Mr W. K. Stacy 4, Newgate-street, E.C., Messrs Southall Brothers and Bartley, Ltd., of Birmingham (including their well-known sanitary specialities), Messrs Mart, Son and Thompson, 7 to 12, Aldersgate-street, E.C., Messrs Down Brothers of 21, St. Thomas-street, S.E., the Dental Therapeutic Co of 57, Westminster-street, Portland-place W. (dental instruments and accessories). Besides these there were many exhibits of anatomical appliances, for instance, the Domes Bell Co. of 456, Strand W.C., who showed their abdominal belts and belts, corsets, the Memlee Corset and Belt Manufacturing Co of 7, Fenchurch-street, E.C., exhibiting similar appliances, Messrs Anderson, Anderson, and Anderson, Limited, of 37 Queen Victoria-street, E.C., who exhibited their germ proof clothing and water beds, Mr Thomas Holland, of 40 South Alderley-street, Grosvenor square W., who offered for inspection his improved hipster such as for flat-foot, the Sanitary Wood Wool Co., of 26, Tharner-street, Holborn-circus, who showed their absorbent and aseptic dressings, &c., the base of which is wool wool, the O'Connor Extension Co., of 2, Bloomsbury-street, who showed their appliance for the same which compensates for shortening of the leg and enables ordinary shoes to be worn. Messrs J. F. Macfarlane and Co of Edinburgh and 9 and 11, Moor Lane, E.C., who showed their Epsom salt surgical dressings, catgut ligatures, and silk sutures besides the analgesic well known in connection with this firm, and Messrs Widdesspoon and Co of 7 Epsom-street, Lincoln's Inn, who showed temperature charts. The exhibit of Messrs L. Blake, Roberts and Co

might be seen at the exhibit of the Excel British and Colonial Milk Sterilising Co., Limited, 28, Victoria-street, S.W. Here were shown sterilised milk in bottles and tins and sterilised cream. Milk prepared in concentrated form with and without sugar could not be better exemplified than in the preparations of Henri Nestlé, of 48, Cannon-street, E.C. These preparations are to be commended, since the greatest care is taken to retain the maximum proportion of milk fat. Preparations are thus made similar in palatability to animal foods and being of a purely vegetable origin it is probably the case that these foods would be of benefit to persons of Gouty tendency. For some purposes, 'Albion' a highly refined vegetable fat prepared by Messrs Broadbent and Co of 83 Upper Thames-street, E.C. may be advantageously substituted for butter. It is especially suitable for making pastry and does not turn rancid. Messrs G. Van Albo and Sons of 104 Wigmore-street, Cavendish square, exhibited a typical display of their foods prepared especially for diabetic dyspepsia, and in addition a similar subject was illustrated in the exhibit of Messrs Callard and Co of 65 Regent-street W. The latter including food for the diabetic, for reducing weight for the rheumatic and gouty, and for indigestion. Messrs Cox Limited, of Epsom, Surrey, showed some excellent specimens of Epsom salt, Epsom soda, and Epsom sulphate, which are highly recommended for the treatment of the leg and enables ordinary shoes to be worn. Messrs J. F. Macfarlane and Co of Edinburgh and 9 and 11, Moor Lane, E.C., who showed their Epsom salt surgical dressings, catgut ligatures, and silk sutures besides the analgesic well known in connection with this firm, and Messrs Widdesspoon and Co of 7 Epsom-street, Lincoln's Inn, who showed temperature charts. The exhibit of Messrs L. Blake, Roberts and Co

flowered in view of the results of analysis which in

Co., of Stratford, was interesting in showing what has been done by the application of sulphur dioxide in small pox epidemics, bubonic plague, and cholera. The gas is supplied liquefied in sealed tins or on a larger scale in copper cylinders. Besides sulphurous acid a fluid preparation of phenol was shown, known as "Lozar," wood fibre being used to absorb lozar in affording a disinfectant powder. The Amiral Soap Co. of 3, Throgmorton avenue, E.C., exhibited specimens of their soap. We have already dealt with this soap in our analytical columns. The exhibit of the Sanitas Co. of Three Colts Lane, Bethnal green, E., comprised a very great number of sanitary preparations, the basis of which is the agreeable and efficient "Sanitas" Pasteur filters and the Equifex disinfecting apparatus were illustrated in the exhibit of Messrs J. Defries and Sons, Limited, of 147, Houndsditch. Messrs Newton Chambers and Co. of Sheffield and 331, Gray's inn road, W.O., exhibited numerous preparations of the non-poisonous disinfectant "Izal." The Wade Disinfectant Syndicate of 62, Nine elms lane, S.W., showed an ingenious automatic disinfecter which flushes, deodorises, and disinfects automatically by one and the same operation. At the stall of the Berkefeld Filter Co., Limited, of 121, Oxford street, W., the Berkefeld filter was shown in working condition. The advantages of this filter are that while it is rapid in action it yields water entirely free from germs—that is sterile. The Jeyes Sanitary Compounds Co., Limited, of 64, Cannon street, E.C., exhibited their disinfectants of the type which forms a milky fluid with water of which this company were, we believe, the pioneers. "Creolin," their speciality, was shown in several forms. In addition to the perfectly pure product inseparable from the name of Messrs Price—namely, glycerine—and its combinations with malt and various drugs the Price's Patent Candle Co. (York road, Battersea) exhibited several medicated soaps for surgical purposes. Besides these there were also sanitary soaps. The space on the stall of Fleming's Oil and Chemical Company of 101, Leadenhall street, E.C., was occupied chiefly by their moth preventive specialities, besides some disinfectants and tooth powder and sanitary preparations for the bath. "Eucryl" fluid disinfectant is a preparation with which we have already dealt in our analytical columns. Together with carbolic acid and phenophorms this preparation was shown by Messrs Major and Co., Limited, of Soulecoates, Hull.

The Kronthal Co. of 53, Berners street had a very tastefully arranged stall near to the entrance. It was the largest display devoted to natural table waters and indeed the largest exhibit in the hall. Three kinds of Kronthal water were shown derived from three distinct springs. The first is a natural table water (blue label), the second a highly mineralised water said to be useful as a diuretic (red label), and the third contains iron (green label) in a permanent form and in the ferrous condition, so that it is probably of value in anæmia and chlorosis. These waters have already been examined in THE LANCET Laboratory, and we were able to report the high condition of purity of Kronthal water and of the presence of mineral constituents which make them wholesome for table and other purposes. Purgative mineral waters were exemplified in the exhibit of Messrs Ingram and Royle of 26, Upper Thames street. Carlsbad and Hunyadi Janos water serve as types. In addition to these the natural mineral waters of Vichy (in bottle) were shown, while Vichy salts and pastilles formed part of the exhibit. We have dealt quite recently in our analytical columns with the chemistry of Esvach water which contains the sulphates of sodium and magnesium but which apparently is not a natural mineral water although the active ingredients are in suitable proportion for aperient purposes. The specimens were shown by Messrs Davy, Hill, Son, Yates, and Hicks of 64, Park street, Southwark. "Sparklets" are now well known. By this system the aeration at home of any liquid is an easy possibility. We have commended the system especially as it is easily applicable to the extemporaneous preparation of aerated milk or other liquids for use by invalids. This ingenious method of aerating liquids is being developed by Aerators, Ltd., of 89, Broad street-avenue. Under this section we may include, lastly, the lime juice cordial known as Stower's and exhibited by Messrs Alexander Riddle and Co. of 36 and 38, Commercial street, E. As we have shown in our analytical columns this lime juice is a perfectly pure preparation

in which the characters of the fresh fruit in regard to aroma and fragrance are retained.

A feature of the exhibition was the occurrence here and there of book stalls on which were placed some recent additions to the literature of medicine, and several visitors found pleasure and profit in glancing through the books thus offered for inspection. Amongst those thus exhibiting were the following—Rebman, Limited, of 129, Shaftesbury-avenue, Cambridge circus, W.O. (these publishers announce specially that arrangements have been completed for the publication in English of "Lehmann's Medicinische Handatlasen"), Messrs John Bale, Sons, and Danielsson, Limited, 83-89, Great Titchfield street, Oxford street, W., and The Scientific Press, Limited, of 28 and 29, Southampton street, Strand.

BACTERIOLOGY IN TRINIDAD

WE have received a copy of the Trinidad *Mirror* which contains an account of Professor Crookshank's visit to the Colonial Hospital of Trinidad and the remarks made by him on that occasion. After saying that nothing had given him greater pleasure during his visit to the West Indies than an inspection of the Colonial Hospital, Professor Crookshank praised its administration and made several important criticisms and suggestions. We will quote these remarks *verbatim*.

There is evidence on all sides of capable administration and of a thoroughly efficient and zealous medical and surgical staff. Every attention is given as far as possible to carrying out Listerian principles. The ventilation of the wards is admirable and the attention to general sanitation is satisfactory. Nevertheless there is room for improvement. I would draw attention to the proximity of the ward for special obstetrical operations to the room used for the sanitary service of the general wards. I would also urge the need for more complete classification of the patients and that admission should not be given to cases of leprosy and to other cases (which need not be specifically mentioned here) which are quite unsuitable for admission to the wards of a general hospital. Lastly I would point out the splendid opportunities which exist for the investigation of the cause and prevention of tropical diseases, a matter which is receiving at home the attention of the Colonial Secretary of State and of the general public. Such work is of the greatest possible importance to our colonies and indirectly to the mother country. Great efforts are being made in England to train medical men (for service in the colonies) in the modern treatment and prevention of tropical diseases. In England there are opportunities for studying imported cases of tropical diseases and a training can be given in bacteriological methods. Where, however as in Trinidad, there is a large colonial hospital that is obviously the best place in which the investigation of tropical diseases can be carried on. The appointment of a medical officer who has devoted his time, and is prepared to continue to give up his time, to preventive medicine and bacteriological research in Trinidad, is a question which it is hoped will receive the immediate attention of the Colonial Government and the unanimous support of an enlightened and progressive public.

The suggestions made with a view of promoting bacteriological research and better sanitation in Port of Spain were also brought to the notice of his Excellency the Governor of Trinidad in a memorandum on the subject submitted by Professor Crookshank. Referring to the material for investigation at the Colonial Hospital, Professor Crookshank pointed out how much still remained to be done in investigating the nature of malaria, and that in the case of yaws and many other tropical diseases there was an open field for research. Professor Crookshank then put the case very strongly in support of his suggestion for the appointment of a medical officer of health and the equipment of a small laboratory. "The general practitioner in the colony, if he is to keep up with modern practice, must be able to have doubtful cases of diphtheria, malaria, typhoid fever, &c., bacteriologically examined, and he must be able to apply the antitoxin treatment. The veterinary surgeon is fighting without the modern weapons of defence if he is unable to examine milk for tubercle bacilli, or to test horses for glanders by the use of mallein, or to test cows for tuberculosis by means of tuberculin. The absence of any facilities for scientific research at the hospital, the demands of the general medical practitioners and of the veterinary surgeons in the colony, point to the need for a bacteriological laboratory either at the hospital or as an extension of the existing government laboratory. The question of the appointment of a colonial bacteriologist is one to which I would earnestly draw the attention of your Excellency. I hope that before long the colonial government may see its way to combining the work of a medical officer of health for Port of Spain with the duties of colonial bacteriologist." After appealing for

“sweeping reforms in the sanitation of Port of Spain, Professor Crookes expressed the opinion that they could be effected by the appointment of an officer holding ‘‘the degree and diplomas of M.D. and P.H. Such a specially trained officer should be responsible, if I might venture to say so, directly to your Excellency. He must have ‘‘responsibility and he must have control.’’

In the best interests of Trinidad we trust that we may bear that the suggestions have been carried out both as regards improving the sanitation of Port of Spain and promoting the study of tropical diseases

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6700 births and 3842 deaths were registered during the week ending Saturday, May 20th. The annual rate of mortality in these towns, which had been 16.5 and 17.7 per 1000 in the two preceding weeks, declined again last week to 17.6. In London the rate was 16.3 per 1000, while it averaged 18.4 in the 32 provincial towns. The lowest rates in these towns were 8.8 in Croydon, 13.6 in Huddersfield, 13.8 in Bristol, and 13.9 in Portsmouth. The highest rates were 21.7 in Wolverhampton, 23.8 in Plymouth, 23.9 in Norwich and in Liverpool, and 24.6 in Manchester. The 3842 deaths included 354 which were referred to the principal zymotic diseases, against 339 and 365 in the two preceding weeks, of these, 109 resulted from measles, 95 from whooping-cough, 69 from diphtheria, 31 from diarrhoea, 29 from scarlet fever, 20 from ‘‘fever,’’ (probably enteric) and one from small pox. No death from any of these diseases was recorded last week in Croydon, Wolverhampton, or Halifax, in the other towns they caused the lowest death rates in Preston, Bristol, and Birkenhead, and the highest rates in Bedford, Blackburn, Burnley, Leicester, and Swansea. The greatest mortality from measles occurred in Nottingham and Manchester, from scarlet fever in Norwich and Burnley, and from whooping cough in Plymouth, Cardiff, Blackburn, Burnley, Huddersfield, and Gateshead. The mortality from ‘‘fever,’’ showed no marked excess in any of the large towns. 39 deaths from diphtheria included 24 in London, nine in Leicester, seven in Sheffield, six in Swansea, five in Bedford, and three in Leeds. One fatal case of small pox was registered in Hull, but not one in London or in any other of the 33 large towns, and one small pox patient was under treatment last week in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2161, against 2131, 2139, and 2210 on the three preceding Saturdays, 211 new cases were admitted during the week, against 226, 219, and 1259 in the three preceding weeks, were again 257 last week and 41 in the two preceding weeks, which had been 251 and 257 in the two preceding weeks, referred to diseases of the respiratory organs in London, which had been 251 and 257 in the two preceding weeks, against 226, 219, and 1259 in the three preceding weeks. The deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Leeds, Newcastle-upon-Tyne, and in 12 other smaller towns. The largest proportions of uncertified deaths were registered in Liverpool, Preston, Halifax, and Gateshead.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 18.5 per 1000 in each of the two preceding weeks, rose to 19.0 during the week ending May 20th and was 1.4 per 1000 above the mean rate during the eight Scotch towns in the 33 large English towns. The rates in the eight Scotch towns ranged from 10.2 in Greenock and 12.8 in Paisley to 20.5 in Glasgow and 22.2 in Leith. The 581 deaths in these towns included 21 which were referred to measles, 12 to whooping cough, nine to diarrhoea, eight to scarlet fever, five to diphtheria, and five to ‘‘fever.’’ In all, 60 deaths resulted from these principal zymotic diseases against 52 and 53 in the two preceding weeks. These 60 deaths were equal to an annual rate of 2.0 per 1000, which was 0.4 above the mean rate last week from the same diseases in the 33 large English towns. The total cases of measles, which had been 13 and 18 and 27 in the two preceding weeks, declined again to 21.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

The following appointments are announced—Staff Surgeons J. L. Thomas to the *Edinburgh* and R. Hardie to the *Albatross*. Surgeons E. D. Macnamara to the *Endymion*, G. Taylor to the *Albatross*, W. J. Bearblock to the *Cambridge*, G. E. Duncan to the *Renown*, and G. Borell to the *Pemroke*.

The under mentioned gentlemen, who competed on May 8th and following days at the Examination Hall, Victoria Embankment for appointment as surgeons in the Royal Navy, have been granted commissions and are appointed to the *Duke of Wellington*, additional for Haslar Hospital.

The death-rate in Dublin which had been 24.8 and 26.7 in the two preceding weeks further rose again to 26.8 during the week ending May 20th. During the four weeks the rate of mortality in the city has averaged 27.0 per 1000, the rate during the same period being 16.4 in London and 17.8 in Edinburgh. The 180 deaths registered in Dublin last week included 23 of infants under one year of age and 45 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Four hundred and five deaths from violence were registered, and 76 or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent, of the deaths in the city last week were not certified.

HEALTH OF DUBLIN

The death-rate in Dublin which had been 24.8 and 26.7 in the two preceding weeks further rose again to 26.8 during the week ending May 20th. During the four weeks the rate of mortality in the city has averaged 27.0 per 1000, the rate during the same period being 16.4 in London and 17.8 in Edinburgh. The 180 deaths registered in Dublin last week included 23 of infants under one year of age and 45 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Four hundred and five deaths from violence were registered, and 76 or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent, of the deaths in the city last week were not certified.

Surgeon General Harvey, Director General, Indian Medical Service, takes three months' leave in the middle of May. Surgeon General Spencer, Principal Medical Officer, Punjab, and

officials. Whilst on leave Surgeon General Harvey will take the opportunity of visiting the Pasteur Institute at Paris and also Amsterdam in connexion with sewage questions. The retirement of the following officers has been sanctioned: Lieutenant-Colonels D Martin, I M S, and O Mallins, I M S, 1st Hyderabad Lancers, Major Young, I M S, Civil Surgeon, Umballa, and Lieutenant Greig, I M S, 27th Madras Infantry. The services of Captain Waters, I M S, are lent to Bengal, and those of Captain Lane, I M S, to the Punjab, for employment in the Jail Department. Captain Statham, R A M C, is detailed for plague duty. The services of Lieutenant-Colonel J S Wilkins, D S O, I M S, are replaced at the disposal of the Government of India from May 1st, 1899, on relinquishing charge of the duties of Special Medical Officer for Plague Operations, Bombay. Major Thorold, I M S, has taken over charge of the office of Sanitary Commissioner in the North-West Provinces and Oudh from Colonel Thomson, I M S.

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Lieutenant-Colonel C A Patten, having resigned his appointment in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS

Royal Engineers (Volunteers) 1st Hampshire Surgeon Lieutenant J Kyffin to be Surgeon Captain. 2nd Lancashire (the St Helens) Surgeon Lieutenant-Colonel E F Hall resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle* 2nd Volunteer Battalion the Royal Fusiliers (City of London Regiment) Reginald Courtenay Gayer to be Surgeon Lieutenant. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment Surgeon Lieutenant J M Phillips resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry Surgeon Lieutenant J A Wilson to be Surgeon Captain.

VOLUNTEER INFANTRY BRIGADE

South Wales Surgeon Lieutenant-Colonel P E Hill, 1st Volunteer Battalion the South Wales Borderers, to be Brigade Surgeon-Lieutenant-Colonel, on appointment as Senior Medical Officer to the brigade.

THE ROYAL MILITARY TOURNAMENT.

If any plea were necessary for the continuance of the annual display at the Agricultural Hall, Islington, the fact that the funds of the military charities are each year greatly augmented through its aid would amply suffice. But there are other and even better reasons which justify the holding of the Tournament. Not the least of these is the stimulus which it gives to recruiting, and so convinced are the authorities of this that should the present show prove successful—of which we presume there can be no doubt—it is proposed to repeat the same exhibition at Manchester almost directly. Another way in which the Tournament does an immense amount of good is by educating the public in things which pertain to military life and warfare.

On Wednesday, May 24th, the eve of the actual opening to the public, a full dress rehearsal and private view were given before the Press, the committee and members of the Tournament, and others. The first item on the programme, the naval display by seamen from H.M.S. *Excellent*, was highly appreciated by all who witnessed it and illustrated the ability and smartness of those who belong to our first line of defence. The musical ride by the G Battery of the Royal Horse Artillery was something more than a spectacular display and showed to great advantage the cleverness of the Royal Artillery drivers, while the cavalry display by the 6th Dragoon Guards (Carabiniers) and New South Wales Lancers was excellent. Both these exhibitions have a distinct educative value. It often happens that our army when engaged abroad is severely criticised by the public at home because of the ill results following upon what appears to have been some act of indiscretion. If those who judge so severely knew their subject it would often be obvious to them that what they term an act of indiscretion was not only excusable but absolutely inevitable by reason of the difficulties under which real war is conducted. And this is a point which a visit to the Tournament

will make clear to the arm-chair critic. The cavalry display as presented at the Tournament brings this out very unmistakably and teaches a lesson that all should know who desire to sit in judgment upon our troops or their leaders.

The *pièce de résistance* of the show is, of course, the pageant which this year is entitled "Warriors of Britain" and is typical of the gradual evolution of the British army from the time of the Wars of the Roses to the present day. Under the direction of Mr. Clarkson, the well known costumer and perruquier, the details of the dresses have been made accurate in even the smallest details and the spectacle is quite equal to any of previous years. The gymnastic display by non-commissioned officers under instruction at Aldershot, though not so showy as other items on the programme, shows well the excellence of the physical training which our soldiers undergo. The musical double-ride is pretty and effective and the combined display—the storming of Passer Sala—brings the performance to a close.

The sanitary arrangements of the hall are much the same as they were last year and indeed under the direction of the various officers who have been in medical charge of the Tournament little further can be done in a hall which is not peculiarly adapted for military displays. Major H E R. James, R A M C, is the Principal Medical Officer this year and he is assisted by Surgeon Major W R Crooke Lawless of the Coldstream Guards. Veterinary-Major R Rowe, A V D, is the Principal Veterinary Officer.

ENTERIC FEVER IN QUETTA

As our readers are already aware enteric fever was very prevalent and fatal in the garrison of Quetta last year. It appears that, owing to changes in the head quarter staff at Bombay, some delay has arisen in giving effect to the sanitary recommendations submitted by a committee appointed to inquire into and to report upon the subject. According to the *Times of India* of May 6th Major General Sir William Galbraith has proceeded to Simla for the purpose of urging on the Commander in Chief the necessity of the measures proposed for minimising the risk of enteric fever in the Quetta garrison. Between August and December, 1898 the deaths from enteric fever in that garrison aggregated 75 rank and file, one officer, and about a dozen women and children, and unless the main recommendations of the scheme submitted are immediately taken in hand the enteric fever season will soon occur again, the prospect of which is something too alarming to calmly contemplate.

THE PUNJAB

Anti plague inoculations have become very popular in the Jullundur district where over 4000 people in the infected area have submitted themselves to the process. The inhabitants of all the villages, such as Malpur, Garoha, and Bahara, have been inoculated.

We hear that Professor A E Wright of the Army Medical School, Netley, has at length succeeded in convincing the War Office authorities of the advisability of allowing inoculation against enteric fever to be introduced into the army. We hear that all soldiers are to be offered this benefit at no distant date. We believe that the outbreak of typhoid fever in South Africa and the immunity enjoyed by the men of the Royal Army Medical Corps who were inoculated before going to Egypt have been potent factors in bringing about this desirable ruling.

Mr Norman Hay Forbes, F R S Edin, has been appointed a Member of the Royal Company of Archers, Her Majesty's Body Guard for Scotland.

PRESENTATIONS TO MEDICAL MEN—On May 14th, at the Queen's Walk School, Nottingham, on the occasion of the presentation of certificates to the successful members of the Midland Railway Ambulance Corps, Mr J F Blurton, M B Durh, was the recipient of a small dressing-case as a token of the esteem in which he is held by the members of the corps. On the conclusion last week at Leatherhead of the course of 12 lectures on first aid to the injured in connexion with the St John Ambulance Association, and a series of six lectures on nursing open to women, the honorary secretary, Mrs Davis, on behalf of those attending, presented Mr James Dunbar Brunton, M B Edin, with a silver inkstand, appropriately inscribed, as a mark of appreciation of his gratuitous services.

Correspondence.

"And aliter potest."

MEMORIAL STATUE TO SIR THOMAS BROWNE, M.D.

TO THE EDITOR OF THE LANCET

SIR—The committee begs permission to appeal through your columns for the support of the medical profession to the above memorial Sir Thomas Browne in his day occupied the highest position in his profession and is consequently one of the greatest and most eminent of our English writers and philanthropers. Yet he stands almost alone amongst these as having no permanent public memorial. The movement for a statue of him in Norwich where he resided for 45 years and where he is buried, has received most influential support both medical and general, and it now includes that of the Royal College of Physicians of London and of its President. The sum of about £400 has so far been subscribed and further contributions are now solicited towards the estimated £1000 or £1200 required. Donations to the fund will be gladly received by either of the honorary secretaries, Dr Bessy or Mr Charles Williams of Norwich, or by the acting secretary Mr F. R. Eaton, King Street, Norwich.

I am, Sir, yours faithfully,
PETER HADGE
Chairman of Committee.

May 14th 1898.

PERSONATION BY "QUALIFIED"

TO THE EDITOR OF THE LANCET

SIR—Will you allow me space to caution medical practitioners against employing alleged qualified assistants and those seeking employment can produce certificates of registration from the General Medical Council and diplomas unqualified men taking and using the names of duly qualified. There are cases of undoubted personation in existence now—

practising without, I need hardly say, the knowledge and consent of the latter. I have just come across such a case, the third within a short space of time and I trust that steps may be taken to prosecute the offender.

I am, Sir, yours faithfully,
A G BAYLIS
General Secretary of the Medical Defence Union.

THE OPEN-AIR TREATMENT OF PHTHISIS IN VICTORIA.

TO THE EDITOR OF THE LANCET

SIR,—In an abstract from Dr McAdam's presidential address at the annual meeting of the Victorian Branch of the British Medical Association which appeared in THE LANCET of Feb 11th is the following sentence: "That while the Victorian climate was second to none in the facilities it afforded for taking advantage of the full benefit of the open air treatment, yet there was in the colony no institution in which any attempt was made to carry it out in its completeness." Now so far from this being the case we have in Victoria two buildings known conjointly as the Victorian Sanatorium for Consumption—one on the dry plains for winter and a mountain retreat for the hot months. Altogether there are 51 beds which are under one management and are generally full. It is difficult to know what Dr McAdam means by the open-air treatment "in its completeness," for even in Germany, the cradle of the system, the treatment varies in different sanatoria. Our institution is carried on medically and recently visited by myself. In another part of the colony there is in connection with the Asylum Hospital for Insane an accommodation for 50 incurable cases. This institution works in a friendly way with the Victorian Sanatorium and patients are frequently interchanged. Can over a million I think that as far as accommodation for convalescing that the population of our colony is only a little removed from that of our countrymen.

On the following day at 1 P.M. a native of Bradwell, aged 19 years was admitted to the workhouse infirmary suffering from an injury to the left shoulder received at the same time as the injury to the previous patient had been received. The only should suffer and each receive exactly the same injury—viz, a dislocation on the same side and of the same variety. The accuracy of the patients' statements was touched for by the gentleman who brought them both to the workhouse. I am, Sir, yours faithfully,
HENRY J. PRICE, F.R.C.S. Eng.
London, Essex, May 25th, 1899.

COINCIDENCES IN MEDICAL PRACTICE

TO THE EDITOR OF THE LANCET

SIR—In THE LANCET of May 13th you comment on this point under the heading "Coincidences in Hospital Practice, the amputation being suggested by articles on two rare forms of hernia and two cases of diabetes which had come under observation at the London Hospital within a very short space of time. As you remark, cases such as these are by no means uncommon in hospital practice, but they are far less frequently seen in private practice, and it is this fact of "coincidence" alone and not the nature of the injury sustained which induces me to place on record the following singular experience.

About noon on Sunday, April 30th 1899, a man from Tilgham (a village 10 miles away), aged 63 years, was admitted to the Maldon Workhouse Infirmary under the care of my partner Mr Thomas Tomlinson, the medical officer, suffering from an injury to the left shoulder. He related that he was at Bradwell, a village near Tilgham, on the previous Thursday evening April 27th, and while holding a horse harnessed to a trap the animal reared, hitting him suddenly from the ground by the left arm. A medical man found that the patient had sustained a dislocation of the humerus, but he could not reduce it at the time or at a second attempt made on April 28th. The patient was therefore sent to the workhouse infirmary. We found the injury to be of the subglenoid variety, and under anaesthetic reduction was effected. The patient returned to his home on the same afternoon.

On the following day at 1 P.M. a native of Bradwell, aged 19 years was admitted to the workhouse infirmary suffering from an injury to the left shoulder received at the same time as the injury to the previous patient had been received. The only should suffer and each receive exactly the same injury—viz, a dislocation on the same side and of the same variety. The accuracy of the patients' statements was touched for by the gentleman who brought them both to the workhouse. I am, Sir, yours faithfully,
HENRY J. PRICE, F.R.C.S. Eng.
London, Essex, May 25th, 1899.

"FEES TO MEDICAL WITNESSES AT ASSIZES AND SESSIONS"

TO THE EDITOR OF THE LANCET

SIR,—Let me thank you for once more bringing this matter to the front. I wonder how many medical men will have the courage to act upon the suggestion which you throw out in the last paragraph of the leading article under the above heading in THE LANCET of May 6th. I do not object to the medical men being refusing to make the sacrifices entailed by accepting police and assize court work. They do it though with the knowledge that the police surgeon is not quite so free as themselves to refuse all the silly cases. The matter of the rape which you allude to seems like one that happened here a month ago when for more than two hours the police tried to induce a medical man to examine an unfortunate child, 10 years old, who was said to have been criminally assaulted. It seems that it will take a few scandalous cases of that kind to bring the Home Secretary to understand that we are in earnest. I would suggest that all medical men should communicate with their respective Members of Parliament with a view to bringing some pressure to bear upon the Home Office.

I am, Sir, yours faithfully,
J. CHERRYELL.
Maiden May 12th, 1898.

Honorary Medical Examiner Victorian Sanatorium,
DOUGLAS TURNER, M.R.C.P. Lond.,
April 26th, 1899.

I am, Sir, yours faithfully,
Dr Douglas Turner, M.R.C.P. Lond.,
Honorary Medical Examiner Victorian Sanatorium,
April 26th, 1899.

officiates. Whilst on leave Surgeon General Harvey will take the opportunity of visiting the Pasteur Institute at Paris and also Amsterdam in connexion with sewage questions. The retirement of the following officers has been sanctioned: Lieutenant Colonels D Martin, I M S, and O Malins, I M S, 1st Hyderabad Lancers; Major Young, I M S, Civil Surgeon, Umballa, and Lieutenant Greig, I M S, 27th Madras Infantry. The services of Captain Waters, I M S, are lent to Bengal, and those of Captain Lane, I M S, to the Punjab, for employment in the Jail Department. Captain Statham, R A M C, is detailed for plague duty. The services of Lieutenant-Colonel J S Wilkins, D S O, I M S, are replaced at the disposal of the Government of India from May 1st, 1899, on relinquishing charge of the duties of Special Medical Officer for Plague Operations, Bombay. Major Thorold I M S, has taken over charge of the office of Sanitary Commissioner in the North West Provinces and Oudh from Colonel Thomson, I M S.

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Lieutenant Colonel O. A. Patten, having resigned his appointment in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

VOLUNTEER CORPS

Royal Engineers (Volunteers) 1st Hampshire Surgeon Lieutenant J Kyffin to be Surgeon Captain. 2nd Lancashire (the St Helens) Surgeon Lieutenant-Colonel E F Hall resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle* 2nd Volunteer Battalion the Royal Fusiliers (City of London Regiment) Reginald Courtenay Gayer to be Surgeon Lieutenant. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment Surgeon Lieutenant J M Phillips resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 3rd (The Blythwood) Volunteer Battalion the Highland Light Infantry Surgeon Lieutenant J A Wilson to be Surgeon Captain.

VOLUNTEER INFANTRY BRIGADE

South Wales Surgeon Lieutenant-Colonel P E Hall, 1st Volunteer Battalion the South Wales Borderers, to be Brigade Surgeon Lieutenant Colonel, on appointment as Senior Medical Officer to the brigade.

THE ROYAL MILITARY TOURNAMENT

If any plea were necessary for the continuance of the annual display at the Agricultural Hall, Islington, the fact that the funds of the military charities are each year greatly augmented through its aid would amply suffice. But there are other and even better reasons which justify the holding of the Tournament. Not the least of these is the stimulus which it gives to recruiting, and so convinced are the authorities of this that should the present show prove successful—of which we presume there can be no doubt—it is proposed to repeat the same exhibition at Manchester almost directly. Another way in which the Tournament does an immense amount of good is by educating the public in things which pertain to military life and warfare.

On Wednesday, May 24th, the eve of the actual opening to the public, a full dress rehearsal and private view were given before the Press, the committee and members of the Tournament, and others. The first item on the programme, the naval display by seamen from H.M.S. *Excellent*, was highly appreciated by all who witnessed it and illustrated the ability and smartness of those who belong to our first line of defence. The musical ride by the G Battery of the Royal Horse Artillery was something more than a spectacular display and showed to great advantage the cleverness of the Royal Artillery drivers, while the cavalry display by the 6th Dragoon Guards (Carabiniers) and New South Wales Lancers was excellent. Both these exhibitions have a distinct educative value. It often happens that our army when engaged abroad is severely criticised by the public at home because of the ill results following upon what appears to have been some act of indiscretion. If those who judge so severely knew their subject it would often be obvious to them that what they term an act of indiscretion was not only excusable but absolutely inevitable by reason of the difficulties under which real war is conducted. And this is a point which a visit to the Tournament

will make clear to the arm chair critic. The cavalry display as presented at the Tournament brings this out very unmistakably and teaches a lesson that all should know who desire to sit in judgment upon our troops or their leaders.

The *pièce de résistance* of the show is, of course, the pageant which this year is entitled "Warriors of Britain" and is typical of the gradual evolution of the British army from the time of the Wars of the Roses to the present day. Under the direction of Mr. Clarkson, the well known costumer and perruquier, the details of the dresses have been made accurate in even the smallest details and the spectacle is quite equal to any of previous years. The gymnastic display by non commissioned officers under instruction at Aldershot, though not so showy as other items on the programme, shows well the excellence of the physical training which our soldiers undergo. The musical double-ride is pretty and effective and the combined display—the storming of Passer Sala—brings the performance to a close.

The sanitary arrangements of the hall are much the same as they were last year and indeed under the direction of the various officers who have been in medical charge of the Tournament little further can be done in a hall which is not peculiarly adapted for military displays. Major H E R. James, R A M C, is the Principal Medical Officer this year and he is assisted by Surgeon Major W R Crooke Lawless of the Coldstream Guards. Veterinary Major R Rowe, A V D, is the Principal Veterinary Officer.

ENTERIC FEVER IN QUETTA

As our readers are already aware enteric fever was very prevalent and fatal in the garrison of Quetta last year. It appears that, owing to changes in the head quarter staff at Bombay, some delay has arisen in giving effect to the sanitary recommendations submitted by a committee appointed to inquire into and to report upon the subject. According to the *Times of India* of May 6th Major General Sir William Galbraith has proceeded to Simla for the purpose of urging on the Commander in Chief the necessity of the measures proposed for minimising the risk of enteric fever in the Quetta garrison. Between August and December, 1898, the deaths from enteric fever in that garrison aggregated 75 rank and file, one officer, and about a dozen women and children, and unless the main recommendations of the scheme submitted are immediately taken in hand the enteric fever season will soon occur again, the prospect of which is something too alarming to calmly contemplate.

THE PUNJAB

Anti plague inoculations have become very popular in the Jullundur district where, over 4000 people in the infected area have submitted themselves to the process. The inhabitants of all the villages, such as Malpur, Garcha, and Buhara, have been inoculated.

We hear that Professor A E Wright of the Army Medical School, Netley, has at length succeeded in convincing the War Office authorities of the advisability of allowing inoculation against enteric fever to be introduced into the army. We hear that all soldiers are to be offered this benefit at no distant date. We believe that the outbreak of typhoid fever in South Africa and the immunity enjoyed by the men of the Royal Army Medical Corps who were inoculated before going to Egypt have been potent factors in bringing about this desirable ruling.

Mr Norman Hay Forbes, F R O S Edin, has been appointed a Member of the Royal Company of Archers, Her Majesty's Body Guard for Scotland.

PRESENTATIONS TO MEDICAL MEN—On May 14th, at the Queen's Walk School, Nottingham, on the occasion of the presentation of certificates to the successful members of the Midland Railway Ambulance Corps, Mr J F Blurton, M B Dnrh, was the recipient of a small dressing-case as a token of the esteem in which he is held by the members of the corps. On the conclusion last week at Leatherhead of the course of 12 lectures on first aid to the injured in connexion with the St John Ambulance Association, and a series of six lectures on nursing open to women, the honorary secretary, Mrs Davis, on behalf of those attending, presented Mr James Dunbar Brunton, M B Edin with a silver inkstand, appropriately inscribed, as a mark of appreciation of his gratuitous services.

the intestine The stone may either traverse the whole intestinal tract or may remain for a long time at one place. Colic or even volvulus may be the consequence and when the peristaltic action is not strong enough to urge the stone forwards ulceration and some degree of perforation may ensue It is essential that the diagnosis should be made as early as possible and the stone removed by operation. If stones caused by gall stones must be treated by the general state must be duly considered and in every case of colic the gall bladder ought to be examined

Obstruction of the Intestine by a Piece of Gaze
Professor KERN also described a case in which after a woman had been operated on for pyelitis a fecal fistula was formed and when it healed the patient felt quite well Four months after the operation she suffered from colic and a tumour could be felt on the right side of the abdomen Symptoms of ileus suddenly occurred and the abdomen having been opened 40 centimetres (16 inches) of the intestine were removed, the region of the first operation being quite normal A large piece of gaze was found in the removed portion of intestine. Owing to the impossibility of its having penetrated from the abdomen through the intestinal walls Professor Kern was of opinion that the patient, a hysterical woman, had swallowed the gaze—Dr KADDER (Brazilian) said that he had observed a similar case where colic was complained of 10 days after an operation for pyelitis and the wound spontaneously opened After some time a piece of gaze was passed by the anus and the patient ultimately succumbed to ileus and peritonitis The necropsy showed extensive intestinal lesions which rendered it probable that the gaze had made its way from the abdomen into the intestine Dr Kader then made experiments on animals and ascertained that a silk thread tied round the intestine after some time cut through the intestinal wall and it was found in the interior of the intestine

Coza Iara
Dr SUDER (Hamburg) read a paper on the Anatomical Conditions of Curvature in the neighbourhood of the Hip-joint, and drew attention to a spine on the top of the curve This spine, though not described in anatomical works, may also be found in normal femora; it originates from the osseous tissue between the trochanter and the head of the femur and in Dr Suder's opinion belongs to the epiphyseal fracture of the femur—Dr HORRIGSTER (Tubingen) said that the differential diagnosis between traumatic and non-traumatic coxa vara might be very difficult, especially when the history was obtainable Cases with contractions were always traumatic—Professor KOCHER (Bern) was of opinion that gentle coxa vara was caused only by over-weighting the femur As regards treatment, he preferred resection to osteotomy

Cartiloma of the Penis
Dr LUTHER (Tubingen) described a case of carcinoma of the penis where the lymphatic glands of the abdomen were attacked by metastases earlier than the inguinal glands He has studied the anatomy of the lymphatic vessels of the penis and has discovered that they are in connection partly with the inguinal and partly with the abdominal glands In cases of carcinoma the glands of both regions ought to be removed

Button for Intestinal Surgery
Dr SURAU (Göttingen) drew attention to some disadvantages of Murphy's button, especially its weight which might produce necrosis and perforation of the intestine. The construction of a button capable of being completely disintegrated was difficult and in Dr Surau's opinion it was sufficient to have a button which is partially disintegrable, leaving an insoluble portion small enough for easy expulsion. The button used by him consisted of two parts of decalcified ivory connected together by a metallic ring, and between

THE INTERNATIONAL MEDICAL CONGRESS, PARIS, AUGUST, 1900 (FROM OUR SPECIAL COMMISSIONER)

The French committee entrusted with the organization of the next International Medical Congress have already completed all the preparatory work which can possibly be done at this early stage. This, the greatest of all the congresses, will meet, as already announced, in 1900 from August 2nd to August 9th. It was in January, 1898, that the members of the organizing committee held their first sittings and they soon found that they had before them a most formidable task. The Congress should be divided. Acting on the experience acquired during the Universal Exhibition of 1889 a strong feeling was manifested that there had been too many congresses on the preceding occasion. This time the congresses have decided to unite their forces with a witness an amalgamation of congresses. Three or four general Medical Congresses. Thus, instead of having a separate International Congress on Forensic Medicine, another on Diseases of the Urinary Organs, and a third on Dermatology the members of these three congresses will join with the International Medical Congress and content themselves with forming sections of this one great congress. Probably the International Congress on Therapeutics will also follow the same course. On the other hand, much greater liberty or autonomy has been given to the sections. Indeed, it amounts to this, that each section will constitute, comparatively speaking, a small congress of its own, federated for common purposes with many other congresses meeting at the same time. In one respect this greatly simplifies matters the one circular serves for all the congresses or, rather, sections as they must now be called. On the other hand, the International Medical Congress already very unwieldy in consequence of the large number of its members, will have an even greater number of adherents than in former congresses. At the last congress, which was held at Moscow, there were about 7000 members inscribed and not far short of 5000 were actually present. But it is far easier to go to Paris than to Moscow, and therefore it is anticipated that a much greater number of members will attend the congress at Paris. How are all these many guests to be received? There must be at least one general meeting of the congress and where can

them a piece of caoutchouc was interspersed in order to make gentle pressure on the intestine. The buttons were covered with a metallic ring was easily expelled

Transplantation of Cartilage
Dr VOX MAXNEGOLD (Dresden) showed patients in whom he had, after resection of the larynx, performed transplantation of pieces of cartilage from the ribs. The patients had suffered either from strictures of the larynx caused by syphilis and tuberculous ulceration or from malignant growths. They could now be understood when they spoke; the results of the treatment must therefore be regarded as encouraging

Suture of Wounds of the Heart
Professor WEHR (Leipzig) described experiments on Suture of the Heart Muscle in Animals after partial resection of several ribs and opening the pericardium the heart was incised and the wound sutured. The hamorrhage was stopped by digital compression—Professor KERN (Frankfort) said that at the meeting of the Congress in 1897 he reported a case of Wound of the Heart in which he had operated. The patient still remains quite well

Papers were also read by Professor HORVA and Professor LORENZ on Congenital Dislocation of the Hip-joint, by Professor TILMANZ on Fractures of the Skull, by Dr BERDA, Dr KUTVETZ, and Dr VOX MAXNEGOLD on Tuberculous Osteitis, by Dr HERCZEL and Dr VOX BECK on Gastro-enterostomy, by Professor KRAUSZ on Resection of the Occipital Nerves, and by Dr JORDANZ on Pericarditis Professor VOX BERGMANN was elected president of the next Congress

"GONORRHOEAL SALPINGITIS"

To the Editors of THE LANCET

SIRS,—In THE LANCET of May 20th I am reported (p 1367) as having said during the discussion on Gonorrhoeal Salpingitis at the British Gynecological Society on May 11th that in cases of salpingitis the tubes were "sterile in 60 per cent of cases, the gonococcus was found in 20 per cent, and other micro-organisms in the remaining 20 per cent. In the last group the infection had no doubt been primarily gonorrhoeal and there was a secondary infection by the bacillus coli or the tubercle bacillus." I cannot accept responsibility for this statement as to the tubercle bacillus. What I did say was that probably some of the cases included in the last group were primarily due to a gonorrhoeal infection but that there had occurred a secondary infection by some other micro-organism, notably by bacillus coli communis. I did not say anything as to tubes primarily infected by the gonococcus being specially liable to subsequently become infected by the tubercle bacillus.

I am, Sirs, yours faithfully,
MAY 20th, 1899. ALEXANDER G R FOULERTON

"A CRITICISM OF THE MORE COMMONLY EMPLOYED TESTS FOR ALBUMIN IN URINE"

To the Editors of THE LANCET

SIRS,—In leaving this subject pending further investigations I would like to point out definitely how the matter stands. In my paper I looked at the matter from the clinical point of view and did not push the tests to a chemical conclusion. I have repeated my experiments twice since and it may be taken as certain that, judging from egg albumen in aqueous solution and pushing the tests to a chemical conclusion, (1) taking the excretion of urine at 50 ounces per diem the heat test will not detect a loss of albumin (dried at 100° C) of less than from three to three and a half grains per diem, (2) under the same conditions the nitric acid test will detect a loss of a quarter of a grain per diem, and (3) a solution of carbolic acid in absolute alcohol is almost as delicate as the nitric acid test.

The heat test was applied in the usual way—namely, by heating the upper part of the tube to ebullition and after observation heating again after the addition of a drop of acetic acid. Picric acid is much more delicate as a chemical test than I made it in my paper, but the fineness of the cloud, its colour, and the fact that at an early stage of dilution it is clear to transmitted light make its clinical value stop probably at a loss of about two grains of albumin per diem. The investigations will be continued with serum albumin and in mixtures. Dr Brodie, my fellow assistant to the Professor of Physiology in Glasgow University, has undertaken an independent investigation. We use different balances, pipettes, and weights and compare results of series of experiments, so that it is not likely that any error in observation will escape detection.

I am, Sirs, yours faithfully,
GLASGOW, MAY 22nd, 1899. WALTER COLQUHOUN

THE TREATMENT OF TETANUS

To the Editors of THE LANCET

SIRS,—I have read with considerable interest the cases of tetanus recently recorded in THE LANCET. It occurs to me that a great opportunity has been lost of harmonising practice with theory. No cultivation appears to have been made in any of the cases recorded. If the drum stick bacillus of Nicolaier be the actual cause of the disease in question and, being an anaerobic organism, of necessity confined to the tissues in the immediate vicinity of the wound and from thence distributing toxin to the general system, surely the indication would be freely to excise the part, and if necessary to amputate, in either case taking special care not to inoculate the new wound. I must frankly confess to a feeling of disappointment at this, not having been done, as two of the cases ended fatally.

I am, Sirs, yours faithfully,
STEPHEN TOWNSEND, F.R.C.S. Eng
Inner Temple, May 23rd, 1899

PAROTITIS AND INFLUENZA

To the Editors of THE LANCET

SIRS,—In an annotation in THE LANCET of May 20th entitled "The Bacillus of Influenza," mention is made of the occurrence of parotid symptoms in conjunction with the presence of the, Canon Pfeiffer, bacillus in the bronchial mucus. This is the first time I have seen in print a suggestion that parotitis may be a complication of influenza and it will accord with the view I took of a case which came under my notice early in the year. In the early part of February I was in attendance for well marked influenza on two children in a young ladies' school. The head mistress of the school, who, by the way, is a rheumatic subject, nursed them, and in a short while fell sick herself in the same way. On Feb 11th she was convalescent and two days later, after being downstairs, she had a rise of temperature and pain in the parotid regions—in short, went through a mild attack of what appeared to be mumps. Arising in a school I was eager to trace the source of infection, although I was doubtful whether the complaint was true mumps. All I could ascertain was that a small child had had influenza and had thereafter a similar attack to that from which my patient was suffering, that it was considered an influenzal manifestation, and that she was allowed to mix with others—indeed, she attended at the school some three weeks or more prior to my patient contracting the parotid symptoms. I may say that no other cases of mumps arose in the school, although if the little girl was the source of infection she would be far more likely to infect some other child than to infect the headmistress, of whom she saw very little. I should add that my patient although in middle life had never had mumps, though of course I isolated her so far as was possible. I thought at the time that the complaint must be an influenzal parotitis and not true mumps, but I have not seen any other such cases and have not heard of any other than the little girl mentioned above. I could not get precise dates as to when this child came into the school. It would be interesting to know if many of your readers have met with such a complication or sequela of influenza. I should not have thought of mentioning the matter in print myself but for your annotation. I crave your indulgence to allow me to remain anonymous on this occasion and will subscribe myself,

Yours faithfully,
LONDON, MAY 23rd, 1899. M D CANTAB.

THE GERMAN SURGICAL CONGRESS

(FROM OUR BERLIN CORRESPONDENT)

(Concluded from p 1190)

Phosphorus Necrosis

DR VON STUBENRAUCH (Munich) said that in experiments made for the purpose of elucidating the action of phosphorus on the bones he trephined the mandibles in dogs and guinea pigs and injected phosphorus through the alveolus, but necrosis did not ensue. He then exposed the animals to vapours saturated with phosphorus and obtained the same negative result. In order to imitate as much as possible the conditions which the workpeople encounter in match factories the animals were sent to a match factory to be left for a certain time in the drying room which is the most unhealthy department. Although the periosteum had been previously removed from the mandibles no necrosis took place. Dr von Stubenrauch therefore concluded that the typical necrosis of workers in match factories is not caused by the vapours alone but that a specific predisposition must also exist.

Ileus caused by Gall stones

Professor REHN (Frankfort) reported the case of a man operated on for strangulated umbilical hernia. The intestine being gangrenous it was resected and a large gall stone was found in it. The patient recovered. Professor Rehn said that gall stones may produce the symptoms of ileus either by mechanical occlusion or by causing inflammation of the intestines. A reflex occlusion, as suggested by Professor Koerte, may sometimes occur, sometimes the stone by conveying virulent germs may irritate the mucous membrane of

in manner in which plague officials are treated as far as the English medical men and nurses are concerned there seems to be an official passive opposition against them. There is an entire want of liberality of treatment and unnecessary difficulties are continually being placed in their way.

The claims of Lush's new curative serum apparently want pushing it one may judge from a report recently prepared by Dr. Galliot and forwarded to the Municipal Commission of Bombay. If the cases are allowed to speak for themselves they pronounce it a failure. As a matter of fact, the published figures are wholly misleading because the cases were practically selected ones. At the Arthur Road Fever Hospital and at the Mubetta Hospital from Jan. 29th to the end of February 68 patients were treated, of whom 48 died and 20 recovered, giving a mortality rate for even these selected cases of 70.6 per cent. The whole hospital mortality for the month of February was 79.41 per cent. The microscopic basis of such returns makes the whole experiments and the report absolutely valueless, and when it is remembered how many cases are brought to the hospitals to die within a few hours which, of course, are not subjected to the curative serum treatment but go to swell the mortality returns of the hospitals it will even be thought that the curative serum treatment must have raised the mortality rather than reduced it. In another report submitted by Dr. Choksi of the Municipal Fever Hospital a further series of cases is referred to which were treated during the month of March. 74 patients were treated, of whom 49 died and 25 recovered, giving a mortality rate of 66.21 per cent, against 79.48 per cent in cases not treated with the serum. It must here again be noted that all cases which were moribund and all those which had gone over or over days and were either semiconscious or comatose were excluded. The cases which prove fatal within 24 hours after admission to hospital amount to over 30 per cent, and a certain proportion of cases we after seven days of illness and during convalescence. To say that the cases selected represent a fairly average type of acute cases is absurd. Then again it is asserted that the serum treatment has been put to as severe a test as possible during the height of the epidemic. To pick cases is neither a severe test nor a scientific method and epidemic has been known for its extreme violence is discounted by the fact that the mortality of plague cases in the same hospital at the same time last year was within a fraction of what is recorded this year. I regret to be obliged to state that there is no satisfactory evidence to show that Lush's serum can reduce the mortality rate in the slightest degree.

May 1st.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Malina and Mongitore. Address by Major Han, I.M.S., at University College

Major Ross, I.M.S., the recently appointed lecturer in the School of Tropical Diseases, delivered an interesting illustrated lecture on the Relations of the Malarial Parasite to the Mosquito in the Physiological theatre of University College. The lecturer said that malaria was not so dramatic a disease as cholera, it did not kill so quickly, but it killed far more people. In India it killed about 5,000,000 people a year. It was also a politically important disease because it checked the progress of civilisation in districts the richest in the world killing more of our army than were killed by the enemy. Malina had been found to be due to a parasite in the blood. Of this he was absolutely certain, having studied the subject for 10 years in the tropics. The lecturer explained how a parasite gradually developed, destroying a corpuscle of the blood and leaving it a mere shell, when fully developed it scattered and attacked other corpuscles, destroyed and poisoned them likewise. Even if not so numerous as to cause fever they bred in comparatively small numbers, they caused an undifferentiated condition of health. The treatment was quite the reverse of that which was proposed. What they required to know was how malarial fever was produced. To do so they must find the parasite in external nature and the problem had been solved by Dr. Patrick Manson. Besides these forms of malarial parasites which

Dr. Hope in his annual report for 1898 commenting on the deaths in Liverpool due to excessive drinking says that there appears to be no reason to doubt that the total amount of drunkenness in the city is diminishing and there is evidently a gain to proportion in the decrease in the amount of drunkenness in the open streets. There is, however, room for doubt whether there is any diminution in the gross abuse of alcohol within doors in the more equal parts of the city. 10 years ago—namely, in 1889—poison cases of drunkenness numbered 16,000, by rapid annual decreases the number last year had diminished to 4,000. But if the deaths from excessive drinking in the two years be compared there is found to have been only a slight diminution in the deaths amongst males from that cause, while the deaths of females from a similar cause have actually increased. Deaths from excessive drinking are localised and it is in the districts where they are most numerous that the general death rate is highest and the proportion of deaths in work-houses is greatest. Inquests were held during the year on the bodies of 204 persons—viz., 43 males and 42 females whose deaths were due to excessive drinking, 55 males and 33 females whose deaths were accelerated by excessive drinking, and 13 males and 17 females who were actually injured by accident or suicide whilst under the influence of drink. There were two deaths from violence caused by persons under the influence of drink, the persons who were killed being also intoxicated at the time. Dr. Hope deplores the vice of intemperance as a cause of poverty, disease and death and its paralysing influence on the efforts of the sanitary authorities in the direction of improving the condition of the masses.

Drunkenness in Liverpool

The foundation stone of a new wing to the infectious diseases hospital at Widnes was laid by the chairman of the Widnes Health Committee on May 16th. For some time past the hospital had proved inadequate for the requirements of the borough and it was felt by the medical officers of the hospital that it was essential to erect a new wing of the hospital to cope with such a contingency. The new wing of the hospital will contain the house surgeon's apartments, and nurses' room, a surgery, and store-rooms. The entire fever ward will provide 10 beds for male and 10 beds for female patients. The joint Health and Works Committee of the Widnes Council have decided to extend their infectious hospital at Mill Lane at a cost of £90,000.

Report of Bacteriologist to the Liverpool Workhouse

The select vestry, upon the recommendation of the medical officers of the Liverpool Workhouse, have decided to appoint a bacteriologist to the workhouse hospital. Hitherto the medical officers had endeavoured to utilize this science through the favour of the professor of pathology at University College who had gratuitously examined many specimens for them. The Mill road Infirmary of the West Derby Union possesses a well equipped laboratory and it was felt by Dr. Alexander and Dr. Robertson that the workhouse hospital was being left behind other Liverpool hospitals. They did not ask for laboratories or expensive apparatus in view of the close proximity of the Thompson-Vales laboratories. It was unanimously agreed to appoint Professor Boyce as bacteriologist to the workhouse hospital at an annual salary.

Dr. Manson came to the conclusion that the malarial parasite when it left the human being was carried on in the mosquito, and therefore that malarial fever was propagated by the mosquito. The lecturer described how in the tropics he followed out Dr. Manson's theory beyond the point where he felt it would be impossible to cope with such a contingency. It was hoped that this species of malarial mosquito might be exterminated in certain districts and this he mentioned would be the subject of a future lecture.

Hospital Extension at Widnes and Wallasey

The foundation stone of a new wing to the infectious diseases hospital at Widnes was laid by the chairman of the Widnes Health Committee on May 16th. For some time past the hospital had proved inadequate for the requirements of the borough and it was felt by the medical officers of the hospital that it was essential to erect a new wing of the hospital to cope with such a contingency. The new wing of the hospital will contain the house surgeon's apartments, and nurses' room, a surgery, and store-rooms. The entire fever ward will provide 10 beds for male and 10 beds for female patients. The joint Health and Works Committee of the Widnes Council have decided to extend their infectious hospital at Mill Lane at a cost of £90,000.

such a meeting be held? There is but one hall in Paris which will hold about 10,000 persons and that is the great hall of the Trocadero. But in discussing this matter with me the general secretary of the congress, Dr Chaffard, displayed a strong prejudice against this hall—he urged that the acoustics were bad and, above all, that the hall was ugly. It was only necessary to look round the apartment which Dr Chaffard inhabits to realise that he has a very keen and artistic appreciation of the beautiful. He was eloquent in expressing the desire that the congress should meet in some place where the decorations would be artistic and suitable to the occasion. Undoubtedly the new hall of the Sorbonne is admirably adapted for the purpose, only it is not half big enough, but he could not bring himself to forgive the Trocadero its inartistic appearance. I suggested a theatre, but even the Grand Opera can comfortably seat only 3000 persons. What will be done to meet this difficulty has not yet been decided.

There are to be 23 sections in all, and so far as the sectional meetings are concerned they can be easily housed and this in an appropriate manner. Thus the Section of Dermatology will meet at the St. Louis Hospital for Venereal Diseases, where a magnificent museum will be at the disposal of the members. The Section on Urinary Diseases will meet at the Necker Hospital, where that class of complaint is treated. The Collège de France, the Sorbonne, and the faculty of Medicine will be at the disposal of the other sections. To obtain reporters for all these sections has been a colossal undertaking. Contrary to the policy followed by the organisers of the International Congress of Hygiene, the organising committee of the International Medical Congress have addressed themselves more particularly to foreigners. Thus, for instance, when it is judged necessary to appoint three reporters on any given subject there will be only one French reporter, the two others will belong to some other nationality. The French organisers felt that as a matter of courtesy, they should give to their guests the largest share in the proceedings. But for this purpose it has been necessary to undertake an amount of correspondence which can scarcely be appreciated except by those who have had some experience in this sort of work. As a result of this vast correspondence some 250 medical men, of whom only a third are Frenchmen, have undertaken to act as reporters on the various subjects which are to be submitted to the 23 sections. Some sections will have reports on six different questions, some on only three, but four questions per section is the more general rule. All these reports will be written in French, English, or German, but those who report in either of the two last mentioned languages are requested to add a short summary of their reports in French, if they cannot do this themselves. Then the organising committee will endeavour to have these summaries translated into French for them. The reports will be published in full and will constitute as it were the official subjects of discussion.

Apart, however, from these reports, individual members of the congress are at liberty to send any communications they choose which are suited to the section of the congress which they propose to attend. These communications or papers can be read in the sections, but the committee do not undertake to publish more than a summary of them, unless they prove to be of exceptional importance. A circular giving full details of all the reports expected, the names of the reporters, of the presidents, of the secretaries and of the committee men of the 23 sections, the rules of the congress, the form which has to be filled up by intending members, and other information is now in the hands of the Government printers. This circular will be issued in French, English, and German, and will be despatched to all countries during the course of this summer. For the present the organising committee have nothing more to do. They must now wait for the replies which this circular will elicit. In the meanwhile the organising committee are anxious to express their high appreciation of the friendly support which they have received from members of the profession in all countries. The letters which they have sent abroad have met with a prompt response and this has greatly facilitated the work of organisation.

The organising committee are now desirous to impress on intending foreign visitors the absolute necessity of forming national committees or in some other way of taking measures to ensure that there shall be the necessary accommodation for them when they reach Paris. The United States of America is as yet the only nation which has provided for

this. The American Government has a representative in Paris who is organising for the reception of all American exhibitors and of all Americans who mean to attend any of the congresses. This agent will secure rooms for them in advance. The British members of the congress would save a great deal of trouble and expense if they constituted a British committee, created a common fund, and despatched a commissioner to Paris. This representative by contracting for several hundred rooms in the different hotels could obtain them at a cheaper rate. Wholesale transactions are always less expensive. A member of the congress arriving in Paris alone would be charged some exorbitant price for his room and might even fail altogether to obtain a room. The overcrowding in consequence of the Universal Exhibition and of the International Medical Congress threatens to be unprecedented. The organising committee cannot undertake to find lodgings for the thousands of visitors expected, they will have work enough to do in attending to the business of the congress itself. The general secretary was therefore very anxious that I should endeavour to impress upon the British members that it was absolutely necessary that they should institute some sort of organisation of their own with representatives in Paris to secure the necessary accommodation. This must be done a long time beforehand. Every member of the congress must make up his mind when he is coming to Paris, how long he desires to remain there and what sort and number of rooms he will require, and these he must secure before leaving England, otherwise he will run a great risk of being stranded in the streets of Paris and will become the helpless victim of every form of extortion. All this should be seen to and in good time. Meanwhile all correspondence relating to the International Medical Congress should be addressed to the general secretary, Dr Chaffard, 21, Rue St. Guillaume, Paris.

Paris, May 15th.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Plague in India — Complaint from the English Medical Men and Nurses — Further Experiments with Curative Serum

PLAGUE returns for India for the week ending April 30th show a further great reduction, the deaths having fallen to 1184 in the Bombay Presidency, of which Bombay city reports 360 and Karachi city 207. The Madras Presidency is almost free. In the Mysore State, Mysore city, and the Kolar goldfields the cases are also fewer. In the Bengal Presidency there were 141 deaths reported, of which Calcutta furnished 125. The Punjab returned 25. The Central Provinces, the Hyderabad State, Rajputana, and Assam are practically free. The rapid fall in Bombay city exactly corresponds with the experience of previous outbreaks and amounts to a diminution of nearly 200 deaths for every week since the climax towards the end of March. In Calcutta the outbreak still keeps subdued and shows no sign of increased virulence. The cases are now fairly well scattered over all parts of the city. In Karachi the disease has shown a decided change for the better and the third outbreak is now probably on the decline.

Many complaints are being made by the medical men and nurses who have come out from England for plague duty and little inducement appears to be offered to them to remain. I understand that in consequence of so many having resigned fresh help again is being sought for. It would surely have been better to keep if possible those who have partially learnt the language and know something of the habits and customs of the natives. Petty annoyances in the way of official difficulties in getting pay, inadequate lodging accommodation for the sisters, unreasonable opposition to a few days' casual leave after continuous service over a considerable period, prolonged delay in replying to official communications in volving anxiety and expense to the applicants, bad management with regard to duties, and insufficient subordinate native assistance are some of the additional grounds which have recently given rise to so much dissatisfaction. I understand that volunteers for plague duty were recently called for from all parts of India and that only three medical officers were willing to come forward. This, considering that the service men get extra pay, shows the unsatisfactory

I.R.C.P. Lond, Torquay, James Wilson M.B. Brearley, I.R.C.S. O.M. Edin, Edinburgh; Henry John Forbes Simpson, M.B., Edin, New Zealand, Wyndham Aschmole, M.B., I.R.C.P. S. Edin, Amivich, Anglessey

Edinburgh Royal Infirmary

At the weekly meeting of the Managers of the Edinburgh Royal Infirmary, held on May 22nd, it was agreed to open Blair House the nurses' rest at Colinton, on June 1st, but it was stated that the opening would be quite informal.

Monro's Asylum

The new house for private patients in connection with Monro's Asylum was opened on May 22nd. Carnegie House, as it is designated, was commenced four years ago and consists of three blocks. The central block is occupied by a large hall on the ground floor and a dining hall and the administrative department on the first floor. The east block is intended to accommodate male patients and the west block is for female patients. The estimated cost was £16,500 but about £30,000 have been expended on the building. It will accommodate 60 patients. The building is heated by the Stirling steam with two in winter time, and the drainage and sanitary arrangements are excellent. The architect was Mr. W. Kelly of Aberdeen.

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Irish Medical Association

The Council of the Irish Medical Association met in the Royal College of Surgeons in Ireland on May 17th to consider the report to be submitted to the annual meeting arranged to be held on June 20th not in Dublin as heretofore but in the Examination Hall, Queen's College, Cork. The President and Council of the Queen's College, Cork, gave an entertainment to their visitors and an annual dinner will be held at the Royal Victoria Hotel. The members of the medical profession in Cork will also entertain the members of the Association by an excursion to view the harbour and to witness the regatta at Queenstown.

Memorial to the late Dr. Haughton

The Rev. Dr. Haughton though a highly qualified member of the medical profession never engaged in medical practice, yet was widely known among physicians as well as among the general scientific public. On the occasion of the opening of the memorial building recently erected in the Zoological Gardens, Dublin, which took place on May 19th, addresses were delivered by His Excellency the Lord Lieutenant Field Marshal Lord Roberts, V.C., K.P., Sir Robert Ball, and others. The ceremonial was attended by a very large and representative audience.

Linnæus Board of Guardians

A curious point came before the Linnæus Board of Guardians at their weekly meeting on May 22nd, when Dr. Watson, the medical officer of the workhouse, reported that by the instructions of the Local Government Board for Ireland a number of old, weak, and debilitated people had been getting extras such as eggs, milk, or tea although not under any treatment or in the hospital. He believed that he had no power to order anything for them unless they were in the hospital. He wished the guardians to ask the Local Government Board if these extras were to be discontinued or if they were to be continued, who was to order them. He had ordered none for the next week until he received instructions. The board of guardians ordered the extras, but Dr. Watson's point is an important one. Can hospitals? The Local Government Board and their medical officers are charged with the duty of giving medical relief to the poor and whether the application, having regard to the doctor's charges, could not be made to pay for medicine and advice. It appeared to the Local Government

Lodine's Ear Water

At the sitting of the Academy of Sciences held on May 1st, M. Armand Gahster said that the general opinion was that iodine existed in sea water in the form of alkaline iodides or earthy salts. On the contrary, he had found that sea water taken some distance out and either from the surface or at no very great depth contained no inorganic iodides. The whole amount of iodine, with the exception of a very insignificant trace, existed as bodies of organic composition. A portion of this organic compound is fixed in organic bodies such as zoölogues, algae, sponges which live on the surface or a little below it and make up the "plankton" of the high seas. Four fifths of the iodine of the sea is composed of soluble organic bodies they are accumulated along the shore under the forms of masses of foam containing zoölogues and diatoms. They are charged with iodine and being also partly macerated.

Queen's College (Cork) Athletic Sports

The Queen's College (Cork) Athletic Club held their annual meeting on May 13th. The contests were good and though the weather was very unfavourable there was a large gathering in the South of Ireland, a cycle polo match, the first played in the South of Ireland, excited considerable attention. The club dinner was held in the evening, among the guests being Professor Hartog, Professor Charles, Professor Cory and Professor Bergin. In the absence of the president of the club Professor Cory presided. One of the students proposed the toast of "The Professors of the College." Professor Charles replied in a felicitous speech and referred to the mutual advantages of the professors and students meeting socially. Several songs were contributed by the students and a very enjoyable evening was spent.

Successes of Queen's College (Cork) Students at the Royal University Examination

At the recent examinations for the degrees of M.B., B.Ch., B.A.O., held by the Royal University, out of about 40 candidates who presented themselves only 17 were successful. The total "mortality" was therefore well over 50 per cent. Nine of the candidates were educated in Cork and seven out of the nine were successful. Three of the seven obtained "upper pass."

Belfast Royal Hospital

At a meeting of the staff of the Belfast Royal Hospital held on May 22nd Dr. J. A. Lindsay was elected secretary in place of Professor Whitham resigned. Mr. West was awarded the Coulter exhibition. Professor Byers, in the name, and at the request, of the staff expressed to the chairman, Professor Cunningham, the very great pleasure with which they all welcomed him back again after his enforced absence and hoped that he might long be spared to act as their permanent chairman. They regarded him not merely as head of the profession, but personally they were nearly all his old pupils and his constant attitude towards them had been that of "guide philosopher and friend." In reply Professor Cunningham thanked his colleagues very warmly for the kind expression of their feelings towards him.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Manchester Parks and Playgrounds

IF Manchester is named, the mental eye of the untraveller Southerner sees a dirty, smoke enveloped wilderness of cotton mills and mean streets inhabited by a semi barbarous race of sickly and stunted factory hands. It is not quite so bad as that, but even to day the conditions are not favourable for the physical development of the city operative and Manchester has but slowly learned the importance of providing open spaces for recreation and health. The total area within the city boundaries is at present 370 acres, divided into 23 open spaces, the largest, Boggart Clough, containing 76 acres, the rest varying in size down to one acre in extent. The euphonious name Boggart Clough, or Boggart's Hole Clough, was given presumably from its having the reputation of being haunted, "boggart" being the vernacular for ghost or spectre. In addition to these there are various small open spaces valuable as playgrounds for the children and portions of the larger ones also are set apart for the same purpose. The suburb of Crumpsall is one of the last to be provided with a park, which is to be opened shortly by the Lord Mayor. It occupies 12 acres and when completed will have cost about £21,000. A more recent and comparatively less costly acquisition is at Newton Heath, where the Brookdale estate of 45 acres, together with a mansion, has been bought by the corporation for £26,500. Nothing need be said as to the importance and value of these open spaces to the working classes, but the idea that it was the duty and interest of the corporation as guardians of the public health to provide them instead of leaving it to private benevolence is, unhappily, of recent date. Had it been otherwise large open spaces and parks might have been secured at far less cost than is now required and the amoeba like growth of whole districts of brick would not have been allowed without a much more generous distribution of air spaces than we find at present. It is a matter of keen regret to many that owing to the dilatory and haggling tactics of the corporation Trafford Park with its 1100 or 1200 acres was lost to Manchester and snapped up by a syndicate.

The Salford Sanatorium

The Salford Corporation find it necessary to extend the Ladywell Sanatorium and wish to borrow £19,550 for the purpose. During the inquiry by the Local Government Board on May 12th Mr. Mullen, the medical superintendent, said that there was a general want of accommodation and had been, especially as to cases of scarlet fever and enteric fever, during the last three years. At present they could take 96 scarlet fever and 48 enteric fever cases, and the proposed addition was for 48 beds for the former and 32 for the enteric cases, with 12 beds for the nursing staff. Salford was increasing immensely and, as the chairman of the Health Committee said, "the Ship Canal has done a good deal towards that." He also said that 73 per cent of the notified cases came into the hospital and that there was no difficulty in getting cases to come in. Mr. Tattersall, the medical officer of health, confirmed Mr. Mullen's statement as to the desirability of extension. He was asked by the inspector if there was any smell from the Ship Canal and said "There is still a little in summer, but it is getting less year by year," owing to the efforts of the Mersey and Irwell Joint Committee. We must be thankful for this if it is really so and not due to the deadening of the olfactory sensibility of Salford.

Accommodation for Lunatics in the Chorlton Union

At the meeting of the Chorlton Guardians on May 12th the chairman drew attention to the want of accommodation for lunatics which he described as disgraceful. Instead of sending them to the workhouse at Withington "they ought to be in an asylum." For the past two years there had been the greatest difficulty in getting lunatics, especially males, into the county asylums. With females the difficulty had been less, but it was said that "the Lancaster Asylum was now full up." Dr. Rhodes said that the Asylums Board were doing their best to meet the demand for accommodation. He hoped that in about twelve months a part of the Winwick Asylum would be opened. They were also putting up buildings at the asylums near Preston and at Prestwich and Lancaster. It would seem on the face of it as if the

authorities could not provide rapidly enough for the increase of lunacy.

Appointing Two House Surgeons for the Union Workhouse.

At the same meeting the Chorlton Guardians appointed a senior and a junior house surgeon for the workhouse. One of the lady guardians said that there were nine applicants, six of whom were women, but two of the men were chosen and recommended for the appointment. She wished to know if the women were left out because they were women. "They stood as a proper board and if the women had been dropped out on account of their sex she did not think that they could claim to hold that position any longer." She was informed that the sub-committee had brought before the board the two candidates whom they thought most eligible. Dr. R. Kelsall and Mr. W. H. Richardson were appointed. By and by sex will probably tell against a man's appointment.

The Requirements of the University of Edinburgh

THE Court of the University of Edinburgh had recently before them a report from the committee appointed to draw up a statement and appeal for funds for University purposes, in which it was stated that the funds required for the equipment of the Public Health Laboratory and for the preparation of a library catalogue had been provided, the former by the generosity of Mr. John Usher of Norton and the latter from the munificent bequests of the late Sir William Fraser. For the library, however, funds are still urgently required. The most pressing wants are (1) a fire-proof room for the storage of rare books of the fifteenth and early sixteenth centuries and the MSS., which number about 7000, (2) a fund, amounting at the lowest figure to £25,000, for the purchase of scientific and literary journals and of larger works of reference, and (3) extensive structural changes and new book-cases, costing at least £5000, or, what would be much more desirable, a new and suitable building for the library. Another direction in which it would soon be necessary to spend money was the establishment of the Physical Laboratory. The construction and equipment of this laboratory would be a large undertaking, but it was one which would have soon to be faced if the scientific reputation of the University were to be maintained.

Chair of Physiology in Edinburgh University

The complete list of candidates for the vacant chair of physiology in the University of Edinburgh is as follows: Dr. Wace Carlier, Lecturer on Experimental Physiology and Histology and senior assistant to the late professor of physiology, University of Edinburgh; Dr. Noel Paton, superintendent of the Research Laboratory of the Royal College of Physicians of Edinburgh; Lecturer on Physiology in the School of Medicine of the Royal Colleges, Edinburgh, Co., Professor Reid, Professor of Physiology in University College, Dundee, St. Andrews University, Professor Schäfer, Jodrell Professor of Physiology in University College, London, Professor G. N. Stewart, Professor of Physiology and Histology in the Medical School of the Western Reserve University, Cleveland, Ohio, Professor Stirling, Brackenbury Professor of Physiology and Histology, Owens College, Manchester, and Professor Anderson Stuart, Professor of Physiology in the University of Sydney.

Tuberculosis Congress in Berlin

Professor Sir Thomas Grainger Stewart goes to Berlin to attend the Congress on the Prevention of Tuberculosis as an honorary member and as the delegate of the Senatus Academicus of the University of Edinburgh. Bailie Pollard goes to represent the city of Edinburgh.

Royal College of Surgeons of Edinburgh

The following gentlemen, after having passed the requisite examination, were on May 16th elected ordinary Fellows of the Royal College of Surgeons of Edinburgh: John Basil Hall, M.B., B.O. Cantab., M.R.O.S. Eng., L.R.O.P. Lond., Bradford; Charles William Donald, M.B., O.M. Edin., Edinburgh; Edward William Scott Carmichael, M.B., O.M. Edin., Edinburgh; Robert Black Parves, M.B., O.M. Edin., Edinburgh; John Harley Gough, M.R.O.S. Eng.,

Research officers in Cuba which vindicate the belief so frequently and emphatically expressed by Americans in former years that Cuba would be a veritable garden spot of the tropics and a goodly if Spanish rule were ended. The vile conditions of the cities of the island, breeding diseases of the malignant type, are now, however, being rapidly supplanted by cleanliness and the improvement from a sanitary view is remarkable as well as pleasing. The deaths from all causes continue to decrease yearly, while the present mortality is the lowest recorded for many years.

The Suicide of Dr Laforest

Further details are to hand concerning the recent suicide of Dr Laforest who was accused of certain offences at a home for destitute children. Hearing that he was to be prosecuted he went to Paris on a Sunday to give himself up, but finding the Palais de Justice shut he returned home and dreading the scandal which would attach to his name even if he were acquitted he determined to commit suicide. After talking the matter over with his wife he bade farewell to her and his two children. He then went into his consulting room, stopped up all the windows and the door, turned on the gas, and lay down on the sofa. While awaiting death he continued to converse with his wife who in her turn, from the other side of the door, besought him not to lose courage. When she could no longer hear him speaking and concluded by a dull thud that she heard that he had rolled off the sofa on to the floor she went to fetch the police. When they arrived two hours later and forced the door they found nothing but a corpse. The wife has been arrested as an accessory to his murder.

Gunshot Wounds of the Chest

At the meeting of the Academy of Medicine held on May 16th M. Lucas Championnière showed a patient who had been under his care and who had completely recovered from a revolver shot fired point-blank full in the chest. The patient was brought to the hospital in a very restless state with an irregular pulse and frequent threatnings of syncope. On the day after a large zone of dulness appeared in the chest. The treatment consisted in immobilisation and rest, a restricted diet, and purgatives as soon as the patient could bear them. A radiograph disclosed the fact that the ball, having traversed the chest from above downwards, had lodged in front of the twelfth rib, there it still remained. M. Lucas Championnière compared with this case another which had been under his care some eight years ago. It was that of a young man who had been wounded at the apex of the right lung by a broken foil and who rapidly recovered by being kept perfectly at rest. The skilful surgeon of the Hôtel Dieu is of opinion that in the immense majority of penetrating wounds of the chest non interference should be the rule, being the exact contrary to what obtains with regard to wounds of the abdomen, looking at the probable outcome of the two conditions. The patient should be kept absolutely at rest and even a slight movement, as, for instance, to practise auscultation, may be fatal. The fundamental principles of treatment in penetrating wounds of the chest are as follows. If possible avoid moving the patient and immobilise him on the scene of the accident. All conversation must be avoided, all drink must only be given in small quantities and then cold if hæmoptysis should continue, the bowels must be kept well open if the patient can bear it, and the diet should be confined to liquids for a long time. Injections of artificial serum in small but repeated doses are useful, and the pain and restlessness can be controlled by injections of morphia.

Paying Patients in the Hospitals

The governing body of the Assistance Publique has again been discussing this delicate question. It had already decided that there were two classes of patients in easy circumstances who might be admitted into the hospitals—namely, strangers and foreigners passing through Paris who could not be treated in a hotel and patients afflicted with infectious diseases. The council has now added a third class—that is to say, those inhabiting a commune who have to undergo a severe operation but cannot be operated on in their own homes or in a *maison de santé*. Such patients will have to pay a much higher fee than merely the net cost of their maintenance. Unfortunately, the council laid down no regulations as to honoraria to the surgeons who will thus have to operate gratuitously on rich patients filling their beds who are known to be able to pay. The council considered a demand made by the mutual aid societies that their members should have a certain number of hospital beds reserved for them, and this, too, gratuitously, without the society having to pay anything for maintenance. The council, however, refused to grant this demand on the ground that it would be an undue favouring of members of friendly societies and would press very hardly on the really poor.

New Professors

The chair of Historical Medicine at the Faculty of

Medicine at Paris which has been vacant for six months has just been filled by an election which took place on May 18th. There were three candidates, all neurologists and former pupils of Charcot—M. Brissaut, M. Pierre Marie, and M. Gilbert Ballet. M. Brissaut was unanimously elected. The new professor is well known as one of the most gifted and brilliant writers of the medical faculty. Although he has not directly interested himself in the history of medicine he has written a little book upon popular terms for illnesses and matters having to do with medicine and their origin which is a veritable *chef d'œuvre*. The Municipal Council has not yet given its decision as to who is to occupy the new chairs of Gynæcology and Pædiatrics which have just been founded. To the names of those actually in the field—namely, Dr Richelot, Dr Pozzi, and Dr Hartmann—must be added that of Dr Doyen.

Centenary of Volta's Invention of the Pile

THAT "the future belongs to electricity" was largely in evidence on May 20th, when His Majesty King Humbert opened the "Electric World's Show" at Como in honour of the invention of the pile by Alessandro Volta in the May of 1799. No effort has been wanting on the part of the great industrial centres of the Alta Italia or on that of the King's Government to heighten its attractions and to ensure its success, and when I mention its 11 galleries covering an area of 20 000 square metres and accommodating the specimen work of 1000 exhibitors, many of them foreign and nearly all of them of world wide fame, I may absolve myself, as the Scottish law phrase runs from "condescending on particulars." In these columns I drew attention to the medical interest of the exhibition—an interest dating from Galvani, Volta's great predecessor, and earned on through special therapeutic developments by Nobili, and still further and more widely by Matteucci, till "electricity in its application to the healing art" may as truly be called an "Italian contribution," as chemistry has been claimed by Professor Wurz as a "French science." There are other attractions to Como at this season especially, but these fall into the second line in presence of this wondrous display of human contrivance and energy, bequeathed by the century now nearing its end to its imminent successor and heir.

Protection of Women and Children in Factories and Mines

The deteriorating physique of the Italian labouring poor is traced to many causes—not least to the employment of women and children in works or industries unsuited to their age or sex. Not an hour too soon a Bill has been introduced into Parliament for the prevention of this abuse. It is now before me and a selection from its main provisions will indicate its salutary tenour—1. No woman and no child under 15 years of age shall be employed in factories served by more than 10 hands or provided with a "motor" or in excavations or in mines without authorisation of the Prefect acting on medical advice as to the health and capacity of the said woman or child. 2. By Royal Decree, inspired by the Consiglio Superiore di Sanità and by the Consiglio dell'Industria will be determined the dangerous and unhealthy works forbidden to children of both sexes under 15 years of age or to women in their minority, and there will also be determined those works in which they may be employed under specified conditions of age, including observance of a special time table of daily work and of technico-hygienic precautions also specified. 3. Children under 10 years of age shall be absolutely excluded from serving in industrial establishments, those under 14 years of age shall equally be excluded from work underground in excavations and mines and those under 12 years of age from work above ground. 4. Women in their minority shall be excluded from underground service. 5. Night-work carried on in industrial establishments, in excavations, and in mines is forbidden to children of both sexes who have not completed their fifteenth year and to women in their minority who when the Bill shall have become law are not found already employed. 6. Children of both sexes

800 trained nurses drawn from 20 training schools in Greater New York lately met in the ball room of the Waldorf Astoria to celebrate the twenty-fifth anniversary of the founding of the Bellevue Training School. These young women, dressed in the distinctive gird of blue sash, represented the increase in their number in the quarter of a century which has elapsed since the first class of five nurses graduated, marking a new departure in the medical history of this country. The history of the founding of the Bellevue Training School is as follows: 25 years ago there were no trained nurses in the United States! On Jan 28th, 1872, a number of women came to organize a committee, to visit the public hospitals of the city and county of New York and to report upon their condition to the State Board of Charities. As a result of this meeting 60 among the most intelligent women of the city daily passed hours in the wards of Bellevue carefully studying its conditions and considering the highest hospital authorities. As a consequence of this investigation it was decided that no permanent reform could be accomplished under the then existing system of nursing. The nurses were ignorant of the most elementary principles of the art of

¹ THE LANCET, Feb. 25th 1899 p. 534, 'The Mechanism of Electro-therapeutics.'

TYPHOID FEVER IN SOUTH WALES—At the meeting of the Langtyfach District Council held on May 16th Dr. Threlkeld Whithell made a special report upon the outbreak of typhoid fever at Pontardun (Glamorganshire). He stated that there were 20 cases occurring in 12 houses. The disease was imported from Carmarthenshire and its spread was attributed to a defective water supply and the absence of a proper drainage system. Dr. Whithell pointed out that these defective sanitary arrangements had been himself pointed out in annual reports by his predecessor and by the twenty-third annual meeting of this association was held at the Tenth of the London Temperance Hospital, the president of the British Medical Temperance Association—

The President, Professor Sims Woodhead, being in the chair. Dr Ridge, read the annual report which showed a considerable increase during the year, the members now being 494, the student associates 495, and the associates (Laymen) 4 Following the annual business meeting the ceremony of unveiling a large brass tablet to the memory of the late President, Sir B W Richardson, was performed by Mrs Sims Woodhead. Dr T Morton Rev Canon Barker, Mr A Y Nutt, Alderman Strong, Dr Cooper Key, Dr Ridge, Surgeon Major Poole, and Rev Dawson Burns The inscription on the tablet, which is embellished with a good likeness of Sir Benjamin Richardson in profile, is as follows : In memory of Sir Benjamin Ward Richardson, F.R.S., F.R.C.P., who died on Nov 21st, 1896, for 17 years the honoured and esteemed President of the British Medical Temperance Association and for four years Senior Doctor Physician to this hospital. This tablet is placed here by members of the association with the sympathy and by the kind permission of the Board of the London Temperance Hospital in affectionate remembrance of his invaluable services to the cause of temperance."

Letters regarding their inability to attend were received from the Presidents of the Royal Colleges of Physicians of London and Surgeons of England, from Sir Richard Thorneycroft, Dr Adler, the Chief Rabbi, Professor Michaelson, Mr V Horsley, Professor Simpson, and others

The amendments made in the Bill by the House of Lords were brought up and agreed to without debate. The measure now awaits the Royal Assent before becoming law.

Mr CHAKRABARTY asked the President of the Local Government Board whether he was aware that there was now no proper inspection of the carcasses of imported cattle, of which about 3000 were weekly slaughtered at Deptford and large numbers elsewhere and whether, in view of the fact that a large proportion of tuberculous and of cattle in cattle slaughtered and inspected for the detection of cerebro-pneumonia, he would arrange for a adequate staff to examine Mr CHAKRABARTY said he had made inquiries concerning the foreign cattle market at Deptford which was the only one specially referred to in the question and he was informed that in addition to the inspection of animals by two veterinary inspectors appointed by the Board of Agriculture there was a close inspection of the carcasses. This latter inspection was carried out by an inspector specially appointed by the Corporation of London who devoted his whole time to the duty and who acted under the supervision of a veterinary inspector of the Corporation and the superintendent of the market. He understood that the cases of tubercle in the cattle market were extremely rare—only two and occurred in the last 12 months.

Tuberculosis in Cattle

Feeble minded children.
SIR JOHN GOSART in reply to Mr. HASTY FRYER, said that the Bill dealing with feeble-minded children was in an advanced stage of preparation, but he was unable to say when it would be introduced.

[illegible]

Medical Men and the Compensation Act.

THURSDAY, MAY 18TH.

‘SNOKKOO DO HSDOH

the members of the typical English local authority. The medical officer of health of Brighton had reported that 25 per cent of general fever had resulted from the consumption of oysters procured at one of the places dealt with in Dr Bristow's report. Sir H. Broadbent and other great authorities in this and other countries had declared their conviction as to the communication of the disease by oyster consumption, and the Local Government had been urged by a powerful deputational representative of 28 of the largest towns in the kingdom to introduce some legislation to prohibit the removal of oysters for 10 days if they were covered with contamination. The owner had an appeal to the Local Government Board and the Local Government Board had power to act through the county council. The county council failed to do so. He had no wish to hurry the Bill through, but he hoped that their lordships would pass the second reading now and time would be allowed for the consideration of its provisions before the Committee stage.—The Bill was read a second time without debate.

nursing and the larger number were brought from Blackwell's Island, where they had been sent as vagrants or paupers or sometimes prisoners, and many could neither read nor write. Having decided that a reform in the nursing was imperative as a preliminary to reform in the general system a sub-committee was appointed to plan for a training school for nurses. The project was received with enthusiasm and \$22,385 were contributed to start the school. Through the influence of one of the Commissioners of the Board of Charities a reluctant consent was obtained from the board to allow nursing in five wards in Bellevue, for which the committee was to defray all the expense beyond that paid under the old system. In March a house was hired near the hospital for a home for the nurses and the committee engaged to take charge of the wards on May 1st. The school started its career amid a good deal of opposition, but it never wavered from its high ideals, and the principles accepted from Miss Nightingale have been faithfully followed, not only at Bellevue, but by all the schools subsequently founded up to the present time.

The Charities of the State of New York

The New York State Board of Charities reports that the statistics covering the fiscal year, collected by the board from the officers of charitable institutions, show that the public and private charities in this State which are subject to the supervision of, and which report to, the board had an annual income exceeding \$23,000,000, that they expended nearly \$22,000,000, and owned real and personal property conservatively estimated to be worth \$103,000,000, also that within the year in question they administered charitable assistance of various kinds, more or less costly, to a great army reported as numbering over 2,500,000 beneficiaries. These figures indicate the gigantic extent to which the charities of New York have grown and emphasise the necessity for the best and wisest methods of charitable administration in order that the poor may be most suitably relieved, while pauperism and its attendant evils, which constitute a dangerous and hurtful drain upon the industrial energy of the State, are diminished to the fullest extent practicable.

May 18th.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON—In May the following candidates passed in the subjects indicated—

Surgery—G. H. Bedford (Section II), Guy's Hospital; P. Cator, St. Bartholomew's Hospital; T. A. E. Fawcett (Section II), Leeds; A. Killick (Sections I and II), Cambridge and London Hospital; D. V. Lowndes (Section I), Westminster Hospital; A. Orme (Section I), London Hospital; V. S. Partridge (Section I), Charing cross Hospital; W. Slam (Section II), Birmingham; J. M. Twentyman, Cambridge and King's College Hospital; and R. Le G. Worsley (Section II), St. George's Hospital and Durham.

Medicine—E. L. D. Dawdney, King's College Hospital; R. F. Ellery (Section I), St. Bartholomew's Hospital; T. A. E. Fawcett (Section II), Leeds; A. Orme (Section I), London Hospital; O. C. Sibley, Middlesex Hospital; W. Slam (Section II), Birmingham; and H. E. Weston (Section I), St. George's Hospital.

Forensic Medicine—E. L. D. Dawdney, King's College Hospital; S. H. Longhurst, Guy's Hospital; A. Orme, London Hospital; O. C. Sibley, Middlesex Hospital; and H. E. Weston, St. George's Hospital.

Midwifery—T. Burdakin, University College Hospital; A. F. Carlyon, Middlesex Hospital; W. J. H. Hepworth, London Hospital; T. E. Holman, Guy's Hospital; H. N. Horton, Middlesex Hospital; A. Killick, Cambridge and London Hospital; W. Slam, Birmingham; and F. J. Waldmeyer, London Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise in medicine, surgery, and midwifery: E. L. D. Dawdney, T. A. E. Fawcett, S. H. Longhurst, W. Slam, J. M. Twentyman, and R. Le G. Worsley.

FOREIGN UNIVERSITY INTELLIGENCE—**Basil** Dr Otto Hildebrand of Berlin has been appointed to succeed the late Dr Sacius in the chair of Surgery. He is editor of the *Jahresberichte über die Fortschritte der Chirurgie*.—**Berlin** Dr Beckenhäuser of Würzburg has been appointed Assistant in the Institute for Infectious Diseases.—**Göttingen** Dr Erwin von Esmarch of Königsberg has been appointed Professor of Hygiene in succession to the late Dr Wolffhugel.—**Lemberg** Dr Franz Kosminski has been recognised as *privat-docent* of Midwifery and Gynecology.—**Münich** Dr Gudden has declined the invitation to succeed to Professor Rosenberger's chair of Surgery in Würzburg. Dr F. Weiland has been recognised as *privat-docent* of Physiology.—**Prague** (German University) Dr

Max Singer of Leipzig has been appointed Professor of Midwifery and Gynecology.—**Vienna** Dr Gustav Singer has been recognised as *privat-docent* in Internal Medicine.

ROYAL COLLEGE OF SURGEONS IN IRELAND FELLOWSHIP EXAMINATION—The following gentlemen having passed the necessary examination have been admitted Fellows of the College: Mr Denis Kennedy, Mr John Murray Redington, and Mr Lawder Thomas Whelan.—The following gentlemen have passed the primary part of the examinations for the Fellowship: Mr John F. L. Keegan, Mr Thomas J. Nicholl, Mr William G. T. Posnett, and Mr John White.

ROYAL ALBERT HOSPITAL, DEVONPORT—A meeting of the subscribers of this institution was held on May 15th to consider a proposal for enlarging and improving the hospital. It was eventually decided to erect a new nurses' home at a cost of £2200 and to provide isolation wards, consulting rooms for the medical staff, &c., at an estimated expenditure of about £1500. Sir John Jackson has promised £500 of this sum provided that £1500 more be raised within 12 months.

WEST CORNWALL WOMEN'S HOSPITAL, REDRUTH—The children's ward recently added to the West Cornwall Women's Hospital, Redruth, was formally opened by Mr Passmore Edwards on May 17th. The ward is to commemorate the Queen's Diamond Jubilee. The cost of the building has been £508, of which sum Mr Edwards has contributed £478. The furnishing of the ward amounted to £200 and this amount was given by Messrs S and T Trounson.

BIRKENHEAD MEDICAL SOCIETY—The annual meeting of this society was held on May 5th, Mr H. Nazeby Harrington, President, being in the chair. The annual report and treasurer's statement of accounts were read and passed. The following office-bearers were elected for the ensuing year: President, Mr H. Nazeby Harrington; Vice President, Dr Joseph Blood; Treasurer, Dr James Pinkerton; Secretary, Dr W. Leask, Prenton road, West; Librarian, Mr S. Wilkinson; Council, Mr A. H. Butcher, Dr W. R. Floyd, Mr J. H. Fardon, Dr R. O. Morris, and Dr L. D. Temple. The first monthly meeting of the new session will be held in October.

UNIVERSITY OF CAMBRIDGE—In connexion with the jubilee of Professor Sir George Stokes on June 2nd the honorary degree of Doctor of Science is to be conferred on the following distinguished physicists and mathematicians: Professor Cornu, Professor Darboux, Professor Kohlrausch, Professor Michelson, Professor Mittag-Leffler, Professor Quincke, and Professor Voigt.—The following have been appointed examiners for medical and surgical degrees: Medicine, Dr Lees, Dr Macalister, Dr S. Martin, and Dr Mitchell Bruce; Surgery, Mr Pitts; Professor Chiene, Professor Watson; Obstetrics, Mr Pitts; Professor Bird; Midwifery, Dr Oullingworth and Dr Barbour.—A contribution of £1000 has been made from the funds of the State Medicine Syndicate towards the cost of the new buildings for the Medical School and a grant of £50 in aid of the course of instruction in bacteriology provided for candidates for the Diploma in Public Health.—Mr W. Bateson will during next year deliver the course of lectures in Zoology as deputy for Professor Newton.

LITERARY INTELLIGENCE—The following are some of the announcements in Messrs Williams and Norgate's scientific book circular for May: "Die Spiele der Menschen" (Sports and Games), by K. Groos.—"Allgemeine Biologie," II. Vererbung und Entwicklung (General Biology. Second volume. Inheritance and Evolution), by Professor M. Kossowitz.—"Die Leitungsbahnen im Gehirn und Rückenmark" (Nerve Tracts of the Brain and Spinal Cord), by Professor W. von Bechterew.—"Traité des Maladies de l'Enfance" (Diseases of Children), by Dr Jules Comby.—"Atlas de Microbiologie," by Dr E. Macé.—"Ueber die Einbettung des menschlichen Eies und das früheste bisher bekannte menschliche Placentationsstadium" (The Embedding of the Human Ovum and the Earliest Stage hitherto known of the Human Placenta), by Dr H. Peters.—"Traité de Médecine," by Dr Bouchard and Dr Brissaud, second volume, Fevers.—"Das Füllen der Zähne mit Amalgam" (Amalgam Stoppings in Dentistry), by A. Witzel.—"Handbuch der Fleischbeschau" (Manual of Meat Inspection for Veterinary Surgeons, Medical Men, and Magistrates), by R. Ostertag.

"Allgemeine Biologie" II. Vererbung und Entwicklung (General Biology), by Professor M. Kossowitz. "Die Leitungsbahnen im Gehirn und Rückenmark" (Nerve Tracts of the Brain and Spinal Cord), by Professor W. von Bechterew. "Traité des Maladies de l'Enfance" (Diseases of Children), by Dr. Jules Comby. "Atlas de Microbiologie," by Dr. E. Macé. "Ueber die Einbettung des menschlichen Eies und das früheste bisher bekannte menschliche Placentationsstadium" (The Embedding of the Human Ovary and the Earliest Stage (hitherto known of the Human Placenta), by Dr. H. Peters. "Traité de Médecine," by Dr. Bouchard and Dr. Brissaud. "Das Füllen der Zähne mit second volume, Fevers," by Dr. H. Dentistry, by A. Witzel. "Handbuch der Fleischbeschau" (Manual of Meat Inspection for Veterinary Surgeons, Medical Men, and Magistrates), by R. Ostertag.

(German University) Dr

THE CLERGYMAN AND THE MEDICAL MAN

THE relations of the medical man to the clergyman should for obvious reasons be as close and as cordial as circumstances permit, and this we are glad to think is commonly the case. In an urban community they are necessarily much looser than they are in a village for in a town especially in a big city the medical man's patients will be distributed over the congregations of many denominations of clergy men, while the clergyman whatever his denomination or school of thought, will have in his congregation the patients of many different medical men. As a result there is not in town life the great bond between the medical practitioner and the clergyman which exists in parishes where their cure is largely identical. Still, though in a more indirect manner they can and do help each other immensely in the town, for many a hardworking man and woman although not communicative to both will be communicative to one or the other. To some the clergyman appeals more forcibly as a friend and counsellor and to some the medical man. If the clergyman and the medical man exchange confidences as far as the sanctity of the trust reposed in them allows each gains enormously in knowledge. The clergyman himself, not infrequently the largest almsgiver, is sure to be the recognised almoner of the neighbourhood. A few words to him from the medical man may serve to direct a flow of practical charity by which the health of the breadwinner may be preserved to his family. Similarly the medical man may learn from the clergyman details concerning the environment of his patients which from various motives had been concealed from him although of the first importance to his diagnosis and line of treatment. As long as this sort of co-operation has careful regard for the privileged nature of much that is told to the members of both professions it can only work for the public good.

In the country in the same way but more directly and certainly, the general practitioner is able to look to the clergyman's labours as a most valuable adjunct to his practical work. Not only is the domestic environment of the patient so well known to the country clergyman that he is able to impart pieces of information to the medical man that may be invaluable as suggestions for medical ministrations but his position towards his flock may enable him to give advice which would not always be accepted without resentment from a physician or surgeon. The public, especially the self respecting poor will generally do what they are told by the medical man if they think the advice good but if they do not see the rationale of the instructions which they have received they are apt to neglect them. Here is where the clergyman in the country may be particularly valuable to the medical man. The rustic community will follow his suggestions without understanding them. But the simple trust in the clergy man is abused not infrequently by persons who will not confine themselves to their proper sphere but who aspire to be medical men also. The prescribing clergyman is an interesting but not quite harmless survival from the middle ages when the community turned as naturally to the monk for simples as for prayers. Many of our readers have come across the prescribing clergyman and we have introduced him to their notice at different times in these columns. This is the man who shakes his head over the medical man's diagnosis and suggests that indigestion is really what he calls "gastric fever" or that the application which the patient has obtained from the regular source may well be discontinued that an ointment which clerical experience vouches to be most efficacious may be tried in its stead. Some clergymen have gone even further in the unorthodoxy of their therapeutics and have been found "colloguing with cancer-curers. If the practitioner in their neighbourhood objects to their interference with his clientele or points out the unwisdom of their proceedings they attempt to get him replaced by some more complacent medical man. This is done, among other ways by advertising a promising nucleus for sale or a house at a very low rent suitable for a medical man. These things are perfectly well known to us to occur and our columns show that they are quite familiar to the medical profession. But they form grave exceptions to the usual rules which govern the relations of the clergyman and the medical man who for the most part work excellently well together in their private capacities.

The close connexions between public health and public morals—the certainty that in a locality where the former is bad the latter can never be good—compel the clergyman and the medical man to take similar views in matters of State medicine and sanitation. On the great field of morality the paths of the sanitarian and the spiritual teacher are always in the same direction. To take one example only, the clergyman preaches against fornication while the medical officer of health prevents five persons of varying sexes from sleeping in one bed. Each works in his own way towards the same end and it is almost unknown for a difference of opinion in principle to exist, while in detail the agreement is generally complete. But a letter from a medical correspondent which we now append shows that clergymen are not always liberally minded in matters of public health:—

To the Editors of THE LANCET.

SIRS,—I ask for your help under the following circumstances. There is a widespread and serious epidemic of whooping-cough in this parish and neighbourhood several children have already died. The medical officer of health has used his powers and ordered the day schools to be closed and written more than once to the vicar of this parish urging him also to close his Sunday school. This the vicar declines to do, expressing the fear that the Nonconformist

bodies would "entice his children away." Upon it being represented to him that the Nonconformists also would probably promise to close their schools he replies that he cannot trust such promises. Consequently all the efforts of our medical officer of health and the inconvenience caused by the closing of the day schools are rendered of no effect.

May 24th

I am, Sirs, yours faithfully

SENEX

It has not often been our experience to record a more unfortunate piece of perversity than is displayed by this clergyman. He nullifies all the work of the medical officer of health undertaken to stop the spread of a disagreeable and very dangerous epidemic among the children of the neighbourhood and his conduct, judging from his words quoted by "Senex," has its origin in a particularly narrow bigotry. It is very unlikely that the Nonconformist schools of the district would keep their doors open in defiance of medical and public opinion when the board school and the Church school were closed but the frame of mind of the man who considers that the risk to the children of being captured by wicked Dissenters is graver than the risk of catching whooping-cough is one which we find it hard to imagine. Speaking with all respect for the Established Church and with full knowledge of the excellent work done by Church schools, we cannot but think that the children who attend the classes of this particular clergyman might obtain more discreet tuition elsewhere.

"A MEDICAL HERO"

To the Editors of THE LANCET

SIRS,—After reading the account in THE LANCET of May 13th entitled "A Medical Hero, my uncle, Dr James Nicol of Llandudno, with whom I live, told me of the following incident in his early medical career similar in details to that of Mr Burns—an incident which he had seldom or never spoken of before. About 60 years ago Dr Nicol (who is now 84 years of age and in comparatively fair health with the exception of chronic rheumatism in the back which prevents him from walking, but with intellect and memory perfectly unimpaired) was practising in Carnarvon in Lancashire and was called to see a Mrs. Smith, wife of a baker in that village, who was seriously ill and to whom he and another practitioner, a Dr Paterson, who is since dead, had to apply the stomach pump. Unfortunately it would not act and he and Dr Paterson turn by turn about, sucked out the contents of the woman's stomach, who was poisoned by some agent unknown the woman rallied for a time but eventually died.

I am, Sirs, yours faithfully

JAMES CHARLESWORTH.

May 15th, 1899

"SUPERFLUOUS HAIR."

To the Editors of THE LANCET

SIRS,—In answer to Mr Balmanno Squire's letter in THE LANCET of May 20th allow me to say that I have found that to reduce the hairs to a pale golden colour is sufficient to make them quite unnoticeable. The applications must be, as he remarks, thorough and repeated. The hair becomes very brittle and splits and breaks a good deal, but this I have looked upon as an advantage. As to irritation of the skin in my own experiments I have found that there is some but not more than quite disappears in a few hours with a good wash and a little vaseline. I always tell my patients to use an emollient application after using the lotion and have had no complaints on the subject.

I am, Sirs, yours faithfully

ERNEST M. N. WILLIAMS, M.D. Lond.

Newcastle-on Tyne, May 22nd, 1899.

To the Editors of THE LANCET

SIRS,—In regard to the above your correspondence column has been of the greatest value to me. May I through THE LANCET thank those who have replied to my letter on the subject and assure them that they have given me just the advice I wanted and have so done me a great service?

I am Sirs, yours faithfully,

M.D

May 18th, 1899

"THE FUND FOR THE RELIEF OF THE WIDOW OF THE LATE MR. H. KINGSLEY HUNTER, L.S.A."

To the Editors of THE LANCET

SIRS,—Kindly allow me to acknowledge the receipt of the following donations, making a total of £45 12s 9d.

I am, Sirs, yours faithfully

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager. Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

ABSTRACT OF AN

Oration on Medicine

A CENTURY OF MEDICINE IN AMERICA

Delivered at the Fifth Meeting of the American Medical Association, Columbus, Ohio, on June 7th, 1899.

By J. C. WILSON, M.D.,

OF KENTLAND, ILL.

The most wonderful century of the world's history draws to a close. Has medicine, that branch of human endeavour in which we are especially interested, kept pace with the times? Has the century done for it what it has done for other things? The question is not hard to answer. For medicine the changes of this year-hundred have been awakening from the sleep of ages. The work of the early anatomists, the great discovery of Harvey, Auenbrugger's laborious revelation, Jenner's patient investigation, were struggles in the slumber. The dawn of the century was auspicious. Vaccination was widely practised and its value everywhere recognized. Corneus rescued the Inventum Normi from oblivion. Lenses invented the stethoscope and discovered auscultation. The methods were practically complete, but it took 40 years and the influence of Skoda to make physical diagnosis a familiar art. The era of speculative medicine was fast drawing to a close. "Rads and "isms," arose, as they will arise from time to time among the half educated and the degenerate, but their influence has been with few exceptions short-lived and their reaction upon scientific medicine favourable. The microscope ceased to be a scientific toy and became an instrument of precision. New sciences ranged themselves as the handmaids of medicine. In 1858 Virchow issued the "Cellular Pathology as Based upon Physiological and Pathological Histology." It was but a step onward to experimental physiology, in truth the chemistry, and experimental therapeutics. In truth the "close and severe" methods had come and had come to stay. It was evident that these methods and these only could be successfully used in the search for truth. The fairy tales of science had become the everyday handbook of the medical man. We had fully entered upon the era of experimental medicine. Riber and chloroform anesthetics for operations and purposes robbed surgery of half its terrors and rendered possible operations previously impracticable. The germ theory of disease came into prominence as a working hypothesis. Lister made the astonishing discovery of surgical cleanliness, and early in the last quarter of the century the new surgery replaced the old. Marcellous changes, almost perfect and antiseptic technique has taken away the rest. There are those chiefly among the gentler sex, for whom surgery appears to have no terrors whatever. [Dr. Wilson then pointed out that chemical medicine did not progress so fast as other divisions of the subject until bacteriology came into being. Therapeutic science had been greatly improved, but the great lay in the field or preventive medicine. Dr. Wilson continued.]

The aim of modern medicine and the object of modern therapeutics is not so much to cure diseases as to prevent them. The human mind is now chiefly concerned in the study of origins. In every department of research whether the natural sciences, criticism, history even theology, the same method of inquiry is pursued. In the words of Allbutt, "the analytical method," is leading to a revolution in our conception of therapeutics as of all these other studies. A revolution which as yet we have not fully understood. This revolutionary conception is that death is not to be driven away by the apothecary, not by any cunning combination of drugs, but is to be prevented by the subtle strategies which consists in knowing all the moves of the game." And he predicts that "the medicine of the future will consist in setting out wits to nature, in recognizing that when evils are produced by the action of the heart in dilatation and hypertrophy, it is a matter of observation that what might be expected actually occurs. A striking example of this is afforded by the dilatation of the left ventricle under aortic regurgitation, the dilating force being brought to bear while the chamber is expanding. With the dilatation occurs also hypertrophy. All the blood which has fallen back into the ventricle is increased in proportion to the amount of regurgitation. Another instance of dilatation produced by dilatation upon it has been sufficiently dwelt upon in connection with the mitral regurgitation, the blood driven back into the auricle during the ventricular systole being returned into the ventricle during its diastole to its distension and compression. Commonly these two results are associated, though the proportions vary. Hypertrophy is apt to prevail when there is undue intension of blood during systole, dilatation when there is undue retention of blood during diastole. Hypertrophy is the more apparent when the exit of blood is impeded, dilatation when the entrance of blood is increased. The one affects the heart in systole the other in diastole. not the only mode of its production during diastole though as the chief and as one to which attention needs to be emphatically called.

Lastly, many constitutional causes, or causes acting on the system as a whole, are productive of cardiac dilatation, which condition may be spoken of without reference to particular causes, though it chiefly concerns the ventricles. Among these constitutional causes are such as affect the general nutrition, among which may be mentioned simple ulcer of the stomach particularly when associated with loss of blood, carcinoma of the same organ, anæmia (pernicious or of other kinds), diabetes, and possibly alcoholism. In the series of cases I have spoken of drunk occasionally presents itself as the antecedent of the dilatation, but it is to be doubted whether this is more than an accidental occurrence. Putting this question aside it is sufficiently evident that anæmia and exhaustion are efficient causes of cardiac dilatation though only of the minor degrees of it. It is to be presumed that the heart shares in the general debility and the muscle stretches from want of tone. To touch in retrospect upon the salient points connected with cardiac dilatation and hypertrophy, they are these. An obstacle presented to the contraction of any of the chambers of the heart is followed by hypertrophy and dilatation in different proportions. The thicker walls are more liable to hypertrophy, the thinner to dilatation. The ventricles are more liable to hypertrophy than the auricles, the left ventricle more than the right. Dilatation follows the reverse rule and is more prone to affect the auricles than the ventricles, the right ventricle more than the left. Hypertrophy of the left ventricle, often with little or no dilatation, ensures whether the impediment is consciously placed at the aortic exit or is remotely placed in the capillaries and is a matter of inference rather than of observation. When hindrance is opposed to the contraction of the right ventricle, which is usually by obstruction in the lungs, dilatation predominates, though hypertrophy is more or less apparent. Much dilatation, often combined with considerable hypertrophy, often affects the left auricle as the result of obstruction at the mitral orifice as the result of stenosis. All these causes of hypertrophy and dilatation act by increasing the intra-cardiac pressure during the process of contraction. But there is another process which I particularly wish to insist upon which is especially productive of dilatation—that is, increase of intra-cardiac pressure during relaxation or diastole. Pressure exerted at this time, while the walls are in the act of expansion and the muscle presents a minimum of resistance, would seem to be well suited to cause stretching and it is a matter of observation that what might be expected actually occurs. A striking example of this is afforded by the dilatation of the left ventricle under aortic regurgitation, the dilating force being brought to bear while the chamber is expanding. With the dilatation occurs also hypertrophy. All the blood which has fallen back into the ventricle is increased in proportion to the amount of regurgitation. Another instance of dilatation produced by dilatation upon it has been sufficiently dwelt upon in connection with the mitral regurgitation, the blood driven back into the auricle during the ventricular systole being returned into the ventricle during its diastole to its distension and compression. Commonly these two results are associated, though the proportions vary. Hypertrophy is apt to prevail when there is undue intension of blood during systole, dilatation when there is undue retention of blood during diastole. Hypertrophy is the more apparent when the exit of blood is impeded, dilatation when the entrance of blood is increased. The one affects the heart in systole the other in diastole. not the only mode of its production during diastole though as the chief and as one to which attention needs to be emphatically called.

At a meeting of the Llandaff and Dinas Powys Rural District Council held on May 30th the clerk reported that the Glamorganshire County Council had written stating that regard to the proposed isolation hospital a compulsory order would be issued. After some discussion the matter was referred to the committee.

We wish to acknowledge the courtesy of the editor of the *Philadelphia Medical Journal* who has given us the opportunity of publishing this address.

of dilatation, if the association be more than accidental it must be attributed to deterioration of the muscular fibre produced by the drink.

Dilatation of the left auricle may be conveniently considered in juxtaposition to that of the ventricle. The cause of dilatation of the left auricle is generally disease of the mitral valve which may be either obstructive or regurgitant. The dilatation is most remarkable with stenosis, the extreme narrowing of the auricular exit which some times exists opposing resistance to the emptying of the cavity and occasioning repletion, dilatation, and hypertrophy. The abnormal pressure within the cavity, be it observed, is during its contraction, and hypertrophy of the muscular tissue together with dilatation is a conspicuous result. Mitral regurgitation acts differently, the pressure is here brought to bear within the auricle during its expansion with the result of great dilatation and comparatively little hypertrophy.

To pass now to the right side, the right ventricle is dilated with greater frequency than the left but usually to a less degree. Disease of the valves, the chief source of the greater degrees of dilatation, prevails less on the right side than on the left. Dilatation of the right ventricle is due in an overwhelming majority of instances to obstruction of the pulmonary circulation by diseases proper to the respiratory organs. I find that in 86 cases in which the only noticeable dilatation was of the right ventricle this was attributed in 62 to obstruction in the lungs or air passages. This number included instances of phthisis, emphysema, bronchiectasis, pneumonia, broncho pneumonia, bronchitis, empyema, pleurisy, diphtheria, and other forms of laryngeal and tracheal obstruction. In one instance it was attributed to tetanus. In all these cases the dilatation was slight. The greater degrees of it were caused by disease of the valves mostly of the left side of the heart and of the mitral valve more often than of the aortic. Mitral regurgitation and mitral obstruction are both frequent in this relation, regurgitation with a slight preponderance. To look for a moment at the action of mitral regurgitation in dilating the right ventricle it is obvious that the regurgitant current overloads the left auricle and the pulmonary veins during the ventricular systole simultaneously with the normal discharge from the right ventricle into the pulmonary artery. The two currents conflict, the emptying of the right ventricle is hindered, and dilatation ensues by abnormal pressure within this cavity during systole. With regard to mitral stenosis the same result is in the end produced. The left auricle, unable to empty itself, remains permanently occupied and thus opposes a difficulty to the relief of the pulmonary veins and of the right ventricle. Aortic regurgitation is also a recognisable cause of dilatation of the right ventricle. The way in which it acts is clear. The repletion of the left ventricle in diastole hinders the discharge by the pulmonary veins, impedes the current in the pulmonary artery, and so places difficulty in the way of the closure of the right ventricle. Disease of the right valves is insignificant as a cause of change in the right ventricle in comparison with disease of the left valves. Tricuspid regurgitation is recognisable, though infrequently, as a cause of dilatation of this cavity. It acts, as does mitral regurgitation upon the left ventricle, by creating repletion during diastole. Dilatation of the right auricle frequently accompanies that of the right ventricle and may be due to any condition which impedes the emptying of that cavity. These conditions I need not recapitulate. The varieties of pulmonary obstruction, particularly if chronic, and disease of the left valves, especially of the mitral, are the most frequent causes. Mitral stenosis gives rise to great dilatation of both auricles, the left is often hypertrophied as well, with the right dilatation is more prominent. The *modus operandi* of the latter change is obviously the loading of the pulmonary circulation and the consequent difficulty in the discharge of the right cavities.

So much for dilatation of each cavity taken separately. There are many states in which both ventricles or all the four chambers are together affected. Multiple or general dilatation often depends on complicated valve disease, sometimes on disease limited to one valve, more especially if that valve present a double imperfection, and sometimes on an apparently simple lesion, such as that which occasions mitral regurgitation. When the valve lesions are multiplex it is easy to understand from what has been already put forth that the dilatation may be multiplex also. In the case

of simple mitral regurgitation it is equally easy to see how this may affect several of, or all of, the cavities. The mitral reflux necessarily dilates the left auricle. The reflux in returning dilates the left ventricle. The repletion of the left auricle opposes the discharge from the right ventricle with consequent dilatation of the right side.

Mitral stenosis in theory should be attended with the opposite state of the left ventricle to that which attends mitral regurgitation. With the lessened admission of blood the cavity should shrink upon its diminished contents and become atrophied with the diminished blood pressure within it. In rare instances this is so, but these are exceptions rather than the rule. Mitral stenosis is almost invariably attended with regurgitation and the consequent changes are thus complicated. Beside lesions of valves general dilatation, or dilatation affecting both sides of the heart, may be produced by aneurysm of the arch of the aorta, more rarely by pericardial adhesions and commonly by many conditions of pulmonary obstruction. With regard to aneurysm it is recognised that the disease *per se* has little effect in causing cardiac hypertrophy, though often associated with other causes to which it is due, but the cases to which I have appealed show that dilatation sometimes presents itself with aneurysm apparently as its consequence, and that the dilatation may affect both ventricles. It is to be suggested that the dilatation of the left ventricle is first produced by the aortic obstruction and that mitral incompetence follows though the valve segments are healthy, and subsequently the changes in the right side which mitral regurgitation produces. It is not easy to isolate the action of pericarditis as a cause of cardiac dilatation or hypertrophy since pericardial inflammation is so constantly associated with valvular inflammation that we may doubt how much to attribute to each. With pericardial adhesions it is obvious that resistance is opposed to the movement of the walls and increased work imposed which may lead to hypertrophy.

From the cases which I have collected it seems clear that dilatation of both sides of the heart, often together with hypertrophy, is concurrent with many conditions of respiratory embarrassment, among which may be mentioned bronchitis and broncho-pneumonia, emphysema, diphtheria, and diphtheritic paralysis. It is obvious that such conditions obstruct the pulmonary circulation, hinder the discharge from the right ventricle, and thus cause its dilatation, but how do they affect the left ventricle? The facts suggest that engorgement of the right side of the heart acts backwards by retarding the venous circulation, produces stagnation in the systemic capillaries, then of the systemic arteries, and eventually tells upon the left ventricle. I could adduce a case in which enormous dilatation and hypertrophy of both ventricles, the heart weighing 32 ounces, presented no other obvious cause than fibrosis of the lung together with bronchiectasis. I cannot but think it probable that in this case the fibrosis was more general than is represented and the cardiac hypertrophy not simply due to the state of the lung.

Hitherto I have been considering causes of dilatation of which the mechanical origin is obvious in valvular imperfection, or such as depend on obstructions in the pulmonary circulation which, though less obvious, are scarcely less evident. I now proceed to others which depend on inferential obstructions, on changes in the tissue of the heart itself, or on constitutional conditions. The most frequent of all these is renal disease. I need not revert to the frequency of hypertrophy and dilatation of the left ventricle from this cause, but may add that in most cases the right ventricle is also involved, though to a much less extent. As between hypertrophy and dilatation though hypertrophy generally with some attendant dilatation is far more common with renal disease than dilatation alone, yet, dilatation is sometimes conspicuous particularly with the less protracted forms such as result in the large white kidney of nephritis and the contracted white kidney of the same origin.

Dilatation of one or both ventricles with or without the participation of the auricles is sometimes due to fatty or fibroid changes in the walls, but these causes are numerically insignificant as compared with other cardiac and constitutional states. Of 259 cases of ventricular dilatation I found only nine where obvious muscular change without valvular lesions was recognised as giving rise to it, though it is of course likely that muscular changes may have been present in some cases where they escaped notice.

organiser this association has had abundant proof, and Report—a life of matchless energy and devotion to the widest human interests, whose rare gifts as a physician and abilities as a teacher, whose civic pride and high patriotism, will place him, when the picturesque history of our times come to be written, among the great Americans and in the foremost rank of the citizens of that Commonwealth which reverently claims Franklin and Bush as her own.

It is not wholly to the case with which knowledge is spread nor to the great men of the profession that we owe the advanced position of medicine in America to-day. Important as each of those factors is, it may well be questioned whether their combined influence could have impressed upon the art of medicine the pre-eminence and which the profession of our country stands pre-eminently and which is at once of the greatest practical value and of the noblest promises for the future. That pre-eminence is the prerogative of high ideals. All kinds of men engage in the pursuit of medicine from all kinds of motives. But to the necessity of a livelihood and to personal ambition the American medical man adds, and very often in the absence of those be cherished but only indirectly bearing upon his vantage medicine, or schemes for the welfare of the poor, or better literature, or medical libraries, or for himself a broader knowledge and a keener art, or toward his fellow man a greater gift of usefulness. Such thoughts are seldom in his soul and recreation in his hours of leisure, with widening opportunities and high examples he must have something more than his everyday work. Without some cherished ideal he cannot be content. It is wholesome mental refreshment is peculiarly American. It comes of our physical restlessness. We lack repose because we abound in energy. Contentment means conservatism and conservatism points in the direction of stagnation. When we speak of stagnation we think of localities, of isolation, of the tendency which distinguishes American medicine. It is essentially opposed to isolation, to individualism. It exists in the direction of a higher, more complete, and more specialised organisation of the profession. It is this tendency which has made the general fount of knowledge accessible to all members of the profession who care to share it—which has given to the independent worker, in what-ever department, an upbuilding sense of companionship, of community or interest, of sympathy in a common cause. It is this which has brought into the life of the toiling practitioner in the remotest of his everyday duties and cares a satisfying consciousness of personal dignity and power.

To the physicians of Northern New Jersey must be ascribed the credit of having made the earliest attempt to promote the interests of the profession by means of organisation. In the year 1768 a meeting was held at New Brunswick attended by delegates from all parts of the State and a permanent organization effected. The objects of the association as set forth in the preamble to the constitution were "mutual improvement, the advancement of the profession, the promotion of the public good, and the cultivation of harmony and friendship among the members." This society held regular meetings twice a year until that memorable meeting of May 7th, 1847, at which, by the election of Nathaniel Chapman as President, Jonathan Knight Alexander H. Stevens, James Moultrie and A. H. Buchanan, Vice-Presidents, Alfred Shill and J. H. W. Dunbar secretaries, and Isaac Hays, treasurer, were finally carried into effect the organisation of the American Medical Association. [After a few remarks upon the importance of such an organization Dr. Wilson proceeded.]

In general as regards the requirements for a degree the American Medical Association should, in my opinion, exert an influence to secure uniformity in the requirements for admission a systematic graded course with uniform tests at the end of each year, and uniform requirements for graduation. With reference to written examinations the question of that system can be carried out at many of the colleges, at West Point and Annapolis and at the University of Virginia who not in all our medical schools? The general adoption would go far in determining a high standard of personal and professional honour. It should exert its influence also to secure General uniformity in the examinations for the licence

to practise among the States and a general reciprocity among those boards by which the licence may be transferred. It should strongly exert its influence in the direction of the regulation of the specialties and the requirements of evidence of clinical experience in general medicine as pre-requisite to the practice of them. It should exert its influence in the matter of expert testimony in courts of justice. This subject is a growing scandal. A change of practice is urgently necessary both in the interests of justice and that of the medical profession. It should exert its influence to secure such legal enactments in the several States as will protect the people from the various forms of unorganized and organized quackery and to the end that no licence to practise medicine in any of the branches shall be granted to any applicant until such applicant has successfully passed an examination in anatomy, physiology, pathology, surgery, midwifery, and the diagnosis of diseases, and that a stringent penalty shall be enforced against all persons who seek to practise upon the sick, injured, or deformed, by any means or upon any pretext whatever except in the case of accident or emergency, and then only for the purpose of immediate relief and assistance. It should exert its influence to build up in the secular and religious press of the country a proper sense of responsibility in regard to lewd, indecent, and criminal advertisements thinly disguised as medical and against the appearance in such publications and in certain so-called medical journals of advertisements of nostrums and cures. It should obtain uniform divorce laws for the whole country and do away with the legal enormity of a man and woman being legally married in any State and living in adultery so soon as they have crossed its borders. The question is primarily one of morals, but it is also one of health. It should exert its influence strongly in favour of proper rearrangement of the status of military and naval medical officers to the end that the efficiency of those branches of the public service may be increased and the recompense and the rank of the medical officers properly adjusted. It should exert its influence to secure the dual appointment of surgeons and physicians to regiments and posts, since the work of the two is complementary and cannot in the present state of the art of medicine be properly performed in all its details by any one man, especially in active service, also to secure the establishment of clinical laboratories in connection with the military hospitals in the tropical stations with the detail of medical officers especially fitted by training and experience for the investigation of tropical diseases and conditions. It should exert its influence to secure a national quarantine service with full jurisdiction over the seaboard and the lake borders and over internal regions affected with general epidemics or endemic conditions not amenable to the control of the local authorities. It should exert its influence to secure the appointment of a secretarieship of Public Medicine, the portfolio of which should be assigned to a medical man, to the end that the President may be promptly and authoritatively advised concerning technical questions of vital importance to the welfare of the nation.

To many of you these suggestions seem utopian and impracticable. Not so. If we earnestly desire them they will come to pass. Their fulfilment rests with you and in your hands is the power of an organized profession.

CHRISTINA CLINICAL SOCIETY.—The second annual dinner of this young society was held at the Canteen Restaurant on June 3rd, the President, Mr. J. Foster Palmer being in the chair. A numerous company of members and their friends attended and a most enjoyable evening was spent. After the several loyal toasts the President, Mr. H. O. C. Gibbs replied. The toast of "The Chelsea Clinical Society" gave a short review of the work done by the society during the past year, referring more especially to the debate on Dr. O. C. Gibbs' report of which appeared in our columns. The toast of "The President" was replied calling attention to the advantages derived from medical societies in promoting unity amongst professional men. The usual toasts of "The Visitors," "The President" (proposed by Dr. W. Ewart), and "The Officers of the Society" followed and the social qualities of the meeting were enhanced by music and recitations.

have befallen us there is no counsel, and that in the simple beginnings of things are the time and place to detect where stealthy nature, atom by atom, builds and unbuilds, feeds us or poisons us." Modern medicine is no longer content with trying to make some salvage out of the wreckage of disease, but is earnestly seeking for measures by which the storm can be avoided, the channels deepened, and the rocks upon which high hopes are wrecked beacons.

All that is best in the older medicine is to be found in the new, but the new is something essentially different. The old was an art based upon empiricism, relying largely upon so-called specifics and not altogether scornful of charms and magic. The new is an art based upon a group of correlated sciences and deriving its power from the forces of nature. But the new is the outcome of the old, for the empiric method is the gateway to science and the accumulation of facts necessarily precedes generalisations in regard to them.

It is of interest to note the position of the United States in regard to modern medicine. It is no long time since our people were pushing westward over the wilderness and a famous poet and story writer has accused us of being some centuries behind Europe in learning and manners. Railroads and the telegraph are great civilisers, and the Postal Union a wonderful teacher. There is no wilderness now except that beyond the seas and "a few centuries" is a figure of speech. In medicine the world's knowledge is ours. The latest work of investigators in every field of research and in every country is quickly before us and we give something in return. Laveran discovered for us the malarial parasite and Marchiafava, Golgi, and others of the Italian school elaborated his observations, but an American, the late Professor J. K. Mitchell, had anticipated the discovery, being "the first to approach in a scientific spirit the nature of infective disease and particularly in malarial fever," and Laveran's observations were early confirmed on this side the Atlantic by Councilman, Osler, Thayer, and others. Roux and Behring gave to the world the treatment of diphtheria by antitoxin serum but the uncertainties concerning its efficacy were settled by Welch's analysis of the statistics and the two collective investigations of the American Pediatric Society. Ernest Brand devised the method of treating enteric fever by systematic cold bathing and showed that by it the mortality is, out in half, but it remained for American practitioners to demonstrate that the plan is not only feasible in hospitals, but also in private practice. Macowen and Horsley showed that cerebral tumours could not only be definitely localised, but also that they could be successfully removed, but cranial surgery was carried to its full development and a perfect technic laid down by Keen. Here and there we have given more than we have received. We recall the contributions to neurology and especially the successful treatment of neurasthenia and hysteria by Mitchell, the second in the line of an illustrious medical family, and speak of intubation in grateful memory of the gentle O. Dwyer, and in surgery we are reminded that the New World has given something to the Old, by the work of Sehn, Murphy, Richardson, McBurney, my colleague Deaver, and by that in earlier times of the clear-minded Grosses father and son, the Brothers Atlee, and the heroic McDowell. The instances of accord, response, co-endeavour between the workers in medicine on the opposite shores of the Atlantic could be indefinitely multiplied.

In the field of literature the conditions are the same. On the one hand the great weeklies of Berlin and Munich, *THE LANCET*, and the *British Medical Journal*, on the other hand the journals of Boston and New York, the *Philadelphia Medical Journal* and the *Journal of the American Medical Association*. It is impossible to speak here of individual monographs and treatises. But against such store-houses of medical lore as Ziemssen's *Encyclopedia* and Nothnagel in Germany, and Allbutt's *System* in England, may we not set Pepper's *System* and that of Loomis and the Twentieth Century Practice? It is an exchange of courtesies, of products. It is a well balanced reciprocity.

If America is a little behind in original research she is very alert in the application of that which is serviceable. If her investigators are less "laborious" and less numerous her practitioners excel in adaptability, tact, and skill. Meetings of national societies such as this and the national and international congresses are a strong force in the process of unification. One of the finest things in the medicine of our day is its solidarity. In the institutions where medicine is taught and in the organisation of the instruction we are making hopeful advancement. Much remains to be

done, but the defects are chiefly in the direction of want of uniformity of requirement and of full co-operation among the several States and are in a fair way of correction. An open handed philanthropy has scattered among the great centres of population from the Atlantic seaboard to the Pacific slope commodious, well appointed, fully equipped hospitals, not at all inferior to the great hospitals of the Old World. Their foundations are less ancient, as must be in a young country, but their spirit is more plastic. Traditions are fine but they sometimes fetter thought. To the noble-hearted non-medical managers of these institutions it is clearer than ever before that while the care of the sick poor is the primary object it is by no means the whole object of a modern hospital. The instruction of the student, the training of the medical man, clinical and pathologic research, the accumulation of facts for immediate or future use in scientific medicine are secondary functions of essential importance. So it has come to pass that to the non-medical mind, as it has long been to the medical, the necessity of the set of laboratories, pathologic, bacteriologic, clinical, is paramount. The correlative fact that the number of the staff must be much greater in proportion to the number of the patients than formerly has also become apparent. So that by a process of evolution hospitals are taking a much larger part in the education of the medical man than ever before, even those in which a very conservative management is hostile to clinical instruction.

It is clear then not only that medicine has kept pace with the progress of the times, nay, more, that it has made advances even more wonderful than many other departments of thought, but also that in America the position of the profession compares favourably with that of any other country. Medicine with us is to-day one with the medicine of the world. Yet it is little more than 100 years since the country was without a medical profession in the sense in which the term is now used and was then used in the Old World. This is not the time nor the place to rehearse the history of medicine in the colonies. The subject is set forth in great detail in the writings of Beck, Clark, Bigelow, Ruschenberger, N. S. Davis, and Billings.

[Dr Wilson here mentioned how the first enactment regulating the practice of medicine in the American colonies was passed in New York in 1760. The medical faculty of Philadelphia was established after the revolutionary war in 1788, although the Medical School had commenced in 1785. Dr Wilson continued.]

It must be admitted that the rapid strides with which the medicine of the younger country has overtaken and is now keeping pace with the medicine of the world were largely due to the facilities of intercommunication that constitute one of the peculiarities of modern life. Knowledge travels far and fast. It has the wings of the light. It must be also conceded that such progress has been aided and accentuated in a remarkable manner by the master spirits who, from time to time appearing upon the scene, seem to be charged with an especial mission and whose presence marks eras in the course of human events. Easily and by far the greatest of these, *primus inter pares*, is Rush. Others among his contemporaries I have already referred to. Nor do I intend to enumerate a complete list. Permit me to name one here and there, sometimes a group, as fine examples of medical men who, to say the least, are not commonplace. It is easy for one who has read our medical history to recall John Morgan, Redman, Hosack, Drake (who wrote the "Diseases of the Mississippi Valley"), or that coterie of Louis' pupils, including Shattuck, Oliver Wendell Holmes, and Gerhard, who brought back from France physical diagnosis, the distinctions among the fevers, and reasonable methods of clinical work, Jackson and Morton, and the controversies concerning ether, the group of men who, representing others it is true, really effected the organisation of the American Medical Association, whose officers were Knight, Leil, Delafeld, Arnold, and Stillé. Jones of New Orleans is to be mentioned among those whose writings have powerfully influenced the trend of medical thought in the United States, and Flint and Otis and Woodward, to whose industry and ability we owe the "Medical and Surgical History of the War of the Rebellion", and Billings and Fletcher who have given to the medical world the "Index Catalogue of the Library of the Surgeon General's Office of the United States Army" and that unique and most useful of current medical publications, the "Index Medicus." I mention with that emotion with which we speak of a companion newly passed away John B. Hamilton, of whose skill as an

EXPERIMENT IV—Warm Bath, 15 Minutes, Temperature 88° C

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	60	120	135	17
After	60	120	135	15

EXPERIMENT V—Sit Bath, Running, 10 Minutes at 87° C, Cooled at Finish to 80° C

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	66	160	135	17
After	64	125	85	12

In each of these three experiments there is a fall in arterial pressure and a fall in venous pressure, the variation in pulse rate remaining practically constant. If we contrast the percentage fall of arterial pressure with the percentage fall of venous pressure we find that in the first two cases the fall in venous pressure is in greater proportion than the fall in arterial pressure. A diminished output of the heart would tend to lead to a rise in venous pressure, the heart would tend to lead to a rise in venous pressure, therefore, as we know that heat produces local vasodilatation, these results are best explained as due in the first place to peripheral dilatation of the arteries, and secondly to increased capacity of the vascular system resulting from that dilatation. It should be stated with regard to Experiment V that before the bath the subject felt somewhat chilly, hence his arterial pressure was considerably above this normal and the fall that occurred was greater than would otherwise have been the case.

Heat in the form of hot dry air, applied generally, has a similar effect in lowering the maximum and mean arterial pressures, but it relatively raises the venous pressure. Not infrequently an absolute rise of venous pressure takes place, though in our experiments the relative rise was more commonly observed (Experiment VI).

EXPERIMENT VI—Turkish Bath, General Dry Heat

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	70	200	135	25
After seven min. in hot steam at 99° C	120	155	100	20
In cooling room after shampoo—	74	170	115	20
After 20 min. in second room at 77° C	110	140	80	17
In cooling room after shampoo—	70	165	110	20

Here the fall in arterial pressure after exposure to high temperature is considerable, while the fall in venous pressure is insignificant. These changes are accompanied by a marked increase in the pulse rate which is nearly doubled. In the light of Stewart's researches on the output of the heart the diminished output that accompanies a great increase in the frequency of the pulse may share in the production of the lowered arterial pressure, for he finds that in general when the pulse rate increases considerably the output per heart beat diminishes while the output per second may or may not alter, but is usually diminished too although not in the same proportion as the output per beat. Arterial relaxation also takes place and both factors act in the same direction and combine to lower the arterial pressure.

EXPERIMENT VII—Russian Bath, General Moist Heat; 15 Minutes at 41° C

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	64	155	107	20
After bath and douche two minutes, cooled to 21° C	60	150	102	17
Before	72	175	130	25
After bath and douche, cooled to 30° C	70	160	115	25

The needle douche administered after the bath was taken at 21° C than by the second (30° C), the resulting fall in arterial pressure is therefore less in the former case than in the latter, though not entirely, abolished by the raising tendency of the cold and perspiration.

Effect of perspiration—Experiments I and IV show the effect of cold and warm immersion baths in raising and lowering respectively the arterial pressure. Experiment II shows the effect of perspiration added to that of cold and thereby greatly increasing the rise obtained. To ascertain further the effect of perspiration a warm needle bath at 38° C was given with the object of seeing whether the raising effect of perspiration would overshadow the lowering effect of the temperature. This was found to be the case, the result being a slight rise in arterial pressure (Experiment VIII). Contrary to what happened in Experiment I, the venous pressure rose, which tends to show that the peripheral resistance was not increased and that therefore the rise in arterial pressure could not be attributed to this cause. Probably, as in the case of the cold needle bath, perspiration leads to an increased output of the heart and this, acting with a diminished peripheral resistance due to the heat, would explain the rise observed in venous pressure. 10 minutes after the bath the mean pressure fell to 105 mm. Hg in consequence of the subject having been wrapped up a warm towel.

EXPERIMENT VIII—Warm Needle at 38° C, Three Minutes

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	72	140	115	15
After	72	145	120	20

Heat and cold alternating—In the alternating needle bath or Scotch douche, where the temperature is made to rapidly oscillate between warm and cold the net result is a rise in arterial pressure with a slight fall in venous pressure (Experiment IX).

EXPERIMENT IX—Alternating Needle Bath, Six Minutes Temperature from 37° to 27° C

	Pulse-rate	Arterial pressure		Venous pressure
		mm. Hg.	Mean	
Before	60	175	130	25
After	68	190	145	22

THE EFFECT OF BATHS, MASSAGE, AND EXERCISE ON THE BLOOD-PRESSURE

By WILFRID EDGECOMBE, M D LOND, F R O S ENG,

AND

WILLIAM BAIN, M D DURH, M R O P LOND

Mode of observation—The recent appearance of new instruments for the determination of blood pressure in the human subject has enabled us to make the following series of observations on the effects of baths, massage, and exercise on the arterial and venous blood pressure. The hemodynamometer of Oliver and the pulse-pressure manometer of Hill were carefully compared and found to read alike, but as the former instrument proved to be rather easier of manipulation and possesses a much wider scale it was used throughout. Both maximum and mean arterial pressures were recorded and the venous pressure was taken according to the method described by Oliver.¹ For arterial pressure the radial artery was employed, the subjects being in the recumbent posture except where otherwise stated, with the arm extended on a level with the heart. For venous pressure the veins on the dorsum of the hand or wrist were taken in some subjects, in others those of the forearm, with the same precautions to eliminate the effect of gravity. 10 subjects in all were experimented upon, their ages ranging from 20 years to 60 years. They included marked examples of both low and high pressure. Most of the results were confirmed by repeated observation. In the few instances in which this was not done confirmation did not appear to be necessary.

General considerations—At the outset, before proceeding to discuss the results, it is perhaps expedient to refer briefly to the factors which govern the production and maintenance of blood pressure and to point out how far they can be estimated by the instrument used. The chief factors concerned are the output of the heart, the extensibility and elasticity of the arterial walls, and the peripheral resistance. None of these can be directly measured by the instrument. The maximum arterial pressure, as measured by the instrument, being that force which just prevents the passage of blood along the artery, is a force equal to the sum of the true maximum arterial pressure and the forces requisite to produce distortion of the tissues and artery. The latter factors we are unable to measure, though they probably remain constant for each individual during any short series of observations. The mean arterial pressure is taken as the mean pressure recorded by the instrument when the indicator gives its maximum excursion. The difference between the maximum and mean arterial pressures as thus recorded can serve as an indication of the force with which the blood is discharged if we suppose the rate of discharge to remain the same during the time occupied by the observation. When the rate of working of the heart varies during the period of observation the indication is less reliable.

The two variable factors determining changes in the mean arterial pressure during any short series of observations are the output of the heart and the degree of constriction of the peripheral arterioles, consequently a fall in mean arterial pressure may be caused by a dilatation of the peripheral arterioles or by a diminished output of the heart, the latter being due to a slowing of the rate of working or to a diminished output of blood per beat. A rise in mean arterial pressure will be due to the same factors working in the opposite direction and a variation in mean pressure can also be caused by variations in opposite directions but to unequal extents of the same two factors.

From the measurement of the venous pressure as recorded by the instrument we can to some extent infer the state of the peripheral resistance, for a constriction or dilatation of the arterioles will be accompanied by a fall or rise respectively of venous pressure, provided the other factors remain constant. Hence variations in venous pressure would serve as a measure of the degree of peripheral resistance were the other factors to remain the same.

BATHS

Cold—The effect of the cold bath of plain water is to raise the arterial pressures, both maximum and mean, and to lower the venous pressure (see Experiment I). As in this

EXPERIMENT I—Cold Bath, two Minutes at 19° C

	Pulse-rate.	Arterial pressure, mm. Hg.		Venous pressure mm. Hg
		Maximum.	Mean.	
Before	70	190	130	25
After	72	210	150	10
10 minutes after	70	185	125	25

instance the rise in arterial pressure is accompanied by a fall in venous pressure we should conclude that this is caused by a peripheral constriction. The other way the result could be produced—viz., by increased output of the heart—does not seem to be indicated by any variation in the pulse-rate. That the conclusion which we draw from this observation is correct is shown by other experiments specially designed to determine the influence of cold applied to the skin. The rise in pressure obtained is of brief duration in normal subjects, for when reaction sets in the arterial pressure falls slightly below its original level, presumably from arteriolar dilatation, and the venous pressure rises to its initial height, relatively, therefore, to the arterial pressure it is slightly higher than before the bath.

If to cold the effect of percussion be added in the form of a strong needle-douche applied simultaneously to the whole surface of the body the arterial pressure becomes raised to a greater extent than with cold alone. Experiment II gives the details of the results obtained, the subject having a low initial blood pressure.

EXPERIMENT II—Strong Needle Bath begun at 57° C and rapidly cooled down to 16° C, Twice, two minutes

	Pulse-rate.	Arterial pressure, mm. Hg.		Venous pressure mm. Hg
		Maximum	Mean	
Before	64	115	85	15
After	72	150	115	10

In this case there is a considerable rise in arterial pressure with a small fall in venous pressure and a distinct increase in the pulse rate. These changes are best explained by supposing them to be due to a moderate amount of peripheral constriction accompanied by an increase in the output of the heart. That we are correct in supposing that the latter factor is at work in this instance is borne out by the results of Stewart's² experiments upon the output of the heart. He showed that a moderate increase in the pulse-rate usually corresponded to an increase in the output per second, a result which might explain the whole or part of the rise observed in this experiment. That peripheral constriction also plays a part in producing this rise is indicated by the result of the preceding experiment and by the fact that a simultaneous fall in venous pressure occurs.

Heat—The effect of warm baths of plain water, on the other hand, is to reduce the arterial pressure to an extent roughly proportionate to the increase of temperature (see Experiments III, IV, and V).

EXPERIMENT III—Hot Bath 10 Minutes, Temperature 43° C

	Pulse-rate	Arterial pressure mm. Hg		Venous pressure mm Hg
		Maximum.	Mean.	
Before	62	185	130	20
After	64	170	117	15

EXPERIMENT XVIII—Series of Air Douche, Temperature 37-38° C

Pulse-rate	Arterial pressure, mm. Hg.		Venous pressure, mm. Hg.
	Maximum	Mean	
Before (sitting)	100	2.0	155-1
After four baths (sitting)	96	215	150
After 12 baths (sitting)	88	180	110
			30

Our observations (therefore, are in agreement with the experimental results obtained by Branton and Tannachie that massage lowers the general blood-pressure, but they are somewhat at variance with the statement of Oliver that in arterial pressure expresses the general drift of the influence of dry massage on the circulation, unless he refers to the initial transitory rise frequently obtained. He does not state, however, whether massage of the abdomen was carried out in his experiments, presumably it was, as this is the general course adopted, in which case our observations fall into line with his, for, as has been shown, vigorous abdominal massage will abolish the fall produced by massage of the limbs and rest of the body and cause a rise in arterial pressure, where this is but lightly performed the net result is a fall. The influence of warm temperatures plus massage, as in the air douche, is to considerably augment this fall. In all probability the factor primarily and chiefly disturbed by massage is the peripheral resistance rather than the output of the heart and the result is to be attributed mainly to diminished resistance from arteriole dilatation.

EXERCISE

The effect of exercise on the blood pressure has been examined by many observers with somewhat conflicting results. "Here," as the result of his experiments found the blood-pressure to be raised during severe muscular exercise, but to be lowered after cessation of exertion. Ortel, and others found a considerable rise in blood pressure following muscular exercise. Landner Branton and Tannachie, observing the effects of resistance exercises on the circulation, using the sphygmomanometer of Mosso, found an initial rise in arterial pressure to take place soon after commencement of the exercises. During their continuance the blood-pressure fell to its original level and continued falling after cessation of movement, the fall lasting about half an hour afterwards, when it gradually rose to its initial height. They discuss the probable cause of the discrepancy between their results and those of previous observers and refer it to the different amount of exercise taken. In the case of the earlier observers the exercise taken was more severe and sufficient to increase the frequency of pulse and respiration, while in their own experiments with resisted movements the exercise was of a much gentler nature, inasmuch as the fall in pressure following the exercises to be due in great part to the dilatation which, occurs in the peripheral muscular area. The initial rise in pressure they refer in part to reflex cardiac stimulation and in part to the diminution in calibre of the peripheral muscular arteries which occurs during the shortening of the muscles which are called into play. The latter factor they consider the most potent account for the fall in pressure that occurs while the muscles are still contracting they suggest the possibility of a vasodilating substance being produced by the contraction of moderate exercises as arising from the sitting posture, walking a few steps, and again sitting down is sufficient to slightly raise the mean arterial pressure, the pulse-rate being also raised, while severe exercise in the form of a rapid run causes a considerable rise in pressure, the frequency of pulse and respiration being of course, increased. The rise thus obtained is of brief duration, the pressure falling to normal within half an hour after exercise and before the pulse-rate has fallen to its initial frequency, subsequently, however, the arterial pressure and rising of venous pressure (Experiment XVII). The observations were made on a patient suffering from chronic renal disease.

Dr. Med. Dr. J. L. 1897
Dr. L. 1893

EXPERIMENT XV—Dry Massage Heavy Movements, 10 Minutes

Pulse-rate	Arterial pressure, mm. Hg.		Venous pressure, mm. Hg.
	Maximum	Mean	
Before	83	1.5	83
After 3 minutes (rigorous massage to waist and body (abdomen excluded))	83	85	150
After 7 minutes (deep massage to abdomen)	83	160	170
			25

11st massage in the form of the air douche in which massage is administered under a warm douche conveyed by a flexible pipe playing between the hands of the massager causes an increased effect—that of temperature being added to massage. We observed here a greater fall in arterial pressure than was obtained with dry massage and consequently the abdominal massage is but highly performed.

EXPERIMENT XVI—Air Douche, Temperature 35° C

Pulse-rate	Arterial pressure, mm. Hg.		Venous pressure, mm. Hg.
	Maximum	Mean	
Before	70	150	150
After	64	150	115
			25

On the other hand, wet massage in the form of the Vichy douche in which massage is administered under a warm needle spray, the subject being in the recumbent posture, causes a rise in all pressures maximum and mean arterial, and venous (Experiment XVII). The difference between the effect of this bath and of the preceding is no doubt due to, first, the perspiration of the needle spray tending to raise the blood pressure (Experiments II and VIII), and, secondly, to the fact that the subject being in the recumbent posture abdominal massage is more efficiently performed and hence a rise in pressure results. Personal experience of the two baths bears out this difference a feeling of languor resulting after the air douche and of exhilaration after the Vichy douche.

EXPERIMENT XVII—Vichy Douche, Temperature 35° C

Pulse-rate	Arterial pressure, mm. Hg.		Venous pressure, mm. Hg.
	Maximum	Mean	
Before	64	117	83
After	66	120	55
			22

To illustrate the cumulative effect of the air douche the following example may be given, from which it will be seen that the progressive result is a considerable lowering of arterial pressure and rising of venous pressure (Experiment XVIII). The observations were made on a patient suffering from chronic renal disease.

Spinal douche—The addition of a spinal douche to the ordinary needle bath did not seem in any way to enhance its effect, a slight rise in all pressures resulting (Experiment X)

EXPERIMENT X—Needle Bath + Spinal Douche, Six Minutes, Temperature 37°, cooled at push to 24° C

	Pulse-rate	Arterial pressure, mm. Hg		Venous pressure, mm. Hg
		Maximum.	Mean.	
Before	74	165	110	22
After	70	175	117	25

Saline baths—To ascertain the effect of mineral constituents in the water the saline sulphur baths of Harrogate were first experimented with (Experiments XI and XII). Of these, the "natural" sulphur bath, consisting of the pure undiluted water raised to the required temperature by passing on its way to the bath through a heated coil, contains about 3.6 parts per mille of total solids, consisting of the chlorides and carbonates of sodium, calcium, and magnesium, the chlorides being largely in excess. Of the chlorides, that of sodium greatly preponderates. The sulphur constituent amounts to about 0.03 part per mille of sodium sulphide, with a small volume of sulphuretted hydrogen gas. The so-called "strong" sulphur bath, consisting of the pure sulphur water raised to the required temperature by admixture with hot plain water, contains about 2.1 parts per mille total solids, the sulphide amounting to 0.01 part per mille.

EXPERIMENT XI—Natural Sulphur Bath, 20 Minutes, Temperature 37° C

	Pulse-rate	Arterial pressure, mm. Hg		Venous pressure, mm. Hg
		Maximum.	Mean.	
Before	72	175	125	22
After	68	140	85	20

EXPERIMENT XII—Strong Sulphur Bath, 15 Minutes, Temperature 37° C

	Pulse-rate	Arterial pressure, mm. Hg		Venous pressure, mm. Hg
		Maximum.	Mean.	
Before	70	160	120	22
After	70	150	110	15

The result is a very marked fall in arterial pressure in the case of the natural sulphur bath, with an absolute fall, though relative rise, in venous pressure, the strong sulphur bath also gives a fall in mean pressure with a fall, both absolute and relative, in venous pressure. Comparing these with the results of hot and warm plain water baths shown in Experiments III and IV the fall in arterial pressure is seen to be much greater in the case of the saline baths at the same temperatures. This water, therefore, would seem to have the effect of enhancing the dilating power of warm temperatures on the peripheral arterioles. How far the effect is to be attributed to the salines in the water and how far to the sulphuretted hydrogen as we are unable to say.

The artificial *Naheim* baths, both still and aerated, were next examined. The still baths were made by dissolving 3.2 kilos of sodium chloride and 85 grammes of calcium chloride in 136 litres of water, giving a proportion of 23 parts per mille and 0.6 part per mille of the two salts respectively. The aerated baths were obtained the same way of Sandow's tablets which contain, in addition to the salts above, a quantity of sodium bicarbonate constant. Hence vary for the production of effervescence (Experiment XIV). The baths were given at other factors to remain the same as the plain water and

EXPERIMENT XIII—Still Naheim Bath, 20 Minutes, Temperature 34° C, 2 Kilos NaCl and 85 Grammes CaCl₂ to 136 Litres of Water

	Pulse-rate	Arterial pressure, mm. Hg		Venous pressure, mm. Hg
		Maximum.	Mean.	
Before	54	190	115	5
After	60	140	95	10
20 minutes after	60	155	110	7

EXPERIMENT XIV—Aerated Naheim Bath, 20 Minutes, at 34° C

	Pulse-rate	Arterial pressure, mm. Hg		Venous pressure, mm. Hg
		Maximum.	Mean.	
Before	53	165	125	12
After	54	140	97	15
30 minutes after	54	145	105	20

takes place, though the temperature employed is 34° C as against 37–38° C in the former experiments. The fall is greater than that which occurs with plain water and with the strong sulphur bath, though less than that obtained with the natural sulphur bath. This latter example, however, is an extreme case and represents a fall beyond that which usually occurs in this bath. On venous pressure the effect is very marked, both cases showing not merely a relative rise but an absolute increase over the original level. In the case of the still Naheim bath the subject of the example given had a high maximum arterial pressure with low venous pressure, probably due to a tightly contracted peripheral circulation which the first bath opened up to some extent. A series of baths has a cumulative effect, for in the subject in question the maximum pressure after six baths on alternate days became reduced from 190 mm Hg to 160 mm Hg before the bath, and the venous pressure was raised from 5 mm Hg to 25 mm Hg. Where the factor of effervescence is added the result is still more marked and endures for some time even after a single immersion (Experiment XIV).

Saline sulphur baths having a more potent effect than plain water baths at the same temperature, and Naheim baths yielding yet more marked results even at lower temperatures, it appears then that if the lowering of arterial pressure and the raising (either relative or absolute) of venous pressure be due mainly to lessened peripheral resistance, as is probably the case, the amount of arteriolar relaxation caused by immersion in warm water becomes progressively greater as the amount of saline material in the water is increased. Up to what point of concentration this augmentation continues we have not yet been able to determine.

MESSAGE

Lauder Brunton and Tunncliffe,* experimenting on cats and dogs, have demonstrated that massage of a considerable muscular area causes an initial rise in the general blood-pressure which is followed by a considerable fall, amounting in some instances to as much as one fifth of the original pressure. G. Oliver† in a recent series of articles on blood-pressure is "struck by the singularly small and somewhat variable effects produced by massage in the arteries and veins of normal subjects. Local massage," he says, "does not induce any obvious change in the blood pressure; the effect of general massage may be equally negative. I have, however, observed a slight rise in the arterial pressure (mean and maximum) and a doubling of venous pressure, and this observation probably expresses the general drift of the influence of general massage on the circulation in normal subjects." Our observations lead us to the conclusion that general dry massage, in the form known as *pétrissage*, while it may cause an initial rise of blood-pressure of brief duration, produces as the net result a fall in

DOUBLE PNEUMONIA IN THE SIXTH
MONTH OF PREGNANCY, MIS-
CARRIAGE, RELAPSE,
RECOVERY

BY THOMAS OLIVER, M A DURH., M D GLASG,
F R C P Lond,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

In forming a prognosis of pneumonia the circumstances of which the lung is involved, the age, habits, and physical condition of the patient, the presence of complications, and the height of the fever. A doubtless pneumonia is always a more serious affection than when part of one lung alone is involved. Pneumonia is in most instances a localized expression of one of a constitutional disease or owing a microbe for its cause, and death comes from cardio failure or to peripneumonia. When inflammation of the lungs occurs in a woman far advanced in pregnancy, when her blood is so altered physiologically as to be pathological, the distended abdomen by preventing easy descent of the diaphragm creates a fresh mechanical obstacle to the breathing, thereby endangering

On Feb 13th I was asked to see in consultation with Dr Taylor of Chester Le Street an apparently healthy and well-developed woman aged 28 years. She was lying in bed with her shoulders elevated, her face flushed, and she was breathing with difficulty. There was no question as to her previous health or temperate habits. She was the mother of two children and was near the end of the sixth month of pregnancy. Six days before I saw her—i.e., on Feb 7th—she had gone to a concert after leaving the hall. There was, however, no report of any other cause for the complaint.

On the 10th of June, 1861, I was informed by a friend that a young man, who had been a member of the church, had been killed by a mob. I was very much distressed at the news, and I immediately went to the place where he was killed. I found the body of the young man lying on the ground, and I was very much distressed at the sight. I immediately went to the place where he was killed, and I found the body of the young man lying on the ground, and I was very much distressed at the sight. I immediately went to the place where he was killed, and I found the body of the young man lying on the ground, and I was very much distressed at the sight.

1. The first of these is the fact that the
 2. Government has failed to provide a
 3. clear and consistent policy on the
 4. issue of the environment. This has
 5. led to a lack of confidence in the
 6. Government's ability to manage the
 7. environment effectively. This is
 8. a major problem for the country
 9. and it is one that must be
 10. addressed as a matter of
 11. priority. The Government must
 12. develop a clear and consistent
 13. policy on the environment and
 14. ensure that it is implemented
 15. effectively. This is the only way
 16. to ensure that the environment
 17. is protected and that the
 18. country is able to sustain its
 19. economic growth in a sustainable
 20. manner.

[illegible]

was ordered to procure sleep if possible. The most important question which Dr. Taylor and I had before us for consideration was whether we should or should not induce paraly-

If it would appear, then, that these observations support the conclusions of Brunton and Tunncliffe that the effect of exercise on the blood pressure will depend on the nature and severity of the work performed. The first effect or all forms is to raise the arterial pressures to an extent roughly proportional to the amount of exertion, probably because increased output of the heart tending to raise the pressure is in excess of peripheral dilatation tending to lower it, the arteries being as yet unrelaxed. If continued exercise be such as to markedly increase the frequency of the heart beat a rise in pressure results which is maintained throughout the exercise if that be severe, the factors tending to raise the pressure (whether increased output, diminishing oxidation, or others) more than compensate for the widening of the periphery. On the other hand, if the exercise be less severe and the pulse rate be not disturbed, arterial relaxation takes place while the output apparently may remain the same or at least be not greatly increased, so that a fall in pressure occurs. In all cases degrees of peripheral dilatation After exercise of all kinds the arterial pressure falls below its original height, the venous pressure remaining raised, and the starting point of both is regained in from 20 minutes to an hour afterwards.

The result obtained may vary to some extent with the condition of the subject experimented upon as to being accustomed or not to exercise inasmuch as moderate exercise may be to him relatively severe. Temperatures also appear to be a factor of moment in determining the result, for the fall in pressure after moderate exercise is greater on a warm day and the subsequent return to normal occupies a longer period than in cold weather.

Symptoms.—1 Cold baths raise the arterial pressures, most minimum and mean, and lower the venous pressure, after reaction the arterial pressure falls and the venous pressure rises. 2 Percussion added to cold increases the rise in arterial pressure and both absolutely and relatively lower the venous pressure. 4 Turbidity baths lower the arterial and venous pressures to a greater extent though the fall in venous pressure is proportionately not so great as that in arterial pressure. 5 Baine baths at warm temperatures lower the arterial pressures very greatly, less than plain water baths at the same temperatures, the venous pressure, though absolutely lowered, is relatively raised, whereas the non-anomalous material in solution is considerable whether the temperature of arterial pressure takes place while the venous pressure becomes absolutely raised. 6 Dry massage lowers the arterial pressures and relatively or absolutely raises them, provided the abdomen be not raised in all press situations occurs. 7 Warm temperature *plus* massage, as in the Turkish bath, has a more powerful effect in the same direction. The effect of a series of at 8 The effect of exercise on the severity of exertion. In all good pressure depends upon the severity of exertion. In all poor pressure depends upon the severity of exertion on the temperature of the exercise and the temperature of the atmosphere.

the pressure falls below its original level. Oliver¹⁰ agrees with the general conclusion that exercise raises the mean arterial pressure, but he finds that this result is by no means invariable, the mean pressure, according to him, remaining stationary or even falling in some subjects after exercise. He considers the invariable result of exercise, moderate or severe, to be a rise in maximum pressure, which, he says, is due to increased energy of contraction of the ventricle. Whether the mean pressure becomes lowered or raised depends, he maintains, on the relation between the amount of arteriolar relaxation at the one end and the force of the ventricular pump at the other, the former being excessive without undue increase in the latter a fall in mean pressure results, and *vice versa* a rise. He further states that it is in subjects with a high mean pressure and relatively low venous pressure—that is, in subjects in whom peripheral resistance is high—that a fall in mean pressure is likely to follow exercise, and that when it does a marked rise in venous pressure occurs.

In the endeavour to throw further light on the subject we examined the effects of exercise of various grades of severity from gentle resisted movements upwards through dumb-bell exercises requiring a gradually increasing amount of exertion to the strenuous labour of cycling rapidly uphill, with results which are tabulated below. After corroborating the observation of Hill that the mere rising from the sitting posture and walking a few steps raises slightly the mean pressure we found that if the blood pressure be taken in any position with the muscular system relaxed, the rendering of the skeletal muscles throughout the body tightly rigid without holding the breath has the effect of at once raising the pressures—maximum, mean, and venous—to a considerable extent, the pulse frequency being also raised (See Exercise I). A transient fall in venous pressure may sometimes be noted immediately the muscles contract, probably from constriction of peripheral muscular arteries by contracting muscle fibre, the fall, however, rapidly gives way to a rise. These changes may be explained as partly the result of increased output of the heart, as indicated by the moderate increase in the rate of beat, and partly the result of diminished capacity of the vessels, and the influence of an increased amount of carbonic acid in the blood must not be overlooked.

With resistance movements performed gently without causing a rise in the pulse rate we obtained results corroborative of those of Brunton and Tunncliffe—viz., an initial rise (or delayed fall, as in the example given) in mean and maximum arterial pressure, followed by a fall during continuance of movement, with a further fall subsequently and a gradual rise to normal, the venous pressure rising as the arterial pressure falls (Exercise II). Where, however, the resistance was made stronger and the exercise became such as to increase the frequency of pulse and respiration a rise in maximum pressure resulted, with a fall in mean pressure and a trebling of venous pressure (Exercise III). If the difference between the mean and maximum pressures, compared with the mean pressure as taken by the instrument, be any guide to the amount of force with which the blood is discharged it would appear that this must be here increased, and inasmuch as the mean arterial pressure is lowered the amount of peripheral dilatation must be such as to more than counterbalance the effect of increased output, which would tend to raise the mean pressure if other factors remained constant.

Dumb-bell exercises were next taken, those advocated by Sandow¹¹ being chosen as putting into action successively the main groups of muscles in the body. When slowly and deliberately performed, to avoid quickening either pulse or respiration, an initial rise in all pressures occurred with a subsequent fall during the exercise in arterial pressures and a further rise in venous pressure, the return to normal being complete in 20 minutes after cessation of exercise (Exercise IV). This result is practically identical with that given by gentle resisted movements. The same exercises performed more rapidly and vigorously gave as the net result a lowering of mean pressure with slight rise in maximum pressure and a doubling of venous pressure, the exercise apparently increasing the output of the heart without disturbing the rate of working (Exercise V). When performed more rapidly still and with great vigour in order to quicken the pulse the initial rise in arterial pressure became more marked, increased as the exercise

continued, and was sustained to the end, the venous pressure showing a marked rise. Afterwards, however, the mean pressure fell to below normal, while the maximum and venous pressures also fell slightly but still remained well above normal. The effect was of brief duration, for 25 minutes after discontinuing exercise the arterial pressures regained their original level, the venous pressure remaining slightly raised (Exercise VI). The violent exertion of cycling rapidly uphill against a strong wind caused a rise in maximum pressure with a rise to a less extent in the mean pressure and a large rise in venous pressure, respiration and pulse rate being greatly accelerated. The arterial pressures fell after exercise to below normal, while the venous pressure rose higher, as occurred in the preceding case, of which this is merely an exaggeration. The length of time that elapsed before the starting point of pressure was regained was greater after the more severe exercise (Exercise VII). In these two instances the marked rise in venous pressure would seem to indicate a considerable degree of peripheral dilatation. In endeavouring to account for the rise in arterial pressure the effect of increased CO₂ must again be considered. Possibly the rise may be attributed partly to this cause and partly to increased output of the heart, notwithstanding Stewart's statement that where the pulse rate is greatly increased the output per heart beat is diminished and the output per second may or may not alter but is usually also diminished.

¹¹ Strength and How to Obtain It, by R. Sandow. London, 1897.

prepared for the event, and besides there was just the chance that the problem would be solved by miscarriage. We decided not to terminate the pregnancy.

The after course of the illness is extremely interesting. Two or three hours after I left her she was seized with labour pains. These came on at 10.45 P.M., and before 11.5 P.M., when Dr Taylor reached her, the child was born. There is some doubt as to the whether the child was born alive, but it was dead on Dr Taylor's arrival. There was no trouble with the placenta and the lochia, though scanty, remained healthy throughout. The interesting and fortunate circumstance in regard to the confinement is that while we rather dreaded a miscarriage on account of the compulsory holding of the breath which expulsion pains naturally cause the labour was completed in less than 20 minutes, and it seemed as if the act of parturition disturbed the patient very little. No necropsy was made upon the infant. Once the mother's temperature began to fall to 100° she was overcome by sleep, at times so profound as to overpower her even when engaged in ordinary conversation. It was a deeper somnolence than ordinarily occurs after pneumonia. By Feb. 26th the patient was well again. She had been up for a few days, her pulse and temperature having been normal, but on this date she was again seized with pain in the right chest and on the following day there was distinct dulness with tubular breathing over the upper part of the left mid lung posteriorly, her pulse rose to 120 and her temperature rose to 102°. The expectoration which had been absent for several days again returned and it was observed to be rusty once more. On the third day after the relapse the pulse fell to 100, the temperature declined to 100.5°, the respirations to 24, and the patient expressed herself as feeling comfortable and free from any pulmonary embarrassment. It was not until March 5th, however, that the lung showed signs of clearing up and the temperature stood at 99° morning and evening. The urine never contained albumin. The first attack of pneumonia lasted 11 days, but the second was of only seven days' duration and was unaccompanied by the extreme prostration and the hurried and anxious breathing noticeable in the original illness. That it was a veritable relapse was shown by a bacteriological examination of the sputum. Some of the expectoration of March 4th was sent to Dr Harcastle, demonstrator of bacteriology in the Durham University College of Medicine, and he reported (1) as the result of staining that the sputum contained pneumococci, and (2) that in an agar agar cultivation the colonies appeared like drops of dew on the agar which when examined microscopically proved to be diplococci. That the micro-organisms were pneumococci is beyond dispute.

When pneumonia attacks a pregnant woman there is naturally a risk to both the mother and the child. Miscarriage takes place in a very large percentage of these cases. The death rate, too, is high. In Hirst's "American System of Obstetrics" mention is made of 43 cases of pneumonia occurring during pregnancy. In 21 of these there was premature expulsion of the foetus. 28 of the 43 patients had not passed the sixth month of pregnancy, and of these 11 aborted, while of the remaining 15 who had exceeded this period the pregnancy terminated prematurely in 10. From these statistics it would appear as if the tendency to abortion increased with the advance of pregnancy. Of the 15 women seized with pneumonia after the sixth month of pregnancy seven died. It was Tarnier's opinion that "the more advanced the pregnancy the greater the probability of an expulsion of the foetus and the graver the prognosis for mother and child."

My own experience leads me to express the opinion that so far as treatment is concerned it is better not to attempt to end the pregnancy. It was only too apparent in our patient that if the uterus could have been rapidly emptied there would have been a gain of air space to the mother, but those of us who have had to empty a pregnant uterus short of the full term know the difficulties of the process and are aware of the risks to which maternal and foetal life are exposed. Nature will neither be taken unawares nor will she be hurried beyond limits at this particular period. The induction of premature labour, however rapid, is always tedious and a woman may die during the operation. The muscular pains and the sudden expulsion of the foetus act too frequently like surgical shock to the mother. Add to these pneumonia and what can be the effect of strong expulsive pains with suspended respiration but for more blood to be

thrown into already damaged lungs and an extra strain imposed upon the heart? In the treatment of disease we rely upon experience. What, then, is the verdict of experience in regard to the induction of premature labour when severe pneumonia complicates pregnancy? Statistics certainly do not favour obstetrical interference. Of 18 women who were the subjects of pneumonia and in whom the pregnancy was interrupted Matton¹ informs us that nine died, while of 20 women suffering from pneumonia but whose pregnancy was not interfered with only one died. As regards the children born under these circumstances it may be said that most of them are born dead or die very shortly after birth and when a necropsy has been made the lungs have been found affected and the internal organs congested.

Pneumonia itself tends to terminate a pregnancy. Nearly one half of the women who are affected abort. In all these cases fever is an important element, it increases the danger by quickening the respiration and causing cardiac failure. Pneumonia interrupts pregnancy in about one third of all cases before the sixth month and in two thirds between the sixth and ninth months. The maternal mortality may reach 50 per cent, while that of the foetus rises higher, being probably nearer 80 than 50 per cent. It is needless to add that when labour occurs in pregnancy complicated by pneumonia it is the duty of the practitioner if the parts are at all dilatable and the head presenting to shorten the process as far as possible by the gentle use of the forceps, keeping an eye on the patient afterwards for cyanosis. Should this develop he should not be in too great a hurry to check any reasonable amount of bleeding that may be present.

Newcastle-on-Tyne

A CASE OF ULCERATIVE ENDOCARDITIS TREATED WITH ANTI-STREPTOCOCCIC SERUM

By BERTRAM M. H. ROGERS, B.A., M.D., B.Ch. Oxon,
PHYSICIAN AND PATHOLOGIST TO THE ROYAL HOSPITAL FOR SICK
CHILDREN AND WOMEN, BRISTOL.

ANTI-STREPTOCOCCIC serum is still on its trial and the following case may be recorded without prejudice and help to define its value as a remedial agent. I say "without prejudice," as a single case, though it may be as complete as the one now described, is of little value, but taken in conjunction with the others already reported and possibly with others still to appear it will be useful. Though recoveries have been recorded the disease is almost universally fatal, so that any serum or other agent which would counteract the toxin would be most acceptable. The chief difficulty lies in the fact that we have to deal with a disease in which the infection may be caused by several distinct micro-organisms, or a group of organisms, while the symptoms appear the same in every case. It is only by a cultivation from the blood in each case that the cause can definitely be ascertained and as yet we have a serum to counteract the toxin of streptococci only, and it is even doubtful whether it will cure every case of streptococcal infection. The present case was so typical clinically of ulcerative endocarditis that it need only be reported in brief.

A boy, aged 10 years, was admitted into the Royal Hospital for Sick Women and Children, Bristol, in October, 1898, with acute rheumatism of the big joints. There was a soft systolic murmur at the apex of the heart. Under treatment the swelling of the joints disappeared, but the temperature continued between 100° and 103° F. The patient then developed pleurisy in the left axillary region and some bronchitis. These in their turn got better, but the spleen became enlarged and tender. The temperature continued high and a double murmur developed at the base of the heart, and a trace of albumin appeared in the urine. Diagnosing the condition to be one of ulcerative endocarditis of the aortic valves I asked Dr J. O. Symes, the bacteriologist to the infirmary, to examine the blood bacteriologically. He reported as follows, the blood being examined on Nov. 28th, 1898: "Two cubic centimetres of blood were taken from the arm in the following manner. A tape was tied tightly round the upper arm midway between

known seem to bear a new importance in support of the present thesis. 1 The deeper of the two layers of the superficial abdominal fascia contains much yellow elastic tissue capable of development.¹ It forms one of the strongest of the various portions of the abdominal wall and is more or less intimately connected with the external oblique muscle and its fascia. 2 The intercolumnar fibres which extend partially across the superficial abdominal opening in the aponeurosis of the external oblique muscle are "slender" and send a "thin membrane" downwards upon the spermatic cord.² The "internal pillar" which goes to form Gimbernat's ligament sends a reflection of fibres upwards and inwards which reach the middle line and become incorporated with the sheath of the rectus muscle. 3 The aponeurosis of the internal oblique is inseparably united with the aponeurosis of the external oblique and that of the transversalis. 4 The transversalis fascia is, thanks presumably to nature's provision, strongest in the lower part of the abdomen and encloses, as it were, the femoral vessels as they pass under Poupart's ligament. From the margins of the opening of the internal abdominal ring the "delicate" infundibuliform fascia is prolonged upon the cord or the round ligament.³ I contend that each and all of these structures, which are of vital importance in the production of all hernias, are capable, by suitable measures, of great increase in vascularity in muscular and aponeurotic substance, and therefore in thickness and resistance to the extrusion of any viscous.

Although not a few surgeons operate upon hernia in infants of two and three years of age and under, it may, I think, be considered the more general practice to recommend the prolonged use of a well made truss. Every practitioner has many cases in his mind's eye in which this treatment has been successful as a "radical"—i.e., complete—cure, and adult life is reached without any signs of the old hernia. As Mr Eccles remarks in his paper on the Treatment of Inguinal Hernia in Children,⁴ "permanent closure of the processus vaginalis will be obtained in the majority of cases only after a continuous action of the pressure of a spring truss over a period of some years. A cure, therefore, can be safely predicted, but the truss should not be discarded until the child has reached the age of at least three years." Such a result can only be explained by the development of the child and a gradual process of more or less complete closure of the hernial sac.

In adults, however, the case is different and if the verdict of the surgeon be cast for treatment by bandage it is rare that an expectation of "cure" is held out, the patient being rather bidden to choose between the alternatives of operation with cure or a truss for the rest of his life with constant exposure to descent of the hernia, irreducibility, and even strangulation—the truss, that is to say, is regarded merely as a palliative measure.

Now, the operative treatment of a small hernia in a young adult is not to be entered upon lightly. It is a plastic operation and yet a major one. An untoward result, though rare, is yet one of the most terrible "calamities of surgery." Nor is the profession decided as to the best method of operating, almost every eminent surgeon having given his name to one or other procedure. "Plurima: leges corruptis summa respublica," remarks Tacitus, and it may safely be said that as no one method has generally superseded all others so we are still looking out for an infallible operation, operative treatment remaining in many cases an ultimate necessity. Taking as a type the ordinary small reducible inguinal hernia my treatment is as follows. 1 Keep the hernia within the abdomen continuously and permanently by means of a well applied truss which may be changed for another of stronger pressure, of greater mobility, of different material, &c., as circumstances may demand. 2 Systematically develop by suitable exercises to the greatest extent possible the muscular and aponeurotic structures of the abdominal wall.⁵ A few words upon each of these two points.

1 *The truss*—The hernia once recognised, and the truss properly applied, must not be allowed to descend. One such complete descent may annul the results of weeks of treatment. A special truss should be used when the patient is in the bath and, if necessary, even when in bed in the

horizontal position. On no account must the bowel enter even the internal inguinal aperture. As to the truss the French and English forms differ considerably and on the whole I think the former is to be preferred on account of its greater simplicity and lightness. During some of the exercises prescribed the truss may be dispensed with altogether as the patient is on the horizontal plane with the pelvis possibly a little raised, or a lighter, more mobile truss which permits greater freedom of movement may be used. Such are well made by Rainal Brothers, Paris.

2 *The muscular development*—I do not think that it will be denied that when a truss is worn the advice is usually given to the wearer to avoid all muscular effort. The consequence is that a more or less sedative life is led, the abdominal parietes atrophy muscularly rather than gain strength, or adipose tissue is formed, and the inguinal canal becomes less and less resistant to the extrusion of the hernia. On the contrary, I advocate the practice of all such muscular effort as will not tend to force the hernia into its sac and if the truss be an adequate one there are few reasonable exercises that need be forbidden. Those who have examined some of our public school or university athletes must have been struck with the extraordinary part taken in their general muscular development by the abdominal muscles. When contracted the tendinous intersections of the recti are well-marked hollows and the mass of the obliques at each side is not only easily distinguishable but becomes actually prominent. Gymnasts and "strong men" show this to an even greater extent and if the inguinal canal of such subjects be examined it is surprising to find how small and how firm the internal ring is and how much slighter the impulse upon coughing is than can be elicited in the more normal individual.

I have followed a number of cases now in which a great increase of development has been obtained in three months, six months, or a year by patient and suitable training. The means used may be simple movements as indicated in the Swedish system, better still by resisted movements by means of one or other of the "exercisers" now in such popular and varied use. It is probable that the abdominal muscles contract more or less together and that isolated action of one or other is exceptional. In sitting up, for instance, the obliques aid the recti muscles, but in rotation with flexure of the pelvis the share of the recti muscles must be insignificant. The action of these muscles varies according as the vertebral column, the pelvis, or the thorax are fixed. They are also thrown into a state of contraction when any violent muscular effort is made, thus bracing the parietes of the abdomen and supporting its contents. They come into use in forcible expiration and in efforts of expulsion from the thoracic and abdominal cavities.

The common sense therefore, both of the surgeon and of his patient will suggest the simple exercises necessary or expedient. Among the best are the following. 1 The patient, with his hands at his side, raises himself from the dorsal decubitus to a sitting posture 20 or 30 times twice or oftener a day. 2 Similarly, from the horizontal position, let both legs be raised from the ground almost to the perpendicular. This also 20 or 30 times tall there is distinct fatigue. 3 Modify the first of these three exercises by raising the body sideways in a rotatory movement and thus exercise the obliques. Similar modifications may be introduced by extending the arms during the movements, by the use of dumb-bells or exercisers, and so on.

Paris

COMPLIMENTARY DINNER.—On May 26th Mr Robert Stirling, M.B., C.M. Glasg., of New Cumnock, Ayrshire, on his leaving the burgh, where he had been in practice between eight and nine years, was entertained to dinner at the Afton Hotel by his friends in testimony of their high regard for him.

LLANELLY HOSPITAL.—The annual report of the Llanelly Hospital for 1898, which has just been issued, states that at the end of 1897 the institution had an unfavourable balance of £1000, but that at present there was a balance in hand of £192. The committee had found it necessary to reduce the number of beds, but doubtless this number would now be increased. The average weekly cost per patient was 9s. 2½d. for maintenance and 13s. 6d. for administration. Mr Stadt had offered to guarantee a sum of £500 for the next two years conditionally upon the working men doubling their subscriptions.

² Loc. cit., p. 329. ³ Loc. cit., p. 336.

⁴ Brit. Med. Jour. May 13th, 1893, p. 1148.

⁵ This last principle is gradually being recognised in France—usually the last country to appreciate the value of physical exercises—and Lucas-Championnière considers the bicycle to be the ideal form of exercise for the subject of hernia both when wearing a truss and after having been operated upon.

NOTE ON A CASE OF HERNIA OF THE VERMIFORM
APPENDIX INTO AN OLD FEMORAL SAC

BY THOMAS F CHAVASSE M O Edin, F R C S Edin,
L Eng,
SENIOR SURGEON TO THE BIRMINGHAM GENERAL HOSPITAL.

The case here recorded resembles in many particulars those recently described by Mr Edmund Owen and Mr

IV H Battle

On May 8th, 1869, I saw in conversation with Mr. Albert Jackson of Smethwic, Birmingham, a patient, aged 65 years a widow, and the mother of 10 children, who for some

years had suffered from a small hernia for which a suitable belt and pad were worn with advantage. She was

also afflicted with rheumatoid arthritis of the hip joint and she had noticed for some years that from time to time a

substance made its appearance in the position of a femoral hernia, on the right side which was most marked if any straining took place during the acts of micturition and

defecation. During the first week in May she became aware that the lump was persistent, that it was larger than ever

before, and also that it was hard, she therefore consulted Mr Jackson, who sent her to bed and applied heat. As no

appreciable change took place a consultation was held. On examination a fixed tumour was found to exist at the base of Scarp's triangle about three inches long and one and a half inches wide.

of leopards' stripes; above each eye a
Roupar's ligament and tailing off towards the pube

There was no deep-seated function in the mind of the uneducated

Կրթության հարցերի վերաբերյալ Կոմիտեի անդամները համաձայնեցին, որ հարկ է դնել համապատասխան օրենսդրություն, որով կարգավորվի համապատասխան կրթության հարցերը:

exploratory operation an expected line of treatment was adopted and under the influence of rest and heat the tumor

gradually lessened in size. On May 19th a second consultation was held. The tumor was then of about the size of a

Lagerbomme orange, soft and succulent, but containing in its deeper parts a hard mass which felt like the unsoftened portion of a lampshade stand. On one side of the

On the following day (May 20th), with the assistance of Mr. Arthur Jackson

and Mr. Willard Jackson, I made a longitudinal incision into the tumour which gave exit to about six drachms of a dark-

coloured brown and revealed an old femoral sac one-eighth of an inch containing a much congested and inflamed appendix three inches in length and of 1/4 inch diameter.

At first sight this looked like a knuckle of smelt, but on closer inspection it was found to be a piece of wood.

Its mesocolon lay to the outer side and a small mass of adherent omentum lay to the inner side. The appendix was

removed in the ordinary manner and in removed stump was pushed into the peritoneal cavity. The omentum adherent to the inner side of the sac was cut and the stump was pushed into the peritoneal cavity. The omentum

14-00000

closed by sutures after the insertion of an iodoform gauze drain. No unfavourable symptoms followed the operation.

This case apparently bears out the contention of Mr. Meadum Eccles that the inflammation of the appendix in these instances often takes place after its removal.

hernial sac and that the strangulation is secondary, being caused by the acute inflammatory processes taking place in the

conjoined space. In this patient the crural ring was apparently of about the normal size and the stump of the appendix readily slipped back into the abdominal cavity.

the neck was not nipped. Judging by the thickness of the sac and the adhesions of the omentum the hernia had probably

been in existence for a long period in an irreducible form. Mr Jackson states that three weeks before he was first contacted the

relative, accidentally received a blow in the region of the

¹ THE LANCET May 6th, 1899 pp. 1222, 1223

correct and this possibly may have been a contributing factor to the protests of the appendix. When removed this organ especially at a first removal, was very edematous and if it had been allowed to remain might eventually have become gangrenous from the effects of the inflammatory exudations it contained on coarction or other foreign body. As in the cases of Mr Edmund Owen and Mr W. H. Battle this patient was a married woman advanced in years and my experience is quite in agreement with that of the former surgeon as to the rarity of this condition, this being the first case which I have ever met with either in my hospital practice or in my private practice Birmingham

NOTES ON A CASE OF ADDISON'S DISEASE
TREATED WITH SUPRENAL
EXTRACT
BY ARTHUR FOSTER, M D, O M EDIN

IN October, 1898, I was consulted by a robust woman, aged 38 years, a weaver by trade, for symptoms of well-marked Addison's disease. She had had three normal labours, the last at 23 years of age. Menstruation began at 14 and ceased with the first pregnancy. The following

and again became confined to bed. However, in December she recovered and though she had lost flesh she averaged 66, and she was able to sit up for several hours within a month the pain in the back had disappeared, the pulse normal gland subsided, taking four a day at the end of a week and was at once given the regular ration of 100 mgm. of vitamin D₂ and 100 mgm. of vitamin E.

[illegible]

March 15th, when cardiovascular arrest occurred and becoming comatose. She died 24 hours later. No post-mortem examination was obtainable.

effect of suprarenal gland treatment. The patient certainly

got some relief from it. The pain in the back disappeared and the pulse was quickened. She always expressed herself as feeling better after taking the tabloids, she said that she felt more faint when she missed a day. She took them up to a fortnight before her death. The pigmentation did not appear to be influenced in any way by them.

Blackburn.

NOTES ON A CASE OF "LUPUS LYMPHATICUS" OF THE EYEBALL

BY DAVID WALSH, M.D. EDIN,
PHYSICIAN TO THE WESTERN SKIN HOSPITAL, LONDON
AND

SYDNEY STEPHENSON, M.B., F.R.O.S. EDIN,
OPHTHALMIC SURGEON TO THE KYELINA HOSPITAL AND THE NORTH
EASTERN HOSPITAL FOR CHILDREN

THE following case is one of such rarity as perhaps to warrant a short account in the pages of THE LANCET. So far as we can ascertain few similar cases have hitherto been recorded in this country. Fortunately there can be no doubt as to the diagnosis, for the patient was shown at the Dermatological Society of Great Britain and Ireland on June 29th, 1898. The diagnosis was there confirmed by the President (Dr Radcliffe Crocker) and other members present. Dr Crocker agreed that the case came within the same category as those called by Mr Hutchinson "lupus lymphaticus" but which he himself called "lymphangiectodes" or "lymphangioma circumscriptum." The case is briefly as follows.

A single woman, aged 18 years, who was seen by both of us in May, 1898, complained of a disfiguring condition of the right eyeball and lids which had existed since infancy but which had not got worse. The patient's general health was good and she was well nourished. No family history was available. As regards the right eye, externally there was apparent lengthening of the eyebrow, and the eyeball was prominent. The palpebral fissure measured 38 millimetres, as against 28 millimetres in the left eye. The lids were swollen and thickened but could be distinctly pitted on moderately firm pressure. The interpalpebral space was twice as broad as was that of the other eye. The cornea was small, the globe was of less size than was that of the sound eye, and there was an external strabismus of 25°. The ocular conjunctiva showed a nævoid and vesicular condition as we have described later in detail in this note. The vision of the left eye equalled $\frac{6}{6}$ (Jaeger). With the right eye the patient could make out the number of fingers held up against a strong light at a distance of one metre. The disc of the right eye was ill defined, the retinal vessels were large and rather tortuous. Both eyes showed dotted opacities in the lens, less marked in the left eye. Several strands of persistent pupillary membrane were present in the right eye, which presented an external nævoid condition. There were an enlarged caruncle and an enlarged semilunar fold which had a pale cædematous look. The fold was merged above and below in thickened conjunctiva and externally it was continuous with a translucent and vascular growth on the ocular conjunctiva. This growth consisted of a number of jelly like elevations, arranged roughly in the shape of a ring round the cornea, leaving a clear space of about one eighth of an inch at the corneal margin except at its upper segment where the growth impinged on the cornea. These yellowish translucent elevations had numerous punctate hæmorrhagic injections and fine blood vessels. In places the jelly like bodies were about one eighth of an inch in thickness and were pouch like. The patient stated that the eyes had got black at times and that there used to be a lump and got black at times and of the orbit. The capillaries sometimes at the inner angle of the eye.

The chief interest of this condition lies in its exact resemblance to Mr Jonathan Hutchinson's "lupus lymphaticus." The jelly like pouches on the eyeball were clearly lymphatics. It seems possible from the history and from the dilated surface capillaries and congested retinal vessels that the eyelids and orbital contents generally may be affected with a mixed vascular and lymphatic nævus. In that case it is interesting to note the differing appearances of what we must assume to be a common underlying pathological condition. The elephantiasis of the eyelid and the nævus lymphaticus

of the eyeball, if this view of common origin be accepted, are possibly two distinct expressions of some congenital local affection of angio lymphatic type. The present lesion is congenital, non infective, chronic, and associated with congenital nævoid manifestations. Mr Hutchinson figures a patch at the back of the tongue in a young girl and remarks that the aspect of the mucous membrane exactly resembles that of the skin. The present case does not exactly tally with Mr Hutchinson's lupus lymphaticus inasmuch as it is apparently non infective and is not associated with attacks of erysipelatous swelling.

OF

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI De Sed. et Caus. Morb., lib. iv. Proœmium.

LONDON HOSPITAL

A CASE OF ADDISON'S DISEASE IN WHICH THE BLOOD-PRESSURE WAS TAKEN TWO DAYS BEFORE DEATH

(Under the care of Dr CHARLEYWOOD TURNER.)

THE great value of Hill and Barnard's sphygmometer is that by its use a numerical value can be given to the arterial tension in any case, and it is thus much easier to compare the tension with that in other cases or with the tension in the same case at another time. The great reduction from 120 to 73 mm. of mercury is very striking. As to the value of suprarenal feeding in Addison's disease a certain number of patients receive much benefit, others for a time improve, while in most of the cases hardly any improvement follows. Sydney Ringer and A. G. Phear have collected the cases in which this treatment was followed. For the notes of the case we are indebted to Mr Reginald Wilson and Mr Harold L. Barnard.

A man, aged 53 years, was admitted to the London Hospital complaining of extreme weakness without wasting. For two years he had been suffering from progressive loss of strength, but he had kept at his work until a fortnight before admission, when he was compelled to give in and take to his bed. In addition to the extreme debility and the irresistible desire to lie down he complained of frontal headache and vertigo associated with nausea and vomiting on several occasions and loss of appetite. His head would swim at times so that he had to grasp some support to prevent his falling and he always felt drowsy although he did not sleep well at night. He was quite clear that he had not lost flesh at all nor had he suffered from actual syncope. For three weeks he had been constipated and had a burning pain about the anus upon defecation the result of a fissure of recent origin. He had also had difficulty in micturition for the last few months and had to get up four or five times each night to micturate, the quantity of urine was subnormal, the specific gravity being low. There was no urethral trouble.

As he lay in bed the patient seemed to be in fair condition, his eyes were bright and his face was not wasted. There was no anemia of the mucous membranes. His muscles were well developed and fairly firm, but very feeble in their action. His grip was weak. His skin was perhaps a little brown and this was rather more marked over his left elbow, but there was no excessive pigmentation at points of pressure. On examining his mouth, however, small spots of brownish pigment were seen all over the palate and the mucous membrane of the cheeks was affected with an almost black staining, while that of the lips was of a bluish black colour. The area of cardiac dulness was diminished and the heart's impulse was scarcely perceptible, whilst the heart

Medical Societies.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY—An ordinary meeting of this society was held at 20, Hanover square, W., on June 1st, the President, Dr R Fortescue Fox (Strathpeffer Spa), being in the chair—Mr H Shirley Jones read a paper on the Treatment of Neuritis and Neuralgia by the Droitwich Brine Baths. He said he considered obstinate neuralgia and neuritis for the most part associated with, and dependent upon, a debilitated condition and believed gouty neuralgia to be more the result of weakness than the effect of any uric acid on the nerve itself. The nerve most affected was the sciatic for obvious reasons, for it was the most difficult nerve to rest and the large surface over which it extended rendered it more prone to injury from cold, &c. Next in frequency was, perhaps, the fifth. Obstinate cases of neuralgia were met with accompanying malignant diseases. He had seen also three cases of sciatica following the apparently successful removal of mammary carcinoma which would only admit of very temporary relief, each patient died within two years of onset without any material benefit or any evidence of return of malignant disease. He related three cases of intense neuritis leading to insanity—Dr Douglas Kerr (Bath) said he could testify to the benefit which he had known in severe cases of neuralgia from the Droitwich bath treatment. He asked Mr Shirley Jones for particulars of treatment—The President remarked that neuralgia in its various forms was usually relieved under balneological treatment. It acted doubtless as an eliminant and also tended to remove the sub-inflammatory conditions on which most cases of neuralgia depended. He also called attention to the use of cold douches for neuralgia by the French—Mr Bowen Davies (Llandrindod Wells) asked for further particulars of the methods of treatment at Droitwich—Mr Shirley Jones, in reply, said that he had chosen that subject as being of interest because he thought that more brilliant results were obtained from these waters in cases of neuralgia and neuritis than in any other disease. The cases of neuritis which he had mentioned showed a peculiar obstinacy and each led to a very unusual complication—viz, insanity. The treatment he adopted at Droitwich in neuralgia and neuritis consisted for the most part for acute cases in the use of a hot reclining bath without massage or electricity but with as complete rest as possible, in cases of the lower limb rest in the recumbent position, for the upper limb rest in a sling, and in uncomplicated cases no drugs at all. For the relief of pain he used hot brine as a compress. As the acute stages passed off the douche over the course of the nerve came into use, the temperature and the length of time varied considerably with the amount of pain and the idiosyncrasies of the patient, the temperature of the douche being from 115° to 80° F usually, and he had occasionally found great benefit from a temperature as low as 65° given as a douche, particularly in cases where there had been atrophy of muscles resulting from a neuritis, there, too, he found great benefit from the use of the swimming bath, where, owing to the great buoyancy of the water, exercise of any limb might be effected with a minimum of exertion, and thus he thought a very important point in the development of atrophied muscles, apart from that the swimming bath had a very decided tonic effect and as such was very useful in the treatment of chronic neuralgia—A paper written by Dr Ivor Murray was then read on Scarborough as a Health Resort in Phthisis.

ISLINGTON MEDICAL SOCIETY—A meeting of this society was held at 25, Highbury place on May 16th—Mr Arbuthnot Lane read a paper on the Pathology and Treatment of Adenoids. He pointed out that the term "adenoids" was applied to an enlargement of the lymphatic tissue described in anatomical works as the pharyngeal tonsil and that from its proximity to the posterior nares and Eustachian tubes it readily interfered with their functions, and the operation for its removal was advised with the object of these apertures. Years had now elapsed since he had seen that the hypertrophy of the pharyngeal tonsil and inflammation of a lymphatic tissue consequent upon an area the lymphatics of which drain into the removal of the secondary infection and not with the primary source

of trouble. He also recognised that the naso-pharyngeal sequence was but an accidental consequence of a general condition which occurred in children possessed of little vitality resulting from an imperfect respiratory capacity in the first instance. On this ground he attacked the primary infection of the naso-pharynx, expecting that its disappearance would in time be followed by a return to their normal condition of the pharyngeal, faucial, and cervical lymphatic glands, as well as by a normal development of the naso-pharynx, which was always imperfectly developed in chronic cases because the forced draught of respired air through the cavity had been in abeyance. He effected this by improving the vital capacity by regular respiratory exercises, all inspired and expired air being driven through the nasal cavities, the mouth being kept closed. This treatment met with complete success, so that he found himself now but rarely called on to operate for adenoids. He called attention to the fact that the same class of children constantly assumed the several attitudes of rest—namely, the symmetrical and asymmetrical resting postures of the trunk and abduction of the foot—conditions which, when they become fixed or exaggerated, are called by the names "dorsal excoriation" or "round shoulders," "lateral curvature" or "scoliosis" and "flat-foot," all of which terms he hoped would soon disappear from surgery. He described and showed photographs which illustrated the several changes in the trunk which were consequent on respiratory incapacity and the various deficiencies in development of all the bones of the face which he found were directly dependent for their perfect form on the proper evolution of the naso-pharynx under the influence of the forcible passage of air through this cavity in respiration.

WEST LONDON MEDICO CHIRURGICAL SOCIETY—A clinical meeting of this society was held in the society's rooms at the West London Hospital on June 2nd, Dr S D Clippingdale, President, being in the chair—Mr McAdam Eccles showed a boy with a large Nævo lipomatous Tumour of the Forearm which had existed since birth. The case was discussed by the President, Dr Leonard Dobson, Mr Rotheroe, Dr E P Paton, Mr O B Keetley, and Mr Neville Wood—Dr Leonard Dobson and Mr O B Keetley showed a young woman who had been successfully operated on for Gastric Ulcer three weeks previously. The patient had suffered much pain for many months and was in no way better in spite of prolonged medical treatment. Mr Keetley opened the abdomen and found near the œsophagus an ulcer which had become adherent to the diaphragm. The adhesions were separated and the ulcer was scraped and closed. The patient made a good recovery—The case was discussed by Mr Bidwell, Mr Neville Wood, and Dr Paton—Mr Bidwell showed (1) a child on whom he had operated for Tuberculous Peritonitis, and (2) a man on whom he had operated for Extensive Carcinoma of the Rectum—These cases were discussed by Dr Dobson.

Reviews and Notices of Books.

A System of Medicine By Many Writers Edited by THOMAS OLIFFORD ALLBUTT, M.A., M.D. Cantab., LL.D. Glasg., F.R.C.P. Lond., F.R.S., Regens Professor of Physic in the University of Cambridge Vol VI London Macmillan and Co 1899 Illustrated Pp 944 Price 25s net

THE medical profession will welcome the appearance of the sixth volume of Professor Olifford Allbutt's *System of Medicine*. The preceding volumes have contained such excellent articles that the completion of the series is naturally anxiously looked for. The present volume is in every way equal to its predecessors. It contains articles on the circulatory system; diseases of muscles, and diseases of the nervous system.

The first article is by Dr G Newton Pitt on Right-sided Valvular Diseases. Cases of this kind are comparatively uncommon, and Dr Pitt had a difficult task to accomplish in considering them. He has succeeded, however, in producing a most interesting and full account of the affections which may attack the valves of the right auricle

that such a varied number have been recorded. He first writes on "Pulmonary incompetence," remarking that this is the case of the valvular lesions of the heart, only 17 cases having been noted in the past fourteen years at Guy's Hospital out of 11,000 examinations during a period of 23 years. The total number of cases concerned by necropsy which Dr Pitt has been able to collect is 59, besides some 30 cases which were not varied after death. The most common pathological condition met with was infective endocarditis, this being present in 57 of the cases. The subject of Pulmonary Stenosis is merely mentioned, as it is almost invariably congenital in origin and was fully described in vol. p. 100.

Diseases of the Tricuspid Valves are described under five headings—(1) in which acute vegetations were found upon the valves, (2) the valvular cusps were thickened, (3) the cusps were affected with foreign endocarditis, (4) the cusps were incompetent, and (5) the tricuspid cusp was stenosed. This forms a convenient and practical classification. The "safety valve" action of the tricuspid valve is duly commented on, it is of great importance in relieving the strain upon the heart on occasions of sudden exertion.

The article on Atrium Pectus by Sir R. Douglas Powell is written in the usual lucid style of that authority, showing much originality of thought and a thorough knowledge of

his subject in all its details—in fact, he may borrow a sentence which he uses in describing Heberden's work and say that "his description is a model of accuracy and lucid expression." Sir R. Douglas Powell divides cases of atrium pectus into three groups: (1) those cases in which the disease is a pure nervous of the cardio-vascular system, a disturbance of the innervation of the vessels of the heart itself, causing their spasmodic contraction and thus increasing the peripheral resistance to circulation; (2) another and rarer class of cases in which there is the same mechanism of disturbed cardio-vascular innervation, but associated with a diseased heart, and (3) a group of cases in which the heart itself is the primary seat of the fault and often fatal symptoms—the cases include those dependent on coronary artery disease. The first group the author designates "atrium pectus vasomotorium," the second "atrium pectus gastrico or secundario cardiac angina," and the third "primary cardiac angina." This classification is much to be preferred to the one commonly adopted—namely, "true angina pectoris" and "pseudo-angina pectoris," the latter term being both unsatisfactory and round in its significance. The illustrative cases are well chosen and enable the reader more fully to understand the symptoms characteristic of each form.

Dr J. P. Roberts writes on Diseases of the Mediastinum and Thyroid Gland. We have already referred to the remarks on mediastinitis in a leading article in *Chronic Mediastinitis* which appeared in our columns on April 29th. The section on *Inter-thoracic Neoplasms* is particularly interesting and the author has succeeded in compiling an admirable review of the subject which, added to his own experience, makes the article a valuable one. The clinical aspect of the subject is fully described in terms which leave no room for doubt as to the writer's meaning, especially so in relation to diagnosis.

Under the heading Diseases of Blood Vessels and Lymphatics are several conditions: Thrombosis and Embolism, by Professor Welch, Philadelphia, by Mr. H. H. Clifton, Army or the Army, by Professor Sir W. T. Gallie, and Abnormalities of Arteries in the Abdomen by Dr Rolleston, the last named also contributes a paper on Diseases of the Lymphatic Vessels.

One of the best articles in this volume is that on Aortic Aneurysm by Sir W. T. Gallie. It is characterized by a masterly knowledge of the subject and a manner of expressing his ideas which at once rivets the attention of the reader. In speaking of the mechanism of origin of aneurysms of the aorta the author points out that we have to deal with an exceedingly complicated problem and that while it is in a high degree reasonable to affirm that both continuous effort and sudden or violent strain or injury are in a very appreciable degree causes of aneurysm, the question of how far and at what stage is a particular case these causes have come into operation is often one of the utmost difficulty and complexity. The symptomatic diagnosis is elaborately set forth and the actual value of certain symptoms are considered at length, these being pain, cardiac collapse, syncope, palpitation, cough, dyspnea, large pulsations, hæmorrhage, and dysphagia. Space will not permit us to comment further on this most valuable contribution, but both author and editor may be congratulated on its appearance.

Under the section of Diseases of Muscles are four papers, one on Myositis, by Dr Ba'ten; one on Myositis Congenita (Thomson's disease), by Dr Hale White, one on Idiopathic Muscular Atrophy and Hypertrophy, by Dr C. B. Heer, and the last on Focal Hemiatrophy and Hemiplegia by Dr Aldren Turner.

Diseases of the Nervous System are then commenced, the first article being by Mr Bryan Lewis on General Pathology of the Nervous System. Our knowledge on this subject has so much increased during recent years that Mr Lewis had a hard task before him to select and describe the more important discoveries in the physiology requires careful and close reading but contains a large amount of information. He begins by describing the "nervous," the modern conception of which, as that of a relatively continuous protoplasmic continuum—the cell body enclosing a nucleus of relatively large size and a well defined nucleus. The "axon" and the "dendrons" are then fully understood by the majority of readers. A general view is then taken of Systemic Diseases, and we are told that "by this term we mean the extensive implication of nerve tracts having a commonality of function of certain types in the chain of neurons which extend from the periphery to the brain cortex, or conversely." The expressions "higher level motor neurons," "motor neurons of the lower level," and "combined system diseases" are also briefly explained. Another excellent article is by Professor Sherrington and Dr. Sharkey on Tremor, Tension Rhegmenism, and Spasm, the former author being responsible for the physiological section and the latter for the clinical and pathological sections.

Next follow articles on Trophic Nerve Diseases. Neurotrophic Affections of Bones and Joints, by Dr. Unwin, Neurotrophic Diseases of Soft Tissues, by Mr. J. Hopkins, Adipose Deposits, by the Editor, Raynaud's Disease and Erythromelalgia, both by Dr J. Barlow. Want of space prevents us from commenting on the above, but they form a most valuable series of articles for reference.

The next division is headed Diseases of the Nerves and contains the following articles: Diseases of the Spinal Nerves, by Dr G. A. Gibson and Dr R. A. Fleming, Multiple Sclerosis, by Dr G. A. Gibson, Diseases of the Cranial Nerves, by Dr Aldren Turner, and Medical Ophthalmology, by Mr. Brudenell Carter. The contribution on Diseases of the Spinal Nerves reflects the greatest credit on the

authors, they having condensed an immense amount of work into a comparatively small space. The consideration of the subject (after a short introduction) is divided into two groups, one of a more general character containing the pathological and clinical features common to the different forms of disease, the other of a more special character.

The subjects which fall under the head of "general features" are neuritis, tumours, pressure, and wounds, whilst under the "special section" are described the individual affections of the different nerves. This division is a convenient one both for study and reference.

Under the title "Diseases of the Spine" are two contributions—Diseases of the Vertebral Column, Tumours, and Compression Palsies, by Mr Victor Horsley, and Affections of the Spinal Meninges, by Dr J S Risien Russell. Mr Horsley's paper, as might be expected coming from an author who has made the subject one of particular study, is full of valuable information but is essentially practical, a quality which the majority of those who consult the "System" appreciate above everything else.

The last article in this volume, by Dr Risien Russell, also shows that much pains have been taken in its production and that the author has had a practical acquaintance with the diseases which he describes. The main part of the paper is occupied by a consideration of the most important morbid conditions of the spinal meninges—(1) vascular disturbances, (2) inflammations, and (3) tumours of the meninges. Dr Russell adds, however, "Besides these conditions there are certain morbid states which are only of interest from the pathologist's point of view and concern us but little as they give rise to no clinical manifestations by which they can be recognised or which call for treatment." These are very wisely disposed of in comparatively few words.

In conclusion, we must once more congratulate the editor, Professor Clifford Allbutt, on his choice of the authors and the manner in which they have fulfilled the duties entrusted to them.

Nauheim, Its Springs and Their Uses, &c. By J GROEDEL, M D, Bad Nauheim. Friedberg and Bad Nauheim. Bindernagel 1899.

THAT a second and enlarged edition of Dr Groedel's guide-book should be in demand within four years of the publication of the first edition shows that it has supplied a public need. The statistical record of the growth of Nauheim as a watering place is an interesting study. For the 30 years from 1855 to 1885 there was an average influx of between 4000 and 5000 visitors annually. In 1890 the numbers had risen to over 8000, in 1895 to over 14,000, and in 1898 to over 19,000 persons. This later era of "leaps and bounds" in prosperity coincides with its wide advertisement as a resort for the treatment of chronic heart disease. The author, as one who has had a long experience of the use of the waters of Nauheim, is entitled to speak with authority on the subject. The volume before us is at once a guide to the springs and their uses and to the town and the surrounding country easily accessible to the visitor. To combine these objects satisfactorily is no easy task and one demanding considerable professional and general tact. To attempt it, moreover, is to undertake a considerable responsibility. Opinions must be well weighed and the limitations and dangers as well as the beneficial effects of the waters in question must be fairly set forth if a public ignorant of medicine and aware only of their sufferings are not to be misled or disappointed. We consider that Dr Groedel has been very mindful of these difficulties and responsibilities and that he has acquitted himself of his task with much judgment and impartiality. The section to which our readers will chiefly turn is that dealing with "the diseases for which Bad Nauheim is adapted and their treatment." We observe that

while giving due prominence to the aqueous therapeutics of these maladies Dr Groedel has not been unmindful of the general treatment of disease based upon the principles of physiology and pathology which remain the same whatever the geographical position of the patient. It is this circumstance which renders the physician himself not the least important factor in the efficacy of a given health resort. The author states, however, with much truth, that excellent remedies applied at the homes of patients at times seem to require the additional sojourn at such a resting place as Nauheim to exercise their full force. Nor is it surprising that this should be so. The influence of a pleasant and invigorating watering place, far from the scene of the daily anxieties and the half performed duties of one enfeebled in health, is a potent factor for good. To all such influence the author gives due weight and with respect to the direct effect of the waters and climate of his own town writes with a conviction of their utility under appropriate circumstances and also with a commendable caution. The work is written in English by the author himself and shows a good knowledge of our language. Some idiomatic errors occur which are of no great moment and may be corrected in a later edition. The book is well printed, is of a convenient size and affords useful information both to the professional and the lay reader.

The Thermal Waters of Bath. By GILBERT A BANNATYNE, M D Glasg, M R C P Edin, Honorary Physician to the Royal Mineral Water Hospital, Bath, and to the Royal United Hospital, Bath. Bristol John Wright and Co. London Simpkin, Marshall, Hamilton, Kent, and Co., Limited 1899. Pp 87. Price 2s.

THIS little volume gives a good account of the thermal waters of Bath, the appliances for their use and the diseases in which they are employed. One feature of the book at once strikes the reader—viz, the very moderate tone in which it is written—it is not merely a "puff" of the city in which the author practises. Bath is given its due meed of praise but no more. This is as it should be and it is more likely to redound to the credit of the baths than exaggerated commendation. The first chapter deals with the historical associations of the baths, with a brief consideration of the situation, the climate, and the general health statistics of Bath. The second chapter is devoted to the source and origin of the waters and a comparison with other springs. The author also gives some attention to the theory of the action of the waters and arrives at the conclusion that it is not to the presence of one or more particular mineral ingredients, except when they are found in large quantities, that the efficacy of any spring is due or because of which it is selected as a medicinal agent, but it is rather to the union of the several substances contained in the water and to its temperature that we may look for the benefit which the combined experience of those prescribing it and of those using it would teach us to expect. With this theory most spa physicians would probably agree. It is because the "combination" in which the various mineral and gaseous constituents exist in such waters is unknown that we are unable to successfully imitate them and bring Bath, Homburg, or Nauheim to London. In the third and fourth chapters will be found a clear and detailed description of the bathing establishments, stress being laid on the fact that they are open all the year round. In describing the Aix massage douche baths he takes the opportunity of giving a short dissertation on massage and its uses. In the chapter on the action of the baths in diseases in which the waters are of use the author again exhibits the thorough scientific knowledge which he possesses of hydro-therapeutics. With regard to the diseases most satisfactorily treated by a course of the baths, gout and rheumatism of the

those bacteria which are pathogenic in the human subject which was commenced in the volume for 1898 is completed in the present volume, it has been prepared by Mr S. G. Shattock and is excellent. This work should prove of especial benefit to those who are in general practice, for it gives them the most recent information and it will often provide a suggestion for treatment at the very moment when it is needed. There are useful appendices on recent legal decisions affecting medical men, on new medical appliances, and lists of new books and of asylums and infirmaries homes. There is also an index to life insurance offices and in each case is given the amount of premium for insuring £100 at 30, 40, and 50 years of age.

The Hygiene of the Mouth. By R. DENISON PEARCE. London: J. F. Sells and Co. Philadelphia, U.S.A. Price 2s 6d.—The object of this little volume is to show how dental disease may be controlled and in a large measure prevented. It is somewhat difficult to discover for what class of readers the book is intended. Some portions are well worthy the attention of those specially engaged in medical work, while in many portions the elementary character of the information would serve to indicate that the book is intended for the lay reader. Still, anyone not actually engaged in dental practice will gather much useful information from the little work and if it only helps to teach in a small way the importance of maintaining the mouth in a healthy condition it will not have been written in vain. We may say that in the "get up" of the book there is room for considerable improvement.

LIBRARY TABLE

Annual and Analytical Cyclopædia of Practical Medicine By CHARLES E. DE M. SARGENT, M.D., and 100 Associate Editors. Vol. III. Pp. 600. Illustrated with chromo-lithographs, Engravings, and Maps. Philadelphia, New York, and Chicago: The F. A. Davis Company. 1899.—We have already commented on the general objects and scope of this work in our reviews of the previous volumes. The present volume commences with an article on Dislocations, better known in this country under the term "wrethism." All the papers are well written and are of such length as to enable the authors to give a fair amount of space to their subjects. In certain instances, however, as when the pathogenesis is obscure or recent investigations have rendered more space desirable, writers have been allowed such latitude that their articles form valuable monographs. Amongst such more extended contributions are the following: the article already mentioned on Infantile Myocardium, by Professor Osler and Dr Norton of Baltimore, Exophthalmic Goitre, by Professor Putnam of Boston, and Goitre, by Professor Adam of Montreal. From the numerous subjects appearing in this volume it is a little difficult to select any for special notice. To the surgeon the following will be of interest: Dislocations and Fractures, by Professor Blumson and Dr Keefer, Jun., of New York, Hip-joint Disease, by Dr Reginald H. Bayre of New York, and Hernia, by Dr W. B. Coley of New York, whilst the attention of physicians will be more attracted by the papers on Dysentery, by Dr Klemmer of Baltimore, on Gout, by Dr Levinson of Copenhagen, on Rheuma, by Professor Stejneger of Philadelphia, on Hysteria and Hypnotism, by Professor Kitzig of Denver, and on Ratty Degeneration of the Heart, by Dr J. M. Anders of Philadelphia. The contributions have all been well brought up to date, the literature of 1898-99 being freely referred to.

The Medical Annual and Practitioner's Index. For 1899. Bristol: John Wright and Co. 8vo. Pp. 734. Price 7s 6d. net.—For 17 years this useful annual has appeared, and although the first volumes were good the later volumes have been even better, so that at present the book can be accepted as a trustworthy record of the advances made in medicine, surgery, and gynaecology during the past year. Every year it must become increasingly difficult to compress into a reasonable compass the vast amount of fresh information which accumulates unceasingly. The work deals with advances not only in treatment, though this has most space allotted to it, but also in etiology and diagnosis, and the names of the contributors guarantee the trustworthiness of the information supplied, and as the sources are quoted the reader knows where to refer should he need further information. Numerous illustrations, both plain and coloured, assist the text and the printing and paper are all that could be desired. The series of plates illustrative of

Annuaire de Gynécologie et d'Obstétrique May, 1899. Paris: G. Steinheil.—This number contains the following original articles: The Treatment of Uterine Cancer by Total Abdominal Hysterectomy, by M. L. Picoué and P. Manchac, the Vascular Ligaments of the Uterus, by M. Pierre Friedel, and the Employment of Silem in Gynaecology and Obstetrics, by Dr R. Labrousse. A review is given of the theses by Dr Ch. Lefèvre, on a Common Form of Sterility in the Female. An account of the proceedings of various gynaecological and obstetrical societies and the usual bibliography conclude the number.

NEW PUBLICATIONS.

AN ADJUSTABLE READING DESK.

This desk consists of a board measuring 11 inches by 13 inches provided with three props or supports which enable it to stand securely in a sloping position at any angle that may be desired by the reader. The attachment on the other side there is a T-shaped book-holder pivoted on a short brass rod passing through the centre of the board. The book holder can be turned in any direction round this pivot and can be clamped at any point so that the book may be placed in the usual upright position or may be placed so as to be conveniently read by a person lying on his side, in which case it is fixed to the book holder by two cords passing inside the covers and the pages are held open by brass hooks. The desk has in fact been designed for use by students, invalids, and others who are desirous of reading when lying on the side in bed or elsewhere. It is no less useful for readers seated at a table in the ordinary way, as the book is conveniently supported and held open. Provisional protection has been taken out for the desk, and it may be obtained from Mr E. H. B. Hughes, Howlands Hey, Bea Bank road, Leicester, Cheshire.

THE LANCET.

LONDON SATURDAY, JUNE 10, 1899

THE celebration of the centenary of the Royal Institution is an interesting historic as well as scientific event. During the period of its existence the achievements and progress of science have been unprecedented. It would not be correct to say that the whole fruits of scientific research in this country have been due to the work done in the Royal Institution, but there can be little doubt of the great good and influence which the foundation of the Institution has exerted upon educational progress. Whatever may have been the primary objects of the foundation of the Institution, it has since fulfilled a most worthy and admirable function in serving as a means of promulgating exact knowledge amongst the people. It has served, in short, as a connecting link between the people and the profound scientific thinker and investigator. Nor has this position been reached at the sacrifice of the best traditions and aims of the Institution, for although at one time it threatened to become the mere playground of science the demonstrations held within its walls have stirred up in some who deemed it fashionable to attend the lectures in its early days a spirit either to go on with the work of unravelling Nature's mysteries or else to assist materially the funds of the Institution so that others might be enabled to carry on that work which plays no unimportant part in the welfare of the nation. Where else can the people go who are interested in seeing and understanding the recent developments of scientific research and who have a natural yearning to comprehend its import and to be in a position to speculate upon the probable application of discoveries to commerce, to hygiene, and even it may be to the preservation of peace? Of those, for example, who attended the lectures of that brilliant investigator and exponent, MICHAEL FARADAY, it is probable that many foresaw how important the application of his delightfully simple and lucid experiments and demonstrations was likely to be in the affairs of the civilised world. For in those experiments were the elements of modern lighting by electricity and of human communication by telephony and by telegraphy. Many will remember the apparently simple experiment which has since proved so momentous—the revolution of a metal disc opposite the poles of a magnet giving rise to an electric current. The same experiment has been a million times repeated on a practical scale and to-day it finds illustration in the powerful dynamo upon which we depend at present as the best source of energy for the production of the electric light. For 50 years FARADAY laboured within the walls of the Royal Institution and his labours are a tribute to its founders and a monument to his genius.

The Royal Institution was founded by Sir BENJAMIN THOMPSON, better known as Count RUMFORD, in 1799;

himself a prolific contributor to our knowledge of physical laws. Count RUMFORD, however, was not long at the Royal Institution and at the time when he left the revenue was so low as to threaten an untimely end to the foundation. Odd as it may appear, the Institution was saved by people of a purely business instinct, whose avowed object was to "run" the Institution on somewhat commercial lines and to bring scientific experiments to the fore as a fashionable sort of thing to talk about. This may have been a derogatory procedure from the point of view of pure science, but it succeeded in preserving the Royal Institution for uses that proved far from base. It was at about this critical juncture in the history of the Royal Institution that Sir HUMPHRY DAVY commenced his duties as a professor there, with what result is well known. Young DAVY was a surgeon's assistant, but his bent was towards chemistry and physics, on which subjects he proved himself an able investigator during his engagement at the Pneumatic Institution at Bristol which he joined soon after its foundation. It was here that he discovered the anæsthetic properties of nitrous oxide, but his most memorable work was done in the Royal Institution where he isolated the metals of the alkalis and alkaline earths by the galvanic current. Sir HUMPHRY DAVY did probably more than any of his contemporaries to awaken the public interest in the application of chemistry to technical industries and daily life. It is pleasing to record that the nobility and poetry of Sir HUMPHRY DAVY's nature are shown in his writings and in his beautiful relations with FARADAY who succeeded him. The work of FARADAY has since been carried on by men who are happily amongst us at the present day. It was in the Royal Institution for example, that Sir EDWARD FRANKLAND carried on that classic research on organo-metallic compounds which led to the theory of types and which has since proved a solid basis for that huge superstructure now known as organic chemistry. Distinguished chemists like Dr ODLING and Dr GLADSTONE also occupied the same professorship until in 1877 the present holder of the chair, Professor DEWAR, was appointed. The chair is known as the Fulleren Professorship and was founded by JOHN FULLER in 1833. This was the first substantial endowment to the Royal Institution, the sum of £10,000 being disbursed in maintaining a chair of chemistry and physiology and the balance used as a reserve fund.

Professor DEWAR's splendid researches and results in the liquefaction of gases are well known and are of historic interest since this work was really commenced by FARADAY. With what admiration would FARADAY have witnessed the liquefaction of air, fluorine, helium, argon, and hydrogen, and how profoundly impressed he would have been with the triumph, coming as a sequel of the researches which he had begun, the conversion of all known gases under the combined influence of high pressure and low temperature to the state of liquid and incidentally in some cases of solid. Of the distinguished physicists who successfully devoted much of their time to research at the Institution must be mentioned that able experimentalist and exponent JOHN TYNDALL. He was succeeded by Lord RAYLEIGH, an able mathematician whose name has become recently familiar to the world by his observation of the

We here limit our remarks to one only among the many important matters which are treated of in its pages

To the medical officer of health the difficulty—we had almost said the impossibility—of obtaining an accurate measure of the death-rates or the reverse of the people under his jurisdiction is one of the most embarrassing of the many obstacles which still retard progress in practical sanitation. The local registrars, for the most part, supply fairly accurate returns of the deaths occurring from time to time in their districts, but when these have been duly abstracted by the health officer and properly distributed so as to allow for mortality in public institutions there remains the almost insuperable difficulty of ascertaining, even approximately, the population upon which these deaths have to be calculated in order to furnish trustworthy statements of mortality or, as they are commonly termed, rates of death per 1000 living. It is needless to point out that this difficulty increases year by year as the census becomes more remote. On Dr Hore's authority we learn that this difficulty has become exceptionally great in Liverpool where, either because of the recent enlargement of the city or for other reasons specified in his report, the population of the city as at present constituted is, in his judgment considerably understated in the published returns of the Registrar General. Dr Hore further complains that having himself applied to certain small municipal areas of Liverpool the method which the Registrar General employs for the estimation of the populations of some of the larger urban centres in their entirety, he obtains populations which make the birth- and death rates of those areas appear enormous, a result especially deplorable because these are the very districts in which Dr Hore has succeeded in securing the largest amount of structural improvement by the sanitary authority, and he is not unnaturally disappointed to find that, on applying the only available test, the death-rate, he is unable to demonstrate such an amount of amendment as might have been hoped for after the large expenditure which has been incurred on account of demolitions and alterations of insanitary property. With regard to the method adopted at Somerset House in estimating the populations of the great English towns there is no mystery whatever. Except in special cases, to which reference will presently be made, it is the practice of the Registrar General to assume that the same annual rate of growth of population which is known to have prevailed in each town during the 10 years intervening since the last two censuses has continued uninterruptedly since that period. Accordingly, a proportionate addition is made annually to the population of each town and the number so obtained is taken to represent the population at the middle of each year. In certain instances, however, special circumstances have arisen locally which have interfered with the uniform movement of the population; and in such cases the Registrar-General has usually been willing to consider local representations to that effect, and in suitable cases where returns of inhabited houses have been forthcoming to revise the estimates of population of particular towns for which the estimates framed in the usual way have been shown to be erroneous. We know of instances in which this has been done, and it is probable that in the case of Liverpool referred to in Dr Hore's report it is similar

abnormally shown in the density of the nitrogen of the air—an observation which, with the assistance of Professor RAYLEIGH, led to the recognition and isolation of a new element, argon. This discovery marked an epoch in the history of both chemistry and astronomy. It has opened up an enormously wide field for conjecture and research and has already been prolific in yielding fruitful results. The last event of importance in the just closed century's history of the Royal Institution is the munificent bequest made by Mr LUDWIG MAYER in 1898 which provides for a permanently endowed DAY FARRADAY Research Laboratory which is thoroughly equipped for the prosecution of research by all qualified workers who choose to apply. The actual centenary date of the founding of the Royal Institution was last Monday, June 5th, on which occasion the PRINCE OF WALES presided over a banquet held at the Merchant Taylors' Hall and during the week commemoration lectures were delivered by Lord RAYLEIGH and Professor DEWAR, while a reception fully in keeping with the importance of the occasion was held by the Lord Mayor and was attended by a very distinguished company of scientific workers including foreign savants. It will be admitted that the history of the Royal Institution is full of interest. Its existence from its foundation has had much in common with human career. It was at first devoted to a mission which failed it was threatened again and again with extinction from the want of material support, nevertheless it has come out triumphant, as an institution with worthy objects and with praiseworthy results, and has been sustained financially in order to carry on its excellent work by those generous and rich men who have been moved by, and convinced of, the real educational and progressive work which it has done and continues to do. The Royal Institution affords a striking illustration of that proud characteristic of the English nation which prompts it to support all that claims to be philanthropic and devoted to the best interests of the community and this apart altogether from State aid. It has been said that the Germans are a long way ahead of us as a nation in the application of science to manufacture and industry. That may be so, but in regard to original research and the wealth of results therefrom England still holds, and proudly holds, the first position and thus has attained and maintains by voluntary support. The Royal Institution is a noble instance of the sanctity of this national characteristic and the dawn of its second century will doubtless bring, as we confidently anticipate, further encouragement and stimulus to carry on its excellent work and purposes.

We have received a copy of the interesting report which Dr Hore has recently presented to his sanitary authority on the health of the city of Liverpool in the year 1898—a document which extends to 217 closely printed pages and is full of valuable information concerning the sanitary condition of that city, with special reference to the steps which, under Dr Hore's guidance, the corporation has taken for the improvement of local birth and death rates, as set forth in the report, we shall deal on another occasion.

course would have been pursued about the middle of the last intercensal period had the necessary particulars from the rate-books been supplied to the central office

We are very glad to recognise the ability and zeal which Dr HOPE has for many years displayed in his attempts to improve the sanitary condition of the vast population of Liverpool, but we are confident that he errs in thinking that the immediate remedy which he suggests to meet his own special case would be suitable for general adoption. If we correctly understand Dr HOPE's proposal it is this—that the Registrar General should issue official estimates, even at this long distance from the census, for each of the 11 municipal subdivisions of Liverpool, the population of which ranges from about 16,000 upwards. Statisticians are, however, agreed as to the impracticability of estimating prospectively the population of small districts on the assumption of a constant rate of increase or decrease, and for periods as far remote as the present from the census the attempt to do so would be absurd. At any rate, it is the fact that the Registrar General has always consistently refused to estimate for anything short of the entire populations of urban districts and in so doing we think that he has acted wisely. Having regard to the exceeding length of the interval between successive census enumerations it is beyond question that the method of the Registrar General has hitherto given results which are in most cases satisfactory, and under existing circumstances we know of no other plan which would be likely to prove superior. It has frequently been contended in these columns that the difficulty which besets Dr HOPE and his colleagues in the public health service will never be surmounted except by a more frequent numbering of the people. We therefore agree with him in advocating recourse to a quinquennial census for the whole country, simple in character and similar to that which has been established by recent legislation for the metropolis. This course has recently been urged on the President of the Local Government Board by the Council of the Royal Statistical Society and we are of opinion that the expense inseparable from a more frequent enumeration should no longer be permitted to stand in the way of social and sanitary reforms which are believed to be necessary by those who have the best title to be heard.

THE work of the London medical societies for the year 1898-99 is now approaching its close and indeed several of these learned bodies have already discontinued their sessions until October next. The time therefore seems opportune to draw a moral from the experiences of the past year. And let us start by saying that it would be difficult to exaggerate the value of our medical societies not only to the London medical man but to his brother of the provinces. The work which they do and the careful way in which they do it alike excite our admiration. They stimulate young members of the profession and they enable the older ones to see the drift of new light and new investigation. Their importance is universally recognised. They are no longer the monopoly of the metropolis and of its central parts, but they are to be found in every provincial town of any size. A casual visitor from London

at one of the meetings of a provincial medical society—say, at Newcastle, Leeds, Nottingham, Manchester, or Liverpool—is apt to be astonished when he considers the cases which are brought forward and the skill with which they are diagnosed, treated, and discussed. There may or there may not be room for a post-graduate school in London and in other large and central towns, but undoubtedly the chief post-graduate education which medical practitioners get is in the medical societies and in the medical journals which devote an ever increasing amount of space to the reports of their proceedings. We have said enough to show that we write in no depreciative spirit of the medical societies and that we desire to promote only their increased usefulness and support. But there exist as regards such societies certain defects to which we wish to call attention.

For one thing, in the London medical societies we should desire to see a larger attendance. Even in the best societies and on what may be called field nights the numbers are disproportionate to the importance of the papers and to the time and trouble which have been spent by the gentlemen who have prepared them for the consideration of the society. This is partly due doubtless to medical journalism. Members of the profession know that in their medical paper they will find the chief points of all the communications recorded with faithfulness and accuracy. Still, we cannot think this explanation altogether satisfactory. There are two kinds of absentees at the London societies. The first consists of the older and more eminent members of the society who having filled all the offices and attained a success in practice which leaves them little leisure are apt to prefer their own firesides when it is time to go to the society. It is hard to blame them. But even they would be a little more frequent in their attendance if they knew how their presence is appreciated and how pleasant it is to the members generally to hear the cases and the conclusions of younger colleagues discussed in the light of a longer and a larger experience. The disappearance of past presidents and honorary secretaries is often painfully abrupt and complete, as if the efforts of office had exhausted alike their energy and their interest in the society which they serve so well for two or three years. Perhaps the only cure for this defect of our metropolitan societies would be a diminution in their number. It is not in human nature to attend medical societies every night in the week and such attendance cannot be given in these busy days without serious neglect of other duties. Even if it could, the benefit would be very questionable. No professional man does well to act as if his profession covered all truth and duty. It is well for him to seek the society of men of other professions than his own and to give as much of his evening time to domestic duties as can well be spared. Clearly if the number of our medical societies were greatly reduced it would be more possible for busy men to attend with comparative regularity without encroaching on time necessary for the other large duties of life in this busy age.

The other noteworthy absentees from our metropolitan medical societies are the great body of general practitioners. Many explanations of this fact may be given. The duties of general practice are not over so soon or so

definitely as those of the consulting practitioner. They are often as hindering in the evening as in the morning. Another reason is to be found in the great multiplication of local societies. It is remarkable, as we have said, to what an extent this process has gone, so that in some suburbs there are two or three medical societies which are easy to reach and the proceedings at which are a little more social and less formal than those of the more central societies. It has appeared to some critics that our great societies are a little too strict and formal in their style and that they are open to the charge of dealing too exclusively with rare cases and difficult subjects. They abstain too severely from discussing those questions which deeply concern the rank and file of the profession and which affect the dignity and the reputation of medical practice. The removal of a stomach, the suturing of a heart, or the cure of an abdominal aneurysm are, no doubt, great feats, but they are of rare occurrence and constitute but a fraction of the work of medicine. They do not appeal to the general practitioner so much as the treatment of influenza or pneumonia, the pathology of headache, or the treatment of infantile diarrhoea. To this class of practitioners, too, there seems to be in the larger medical societies a serious want of interest in the evils which affect medical practice—such, for example, as hospital abuse. An enormous amount of good might be done by instituting an occasional social evening when men of all grades of practice might unband and discuss with each other in informal ways the problems of medical life among the poor with a joint view to their welfare and to the dignity and efficiency of medical practice. The sum of what we have said is this—that medical societies are amongst the best agencies in the profession, but that they could be made more useful and more attractive by becoming fewer and by such an occasional relaxation of their severity as would bring them into touch with the whole medical profession and the whole experience of medical life.

THE BIRTHDAY HONOURS AND THE MEDICAL PROFESSION

"No quid nimis."

Annotations.

The birthday honours, contrary to general expectation, are neither numerous nor distributed with any special reference to the eightieth birthday of the Queen. There is no great recognition of personal services to the Crown, there are no new Fests, no promotions in the Peerage, and no new Privy Counsellors. For the most part the honours were what may be called perfunctory, that is, they take the form of decorations. Two eminent physiologists and a well known practical surgeon are the only members of the medical profession who receive titular distinction. Professor J. S. Burton Sanderson, for many years Waynflete Professor of Physiology at Oxford and now Professor of Medicine at that University, becomes a baronet. Professor Michael Foster, the equally famous head of physiological teaching at the sister University of Cambridge and secretary to the Royal Society, receives a K.C.B. Mr. William Mitchell Blake, the popular and able Liverpool surgeon, obtains the knighthood to which his excellent work as surgeon and teacher including the preliminary scintillating at the London University was the first institution.

in Liverpool and as a representative of the Victoria University in the General Medical Council entitles him Surgeon General A. A. Gore, late Principal Medical Officer in India, receives a C.B., and Lieutenant-Colonel W. G. King, I.M.S., a C.I.E.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The names of candidates for the vacancies in the Council of the Royal College of Surgeons of England must be sent to the Secretary not later than June 12th. Any proposals to be placed on the agenda for the annual meeting of Fellows on July 6th must be sent to the Secretary by June 15th. It will be remembered that in 1898 no quorum was formed at the January meeting of Fellows and therefore that meeting was abolished, yet no quorum was formed at the July meeting. As only one meeting is to be held annually in future it is surely possible to obtain the attendance of the necessary 30 Fellows. If repeated failures to obtain meetings occur the Council will not improbably decide to alter the by law under which the meetings are at present summoned.

THE MEDICAL EDUCATION OF WOMEN

As several inquiries have reached us respecting the medical education of women the following information may be useful. In the first place no woman ought to embark on the career of medicine without a reasonable certainty of having sufficient capital, not only to pay for her training and keep her during at least five years of student life, but also to support her for the first few years after qualifying. Paid appointments for newly qualified medical women are few and far between. To women who are being sent out under the auspices of some society to India or elsewhere and are certain of immediate employment this does not so much apply, but even in these cases it is as unwise for a girl to start as a medical student unless she is sure of sufficient money to keep her without doing outside work and to allow of a good yearly holiday during her period of study. A medical student ought to have time to devote to her own support. She should be able to take good holidays without worry about money matters or her health will probably break down and she will be useless even if she succeeds in passing her examinations. As regards age, 20 years is quite young enough to begin the medical portion of her training. She should have a thoroughly good general education until she is 18 years of age, when she ought to be able to pass any of the preliminary Arts examinations required before she can proceed to her medical work. The best of these Arts examinations from the medical student's point of view is the matriculation at the London University. The next two years might be profitably employed in acquiring a thorough knowledge of French and German, preferably by residence abroad, and of drawing, skill in these three branches and some knowledge of the ways of the world would be of great value to her. She would then begin her medical work as a more or less accomplished and well educated woman and not as a raw schoolgirl. The choice of a medical school depends in some measure on the degree or diploma which the student means to take. The best medical qualification open to women is the degree of the University of London. The best place of study for a woman who aims at the London degree is unquestionably the London Royal Free Hospital School of Medicine for Women. This school admits women students only. It is thoroughly well equipped in every department and its students receive full instruction in all subjects required in the medical examinations. Popular and able Liverpool surgeon, obtains the knighthood to which his excellent work as surgeon and teacher including the preliminary scintillating at the London University was the first institution.

eight day the temperature suddenly rose to 104°, the features became immobile, and the eyes did not blink when the fingers were passed before them. The pupils were widely dilated and almost insensible to light, the jaws were closed, there was grinding of the teeth, the head was retracted, and the upper limbs were rigid and extended. The lower limbs were flexed. The thighs, which were drawn up, were extended with ease when the child was lying down, but with difficulty when she was sitting (Kernig's sign). The respiration was irregular. There were signs in the chest of recrudescence of the pneumonia. The signs of meningitis increased, the child was unconscious, the pupils were large and insensitive to light, the stiffness of the neck increased, and the rigidity of the limbs was permanent. The patient gradually recovered, the temperature became normal on the fifteenth day but the rigidity of the limbs persisted in some degree until the twenty-fifth day. M. Rendu did not doubt that the pneumococcus was the cause of the otitis and adenitis in the first case. The onset was identical in all three cases and was that of pneumonic invasion—a violent rigor, followed after some hours by marked pyrexia.

THE WHITE LEAD INDUSTRY

Six years ago a departmental committee was appointed by the then Secretary of State, Mr. Asquith, to inquire amongst other things as to whether the special rules which existed with regard to the manufacture of white lead were sufficient and to suggest any precautions necessary with regard to the industries specified for the protection of life or health. The committee was composed of several able men and their report, which was issued in a Parliamentary paper towards the end of 1893, contained a summary of suggestions and recommendations of great promise from the point of view of improving and protecting the health of the operatives while as little as possible interfering with the legitimate pursuit of an indispensable manufacture. No serious State action appears, however, to have been taken to apply the recommendations of this committee, for last week the Home Secretary placed upon the table of the House of Commons, according to the *Times* of June 3rd, a paper containing 35 special rules which are proposed to be applied in future to all white lead factories, and these special rules embody the recommendations of Mr. Asquith's Lead Committee with, however, some important additions. The special rules affect occupier and employé alike. The plans of all white lead factories which it is proposed in the future to construct are to be submitted to, and approved in writing by, the Chief Inspector of Factories. Emphasis is very properly laid upon the necessity of keeping as far as possible, as was enjoined by Mr. Asquith's committee, the machinery and chambers involved in the manufacture of white lead moist. Similarly also occurs a recommendation to the effect that no woman should be employed in the white beds, the rollers, the wash beds, the stoves, or in packing dry white lead, and that these departments should be worked in future only by adult males. We are glad to note that more stringent measures are to be imposed providing for more regular and systematic medical examination. A duly qualified medical practitioner must be appointed for each factory and no person is to be employed in a lead process for more than a week at a time without a certificate of fitness granted after examination by the appointed surgeon. Each employé is to be examined once a week and his suspension may be ordered by the surgeon whose sanction is further necessary before he can return to work. Finally, when an employé complains of feeling unwell the occupier is bound instantly to give an order upon a duly qualified medical practitioner. Certain duties are similarly to be imposed on the workers

They are to present themselves regularly at appointed times for examination, they are to wear an overall suit and in some cases a respirator, they are to bathe regularly and wash in the lavatory before bathing, and, lastly, they are not allowed to smoke or use tobacco in any form or partake of food in any other but the properly appointed place. In the main, therefore, the special rules which the Home Secretary has recently drawn up simply give effect to recommendations which were made some years ago. As we have said, however, there are one or two amplifications and we trust that since sufficient time has elapsed to enable all the parties concerned to express an opinion upon the practicability of these recommendations the special rules will ere long be adopted and thus minimise, if not remove completely, the dangers incident to the manufacture of white lead.

MEDICAL CERTIFICATES AND THE SCHOOL BOARD

A CORRESPONDENT writes from the country to ask the following question: "Has the School Board the power to pay for certificates for non attendance at school due to sickness, and if so what fee do they allow the medical man?" We do not know whether a provincial School Board will be willing to consider the action of the London School Board as a leading case, but on Jan. 21st, 1897, the following motion proposed by Mr. Whiteley and seconded by Mr. A. Riley was agreed to: "That in cases where the magistrate or justices of the peace is or are dissatisfied with the medical certificate furnished, and in cases where the medical certificate is *prima facie* unsatisfactory (and when the certificate is signed by a registered medical practitioner), the board's medical officer shall in the first instance communicate with the practitioner giving the certificate and in the event of such certificate being ultimately acted upon the fee of 2s. 6d. shall be paid by the board for the confirmation of such certificate." So far as we know payments made under this law have never been questioned by the auditor in auditing the accounts. Therefore, it is plain that a school board has the power to pay a medical man a fee and if under one set of circumstances why not under others? If the London School Board can do so why not a rural board? They are both under the same master namely, the Education Department.

THE MANCHESTER SEWAGE PROBLEM

THE Mersey and Irwell Joint Committee proceeded against the Manchester Corporation last week before Mr. J. M. Yates, Q.C., stipendiary, and other justices in the Manchester County Police Court "for knowingly permitting liquid sewage to be carried into the river Irwell and the Manchester Ship Canal contrary to the provisions of Part 2, Section 3, of the Mersey and Irwell Joint Committee Act, 1892." It appears that on July 25th, 1896, the first order of the court was made and the case had been dragging on ever since. In November, 1896, the court ordered the corporation to establish sewage works within 12 months. On Nov. 26th, 1897, the corporation made a further application to the court for the order to be extended till March 25th, 1898, the case being adjourned till May 11th, when the application was dismissed. Summonses were issued on May 17th, 1898, and on July 20th the court granted by consent a further adjournment for six months, and it was understood then that if the corporation would get a scheme approved by the Local Government Board penalties would not be asked for, and towards the end of that six months the Rivers Committee of the corporation received from three eminent experts a report showing that the bacteriological treatment would be efficacious. An inquiry was subsequently held so as to enable the corporation to borrow

£160,000 to go on with the scheme, but on March 15th, 1899, the Lancashire City Council failing to ratify the action of the committee sent back the proceedings of the Rivers Committee. The effort was stated to be no better now than it was in 1896. After hearing evidence on both sides Mr. Yates, in giving the decision of the magistrates, said that they were convinced that the corporation was seriously alive to the necessity of doing something to purify the vast volume of sewage from a population of 600,000 people, and a rate of £10 per day for each of the five days for which the summons were taken out was indicated with £50 costs. No doubt there are and have been many difficulties in the way of the disposing of the sewage of a city like Manchester, still we cannot believe that they are unsurmountable.

LONDON SCHOOL NURSES SOCIETY

THE first annual meeting of this society will be held at the offices of the London School Board, Victoria Embankment, on June 15th, when the Councils of Aberdeen will take the chair, and will be supported by Lord Reay, the Hon. E. Lytton Stanley, Mr. Bradwell Carter, and Miss Amy Hughes. The London School Nurses Society was formed with the object of supplying visiting nurses to elementary schools in poor districts and already three nurses visit some of the poorest schools and attend to the small ill of the scholars—such as sore heels and inflamed eyes—while waiting for more serious conditions that would require treatment at the hands of the medical man. Each nurse is able to visit four schools in one day and see about 100 children, who are sent to her one by one by the teachers. As is pointed out by the secretary it will probably be difficult to impress on the public the importance of the work to be done or the necessity for these nurses, but it must be remembered that the sore heel soon becomes poisoned if left to London dirt, and that inflamed eyes often lose all power of seeing simply through neglect. There is no more sure way of securing the health of the people than to arrest small ill at the beginning and a nurse can often see at a glance whether a child should be sent to a medical man. The cost of each school nurse is about £50 a year as her full time is not needed. The committee urgently appeal for subscription or donations, amounting at least to £300 a year, to enable them to carry on the work in Hoxton, Tower Hamlets, and Bowditch, and to start three more nurses where they are most needed. All subscriptions should be sent to the Hon. Treasurer at 39, Harley street, London, W.

THE SALE OF FOOD AND DRUGS ACTS IN PRACTICE.

IT will be conceded that the experience gained from the collection and analysis of 14,000 samples secured under the Sale of Food and Drugs Act should afford some practical lessons. Such an experience is recorded by Dr. Kaye, the medical officer of health of the West Riding County Council, Wakefield, in a paper which he read before the Yorkshire Branch of the Sanitary Inspectors' Association some weeks ago and which has since reached us in the form of a little pamphlet. The perusal of this paper is especially interesting at this time, when we may shortly expect a new Act Dr. Kaye shows, as we have often shown, that the surest way to reduce the prevalence of fraudulent practices of adulteration is to take greater numbers of samples for analysis. He further shows that, in particular, the adulteration of milk has diminished in accordance with an increased number of samples taken and Drugs Act should be directed to how far the Food preservatives in food. The paper was primarily designed for

MR. CHAPLIN'S DIFFICULTIES

LAST year's blundering on the subject of vaccination pursues the Government like a Nemesis. In last week's debate in the House of Commons on the Local Government Board Vote they were despatched by their friends and badgered by their foes, and though when the division came the usual party discipline prevailed Mr. Chaplin had not a single Ministerial supporter all through the discussion. His opponents took credit to themselves for having forced in the matter of the appointment of vaccination officers the Government to make Mr. Chaplin yield further or at least did their best to emphasize the difficulties of the situation. The improvement in the returns of infantile vaccination in various parts of the country is not to the liking of the Anti Vaccination League and they are anxious to find material for another popular agitation. It only they could get the public, or martyrs their object would be gained, and, remembering the imprisonment of the Highley Guardians many years ago, they appear to think that the Leicester Guardians might now be similarly dealt with and with similar results. True,

THE METROPOLITAN HOSPITAL SUNDAY FUND
A MAGNIFICENT DONATION
The Metropolitan Hospital Sunday Fund for 1899 has made a promising start owing to the generosity of Mr. George Hennig of Hamilton place, who has given the largest individual donation of £10,000, the fund Mr. J. Lane Denham, whose name is well known in connection with the Mazawattee Tea Company, has given 1000 guineas, and several other considerable donations have also been received.

OF this inquiry
The word which we have printed in italics should have been dealers by publishing their names on a sort of black list, and proceeded to pillory, a la Labouchere, the offending 1850 instituted an inquiry into the various articles of diet the late Dr. Thomas Wakley, Editor of THE LANCET, who in the way of protecting the public health from adulterated foods, &c., seems to have been due to the action of the following sentence, 'The first real progress in historical review of the ancient practice of adulteration serves as a suitable preface and in this occurs for want of compliance with the proper procedure. A buy and what not to buy, and the steps to be taken through, the information and instruction of inspectors as to how to purchase samples, what ought should be provided, what to

the refusal of the Leicester Guardians to appoint a vaccination officer seems less likely to lend itself to their purpose than did the refusal of the Keighley Guardians to prosecute defaulters, but in their estimation any grievance is better than none and so Mr. Chaplin is asked if he will imprison the Leicester Guardians if they will not find the money to pay a vaccination officer. It is certainly unfortunate that he seems here to have rather played into the hands of his enemies by giving them the opportunity of alleging that the principles of local government are being infringed when guardians have to pay the salary of officers who are in a sense independent of them. But that, again, is only part of the doings of Nemesis. Last year the Government would not take the trouble or responsibility of introducing a really good Bill and now they are paying the penalty, for Mr. Chaplin cannot afford to let the Leicester difficulty remain undealt with and still less can he afford to deal with it by yielding. Looking to their unfulfilled promises in the matter of revaccination, it is not surprising that the Government receive little sympathy in their difficulties either from the medical profession or from their own supporters.

DANGEROUS PAVEMENTS

WHERE the local authorities do not undertake or contract for the cleansing of footways and pavements adjoining any premises they may make by laws imposing this duty on the occupier of any such premises. This is the substance of an important provision in the Public Health Act which may place occupiers under some responsibilities which have not perhaps been considered. The butcher or the greengrocer, probably gives little heed to the responsibility which may arise when by negligence he allows the pavement immediately opposite his shop to become dangerous through some person stepping on a piece of fat, orange peel, or banana skin. It frequently happens that the area in front of a busy butcher's shop becomes slippery, especially in the hot weather, and in the event of an accident, which is not at all improbable, the butcher or greengrocer might be liable for very substantial damages, as indeed he ought to be. Yet there is ocular evidence on the pavement day by day opposite most greengrocers' and butchers' shops in the metropolis of negligence in this matter which might lead to serious results. In many cases we have seen the pavements thus rendered quite dangerous to the unwary passer-by. The provisions of the Public Health Act, in our opinion, should be very strictly enforced in such a case, and, further, the police should be empowered to arrest a person who is found guilty of throwing a slippery substance like orange peel on the pavement.

RED LIGHT AS A THERAPEUTIC AGENT.

IN our conscious superiority to our forefathers we have been used to look with contempt on their practice of treating cases of small pox by means of red light in the form of red blinds, curtains, and coverlets, but with our present knowledge of the chemical and physical action of the different rays of the spectrum and the influence of light and darkness on life animals, highest and lowest manifestations we may have felt a suspicion that, whatever the theory of the mediæval physicians, their practice may have had a scientific basis. In the last number of the *Zeitschrift für Krankheitspflege* we find that it has been tried, and, apparently, with remarkable results, in the treatment of measles. A child, eight years of age, having sickened with an attack of measles of more than usual severity, was on the second day brought under the influence of the rays of least refrangibility, the windows being fitted with red blinds and a photographer's lamp with an orange-yellow globe being used for artificial light. In three hours the rash had disappeared, the fever had subsided, and the child was

playing cheerfully, complaining only of want of light. The blinds were consequently removed, when three hours later the medical man was summoned to find that the eruption and fever had returned and the child was weak and prostrate. The red light having been resumed the rash disappeared in little over two hours, as did the fever, this time permanently. In two more days the cough had ceased and the child was well in every respect. The brother and sister and a fourth patient infected from the first case were treated in the same way and with like success. In the great epidemic of small pox in 1871-72 some cases were reported as having been kept in dark rooms with great benefit, especially as regards the pustulation and pitting. Clearly what virtue there may be in this method lies in the exclusion of actinic rays and the substitution of red or orange light for total darkness has obvious advantages as in the case of photographic manipulations.

"THE SANITARY CONDITION OF ST PANCRAS"

IN our issue of June 3rd we commented upon a report of a special committee of the Health Department organisation of the Vestry of St Pancras. We had not, however, before us the minutes of evidence upon which this report was founded. The report referred to the "disorganisation" or "demoralisation" of the health department and in view of the importance of the matter we have applied to the Vestry of St Pancras for a copy of the minutes of evidence, asking the vestry either to send us a copy or to be good enough to inform us as to where we can procure a copy. As soon as we have the evidence before us we shall return to the matter again.

We have received from Mr. W. Hugh Spottiswoode a copy of a memoir of the late William Spottiswoode, which from the fact that the centenary of the Royal Institution was celebrated this week is of great interest. It contains an address "On the Old and New Laboratories," delivered before the Institution by Mr. Spottiswoode, who was closely associated with its administrative affairs. He was also President of the Royal Society from 1879 to 1883 and had devoted much of his time to physical research. Mr. Hugh Spottiswoode has recently presented to the Institution the collection of physical apparatus which belonged to his father, an excellent "Woodbury gravure" of whom forms the frontispiece to the memoir.

MR. ROBERT WALLACE, M.P. for East Edinburgh, while speaking in the House of Commons on Monday night last was suddenly seized with cerebral hemorrhage. When he was unable to continue his speech and was discovered to be suffering Sir George Pilkington and Sir William Priestley came to his aid. Mr. John Burns accomplished no mean athletic feat by lifting Mr. Wallace in his arms and carrying him out of the House. Later he was removed to Westminster Hospital, where he died early on Tuesday morning. The tragedy elicited the fact that the House of Commons is entirely without ambulance accommodation—a state of things which calls for attention. The Duke of Marlborough has given, in memory of his grandmother, Frances Ann, Duchess of Marlborough, a donation of £500 towards the cost of providing the new operating theatre of the Radcliffe Infirmary, Oxford, with appliances and equipment of the latest completeness. The operating theatre has been erected by funds supplied by Mr. J. H. Mason, of Eynsham Hall, Oxford, and by a subscription raised some years ago in memory of the present Duke's grandfather.

DR. BEATTIE CROZIER, the author of "Civilisation and Progress" and "A History of Intellectual Development," is

ROYAL COLLEGE OF SURGEONS OF ENGLAND

some 370 horses) included two camels, a kangaroo, and an emu, the last named, it may be mentioned in passing, showed a great partiality for milk. We believe that special arrangements were made to keep the stable scrupulously clean and the evidence of both sight and smell showed that these arrangements were well carried out. The arrangements for accidents which might happen either to the performers or the general public included a hospital and 20 men of the Royal Army Medical Corps stationed at various points in the building ready in case of emergency. The St John Ambulance Brigade was also represented. We are glad to be able to state that the candidates this year have been of a purely minor character.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

On Thursday, July 6th, the election of members of Council will take place. Usually at least three vacancies occur, but this year, as we mentioned in THE LANCET of May 13th, p. 1309, in consequence of the term of office of Sir William Mac Cormac, Bart., K.C.V.O., coming to an end during his Presidency, he will continue to be a member of the Council for one year longer, and therefore at this election there will be only two vacancies, for no vacancy through death has occurred.

The following list of the 24 members of the Council gives the date at which each member retires—

Retire in 1905 Mr H G Howse, Guy's Hospital (first elected 1880), Mr Henry Morris, Middlesex Hospital, and Mr John Langton, St Bartholomew's Hospital (first elected 1880).

Retire in 1906 Mr Thomas Bryant, Guy's Hospital (first elected 1880), Mr Edmund Owen, St Mary's Hospital, and Mr Rickman J Godlee, University College Hospital.

Retire in 1907 Mr A. Whistler, St Bartholomew's Hospital (first elected 1887), Mr H T Bustin, St Bartholomew's Hospital, and Mr R Treves, London Hospital.

Retire in 1908 Mr Reginald Harrison (first elected 1865), Mr Howard Marsh, Junior Vice-President, St Bartholomew's Hospital (first elected 1892), and Mr J Hardie, Royal Infirmary, Manchester.

Retire in 1909 Mr N O Macnamara, Westminster Hospital, Mr A W Mayo Hobson, Leeds General Infirmary, and Mr W Watson Osborne, King's College Hospital.

Retire in 1910 Sir William Mac Cormac, Bart., K.C.V.O., President, St Thomas's Hospital (first elected 1883), St Thomas Smith, Bart., St Bartholomew's Hospital, Mr J Tweedy, University College Hospital, and Mr Alfred Cooper, Royal Infirmary, in 1899.

Mr T R Jessop, Leeds General Infirmary, and Mr J Ward Cousins, Royal Portsmouth Hospital, in these names shows that at present St Bartholomew's Hospital has four representatives, Guy's Hospital has three representatives, University College Hospital has two representatives, and each of the following hospitals has one representative, St George's, King's College, London, Middlesex, St Mary's, St Thomas's, and Westminster. There are thus 17 members of the Council attached to the London medical schools, there are two members of the Council who are attached to special London hospitals, and five are attached to provincial hospitals. Leeds General Infirmary has two, and Bristol Royal Infirmary, Manchester Royal Infirmary, and the Royal Portsmouth Hospital have each one.

VITAL STATISTICS

IN 33 of the largest English towns 7265 births and 3872 deaths were registered during the week ending June 3rd. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 17.7 to 16.0 per

THE ROYAL MILITARY TOWNSHIP

Lord ROSEBURY has promised to be present on Monday Day, Saturday, July 29th, at the Royal Medical Benevolent

made by H.R.H. Princess Christian

June 3rd at Grosvenor House, W., the presentations being

The annual distribution of diplomas awarded by the

presenting badges to members on the occasion

of the annual meeting of the Royal British

of the University of Toronto, the Governor-General of

There is every reason to believe that at the close of the Royal Military Tournament which will have taken place by the time we have gone to press the receipts will be found to be even greater than last year which was a "record" one. Many of the seats, we understand, have been paid for by the charitable who wished to help the military charities but were unused, hence the seats which were noticed to be unoccupied as a feature of the Tournament we have endeavored to help the authorities to turn an unsuitable building into a sanitary success. Under the able direction of the medical officers who have been in charge of the Tournament the Royal Agricultural Hall has been improved year by year and at the present time the hygienic conditions of the building are as perfect as it is possible to make them considering that the Hall at Kingston was never intended to be put to the threefold use at the same time of a theatre, a military barracks, and stables. As we have said the entertainment is an assured success and it is difficult to understand why the authorities do not remove the Tournament to a more suitable building or even erect either a permanent or temporary building of their own. We have urged this course on several occasions and we feel certain that the press generally would support such a departure. An amusing illustration of the difficulties with which the medical officers have to contend was shown by the action of some of the sailors engaged. Both sailors and soldiers, as a rule, do not love too much fresh air in their sleeping quarters and they frequently prefer the comfort of a small space, as is easily understood that it is necessary to have as many windows open as possible. This, however, many of the sailors resented and it occasionally happened that a medical officer consequent of his responsibility with regard to the health of those under his charge and making a tour of the sleeping quarters in the small hours of the morning found that a sailor, had climbed to the roof and closed a window with excuse on being caught being usually, "Oh, sir, I felt such a draught." In a properly constructed building such incidents could not happen in spite of the difficulties with which they have to contend. Medical officers do their work excellently and both Major Crooke Lawless of the Coldstream Guards, are to be congratulated on the perfection of the arrangements this year. While, however, congratulating the medical officers we must not forget Veterinary Major R. Howe, A.V.D., who had charge of the animals in the building which besides

1000, rose again last week to 17.7. In London the rate was 17.0 per 1000, while it averaged 18.2 in the 32 provincial towns. The lowest rates in these towns were 8.5 in Brighton, 10.2 in West Ham, 11.5 in Cardiff, and 13.4 in Norwich, the highest rates were 22.8 in Preston, 22.9 in Wolverhampton, 24.3 in Liverpool, and 26.5 in Manchester. The 3872 deaths included 386 which were referred to the principal zymotic diseases, against 355 and 351 in the two preceding weeks, of these 142 resulted from measles, 80 from whooping cough, 69 from diphtheria, 45 from diarrhoea, 27 from scarlet fever, and 23 from "fever" (principally enteric). The lowest death rates from these diseases were recorded in Brighton, Croydon, and Cardiff, and the highest rates in Leicester, Bolton, Burnley, and Manchester. The greatest mortality from measles occurred in Nottingham, Liverpool, Bolton, Manchester, Salford, and Burnley, from scarlet fever in Bolton and Burnley, from whooping-cough in Oldham and Burnley, and from "fever" in Huddersfield. The 69 deaths from diphtheria included 24 in London, nine in Sheffield, eight in Leicester, four in Liverpool, and three each in West Ham, Swansea, Manchester, and Leeds. No fatal case of small-pox was registered during the week under notice either in London or in any other of the 33 large towns, and only one small-pox patient was under treatment in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2212, against 2161 and 2201 on the two preceding Saturdays, 260 new cases were admitted during the week, against 259, 211, and 229 in the three preceding weeks. Influenza was certified as the primary cause of 24 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had been 257 and 256 in the two preceding weeks, further fell to 240 last week and were 33 below the corrected average. The causes of 45, or 1.2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bradford, Leeds, Newcastle upon-Tyne, and in 14 other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Nottingham, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19.0 and 16.9 per 1000 in the two preceding weeks, rose again to 19.9 during the week ending June 3rd, and exceeded by 2.2 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15.5 in Leith and 16.9 in Paisley and in Perth to 20.8 in Aberdeen and 20.9 in Edinburgh. The 607 deaths in these towns included 17 which were referred to diarrhoea, 16 to measles, 16 to whooping-cough, 11 to scarlet fever, five to diphtheria, and three to "fever." In all, 68 deaths resulted from these principal zymotic diseases, against 60 and 62 in the two preceding weeks. These 68 deaths were equal to an annual rate of 2.2 per 1000, which was 0.4 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had declined from 27 to 11 in the three preceding weeks, rose again to 16 last week, of which 12 occurred in Glasgow and three in Edinburgh. The 16 deaths referred to whooping cough were within one of the number recorded in the preceding week, and included seven in Glasgow, six in Edinburgh, and three in Leith. The fatal cases of scarlet fever, which had been eight and three in the two preceding weeks, rose again to 11 last week, of which six occurred in Glasgow, three in Paisley, and two in Edinburgh. The deaths from diphtheria, which had declined from six to one in the three preceding weeks, rose again to five last week, and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 103 and 80 in the two preceding weeks, rose again to 108 last week, but were 25 below the number in the corresponding period of last year. The causes of 41, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 26.8 and 26.5 per 1000 in the two preceding weeks, further declined to 22.1 during the week ending June 3rd. During the past four

weeks the death rate in the city has averaged 25.5 per 1000, the rate during the same period being 18.4 in London and 17.9 in Edinburgh. The 148 deaths registered in Dublin during the week under notice showed a decline of 30 from the number in the preceding week, and included five which were referred to the principal zymotic diseases; against seven in each of the two preceding weeks, of these two resulted from whooping cough, one from measles, one from scarlet fever, and one from diarrhoea, but not one either from small-pox, diphtheria, or "fever." These five deaths were equal to a rate of 0.7 per 1000, the zymotic death rate during the same period being 1.7 in London and 2.3 in Edinburgh. The fatal cases of whooping cough, which had been three and one in the two preceding weeks, rose again to two last week. The mortality from measles corresponded with that recorded in the preceding week. The 148 deaths in Dublin last week included 24 of infants under one year of age and 34 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons showed a decline from those recorded in recent weeks. Six inquest cases and nine deaths from violence were registered, and 56, or more than a third, of the deaths occurred in public institutions. The causes of seven, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

STAFF SURGEON R. E. BIDDULPH is appointed to the *Duke of Wellington*. Staff Surgeon Herbert E. Marsh of the *Prince George* has retired in consequence of ill health. Surgeons—A. Gaskell to the *Find*, R. L. Price and E. S. Tuck to the Hong Kong Hospital, T. O. Meikle to the *Lanet*, and H. S. Burniston to the *Esik*.

ROYAL ARMY MEDICAL CORPS

Major O. H. Burtbaell joins at Woolwich and Major E. Eckersley is ordered to London for duty. Colonel W. F. Stevenson is granted a three years' extension of his appointment as Professor of Clinical and Military Surgery at the Royal Army Medical School, Netley.

YEOMANRY CAVALRY

Suffolk (the Duke of York's Own Loyal Suffolk Hussars). Surgeon Captain H. O. Martin resigns his commission, Alfred Cooper, late Surgeon and Honorary Surgeon Major, 14th Middlesex Volunteer Rifle Corps, to be Surgeon Lieutenant.

VOLUNTEER CORPS

Artillery. 1st Cornwall (Duke of Cornwall's) (Western Division Royal Artillery). Surgeon Lieutenant R. T. Cann resigns his commission. Surgeon-Lieutenant C. O. Bullmore, from the 1st Volunteer Battalion the Duke of Cornwall's Light Infantry, to be Surgeon Captain. *Royal Engineers*. 1st Northamptonshire. Surgeon Captain W. Easby resigns his commission. *Rifle*. 2nd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment). Henry Mitchell, late Surgeon Major, Royal Horse Guards, to be Major. 2nd Volunteer Battalion the Royal Welsh Fusiliers. William Owen Evans to be Surgeon Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry. George Stephen to be Surgeon Lieutenant. 2nd Volunteer Battalion the East Surrey Regiment. Surgeon-Major W. Gandy to be Surgeon Lieutenant-Colonel.

INOCULATION FOR ENTERIC FEVER

In our issue of May 27th we announced that the War Office has decided that soldiers proceeding to military stations abroad where enteric fever is prevalent shall be given the opportunity, should they care to avail themselves of it, of inoculation against that disease. The operation is entirely a voluntary matter as far as the soldiers are concerned. Professor Wright of Netley, as the outcome of experimental investigations into the subject, considers that such inoculations exercise a protective influence against the disease and, as our readers are aware, when in India as a member of the Plague Commission he addressed some remarks, with the permission of the military authorities there, to the men of some British regiments serving in India. Considering the scourge which enteric fever is to the young soldiers of our army serving in hot climates and the susceptibility of new comers to be attacked by it Professor

'cause endless complications. Whether with a majority of the people in its favour compulsion can be ethically maintained is a question which is open to argument, but with a majority on the other side it is hopeless.

The question is—What is the remedy? and at present, "force is no remedy." In a matter of this kind Englishmen abhor compulsion as nature abhors a vacuum. The people may be educated into appreciating the benefits of vaccination but they will not be driven to it. The case for vaccination should be brought to the notice of every parent on the registration of a birth. Vaccination should be free and easily obtainable, with present conditions as to lymph, and operation, and the duty of ascertaining whether vaccination is desired by the public vaccinator might be entrusted to the vaccination officer. If this were done the four months' limit might be done away with and the allowance of vaccination of children by parents would be practically voluntary. Indirect compulsion for the protection of private or public interests would still continue and, like indirect taxation, would be little felt.

I am, Sirs, yours faithfully,

J B PIKE

Loughborough, May 30th, 1899

"PLAGUE IN BOMBAY"

To the Editors of THE LANCET

SIRS,—IN THE LANCET of April 22nd (p. 1115) there appears under the heading of "Plague in Bombay" a review of the report of the Austrian Plague Commission. Whilst I am deeply sensible to the gratitude expressed by the commission for the help I gave them I cannot in justice to myself and to the institution I control allow some statements which appear therein to go unchallenged. But inasmuch as the writer—the late lamented Dr H F Müller—is no longer alive, I shall refrain from all personal allusions and confine myself to facts in dealing with his statements. Dr Müller says "It was not customary at this hospital to use percussion or the stethoscope, and as we did so we seemed to incur the charge of unnecessary cruelty to the patients, we could not therefore rely on the nursing staff for assistance in this matter." This statement, you will allow me to state, is quite erroneous, to use no harsher term. The patients never objected to percussion or auscultation as practised by us, but they, their friends, and the nurses were not used to the somewhat violent and anything but tender or gentle ways and modes of practice of continental physicians. Dr Müller's manner and method of examination were disliked by all because of their roughness and because he would in all cases and without the least regard to the feelings of the patients or their friends assist in thoroughly examining them even when moribund or semi moribund. It is true he was carried away by the excess of zeal in the study of plague and did it with the best intentions, but to him a plague patient was not a *vian* but an *interesting case* for study and hence it was that there were frequent squabbles between him and the nurses and I had had often to intervene in order to pour oil on the troubled waters and thus smooth away difficulties. Unfortunately, Dr Müller had a quick, hasty, and irritable temper and used to take offence when none was meant and thus was intensified by his want of proper knowledge of English. My position was therefore very delicate, as on the one hand I had to give him all the assistance I could and on the other to see that the patients' friends were not dissatisfied or grumbling about his ways. It was indeed a happy relief to me when all these disputes ceased and Dr Müller had finished his examinations.

As regards the examination of urine, &c, Dr Müller had daily examinations of several specimens and even after his return to Vienna I had forwarded to him several samples of urine properly preserved according to his directions.

All the cause of soreness on his part was attributed partly to the above facts and partly to his idea that although we had studied over 1000 cases of plague before he came on the scene in Bombay we knew nothing about it. You were kind enough to review my report on plague in 1898 and as I had published plague work *before* his report was out he felt somewhat disappointed and claimed priority in certain matters which I would not admit and hence all this bitterness.

As regards the defects in the post mortem room, &c, you will no doubt admit, that to gentlemen fresh from Vienna with laboratories and post-mortem rooms replete with all modern appliances our hastily improvised arrangements must have appeared crude, but such as they were they were

placed at their entire disposal and that with all the difficulties that they mention they were able to do so much shows that they could not have been very serious. The Austrian Commissioners never realised our difficulties in dealing with the patients and their friends and their strong and deep-rooted prejudice towards hospitals and to anything like interference with their dead. It was at times as much as my personal safety was worth to get them a body for post-mortem examination; and there were frequent threats of assault on me and my staff and on the post mortem room. And having assisted them in the way I did, it was scarcely generous of the commission to flout before the professional world some small inconveniences they had to put up with. This is all that I need say on the subject. Our difficulties you have already realised and some of them I have already described in my report. You may make what use you like of this letter and publish as much of it as you consider proper. I have been compelled to enter at length into this subject as otherwise you would not have been able to fully gauge the meaning of a short reply.

I am, Sirs, yours faithfully,

A H OHOKSY,

Khan Bahadur Chevalier of the Crown of Italy;

Medical Officer in charge, Arthur-road

Hospital Bombay

May 20th, 1899.

"THE PATHOLOGY OF THE PERICARDIUM"

To the Editors of THE LANCET

SIRS,—The point raised by your correspondents Dr Harry Campbell and Mr Barnard as to the mode of breathing in runners is one of great importance, especially to those who are interested in the subject of respiratory exercises. Dr Campbell maintains that expirations during running are necessarily incomplete, while Mr Barnard says that "in a well trained cross country runner whose heart and respiratory pump are efficient for the exercise he undertakes inspirations are profound and expirations complete." I am disposed to differ from Mr Barnard in this statement for the following reasons. In running the chest is held in an inspiratory phase—that is to say, the dorsal spine is kept extended and the shoulders are braced back, this position gives the best *point d'appui* for swinging the arms freely to and fro. All long distance runners whom I know make use of this position and I have frequently observed it while running with harriers.

For a long time past I have been making observations with the spirometer on singers and speakers and also on runners, and I have found that when the "expirations are complete," as Mr Barnard says they should be, the whole position is the reverse of that described above. The dorsal spine is flexed—that is, it is in an expiratory position—and the shoulders and arms are brought well forward so as to decrease the antero posterior diameter of the chest as much as possible and the chest is collapsed. I have never yet seen this position assumed during running.

I am, Sirs, yours faithfully,

Harley-street W, June 6th 1899.

GEORGE OATHEART.

LECTURESHIPS ON "TRADE DISEASES."

To the Editors of THE LANCET

SIRS,—We are having schools of instruction in "tropical diseases" established in London and Liverpool, while lectureships on that subject have been instituted in Edinburgh and elsewhere. All this is very satisfactory. As a maritime and colonising people and as the holders of tropical possessions it is essential that our medical men should have every facility for acquiring a practical knowledge of the maladies prevalent in hot countries. But while congratulating ourselves on this important step which has so direct a bearing on our interests abroad I think it would be well to give some attention also to a matter which lies nearer home. I refer to the providing of instruction in regard to diseases arising from, or aggravated by, the industrial pursuits of our British people. We are a maritime people and a colonising power but we are also, and first of all, a manufacturing people. Our position in the world—our wealth and our power—essentially depend on our skill and capacity as manufacturers. Our possessions abroad afford markets for our goods, and our ships convey them thither, but at the root of all lies the making of these goods.

ago to change my name (omission of two superfluous Christian names) by deed poll registered in the High Court of Justice. The officials of the Royal College of Surgeons and the Apothecaries' Company at once complied with my request to make the correction in their official list, but the General Council of Medical Education and Registration refused to make the necessary alteration till I paid them a small fee, which I did under protest. This, no doubt, explains the omission you refer to in the case of Sir George F. Ross, your faithfully,
L. H. O'NEILL, M.D. F.R.S. Ed. and L.S.A.
June 10, 1899.
Birmingham.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT BERLIN
(FROM OUR BERLIN CORRESPONDENT)
(Concluded from p. 1571)
THIRD DAY
Curtailment of Tuberculosis

PROFESSOR CURSCHMANN (Leipsig) said that cases might be regarded as cured when the tuberculous infiltration had no tendency to exacerbation, when there was no extension of the morbid process to other parts of the lungs, and when the general state of the patient continued to be good. These conditions were not infrequently fulfilled, and a still greater number of patients were relatively cured, the local process continuing, but the patients nevertheless feeling quite well and being able to work. No reliable statistics could be given as to the percentage of cases cured. The modern dietetic and hygienic treatment had given the best results. No real specific remedy had yet been discovered. The cases where tuberculosis was still in the first stage had the best chances of being cured and early diagnosis was thus very important. The so-called "latent" forms must be specially kept in view. The influence of climatic conditions was not so great as had been believed and "immune zones" did not exist. Persons whose social circumstances were propitious and those who were no longer young had the best prospects of recovery. Predisposition to tuberculosis might be hereditary.

Professor BAZZANI stated that an unwarranted pessimism had succeeded the enthusiasm with which Professor Koch's discovery was at first received. It was nevertheless undeniable that tuberculosis had a specific action and that it enabled a diagnosis to be made of doubtful cases, but in advanced cases the tuberculin test failed, because the organism was already saturated with tuberculin. The majority of medical men were now opposed to the use of the tuberculin test, as they were afraid of accidents which might, however, be easily avoided. Tuberculin was, moreover, a specific remedy for tuberculous, acting exclusively on the tuberculous process and being without any influence on the complications. Uncomplicated tuberculous in the first stages might sometimes be cured by the administration of tuberculin, and cases in a more advanced stage, where tuberculous was combined with other pathological alterations, might be improved. A good deal of experimental research for the selection of cases fit for the tuberculin treatment. In sanatoriums tuberculin ought to be used together with the other methods of treatment.

Sir HERBART WEBER (London) was explicit in stating that it was useless for a patient merely to reside at a health resort without being at the same time under medical supervision. For the majority of patients, especially for those of the poorer classes, the treatment, in a sanatorium, was preferable. Speaking of the selection of a health resort he said that patients in whom the progress of the tuberculous was slow ought to seek a warm climate, if tuberculous was combined with diabetes places with a dry and warm climate were preferable. Cases with severe catarrh must be sent to sheltered places, patients whose constitution was relatively strong could benefit from residence in high altitudes or from sea voyages. The houses occupied by the patients should stand on a dry site and should be exposed to the sun, they must also be sheltered from cold winds and draft. Patients at health resorts must on no account forget the hygienic games or social entertainments, and for this reason among

And therefore the health and well being of those engaged in industrial pursuits is to us as a nation a matter of prime importance. So far as I am aware there is no lectureship or special course of instruction given on "trade diseases" in this country. I am aware that this is provisionally under the heading of "Hygiene" and that it is dealt with as a part of "public health," and it may be argued that this is provisionally enough. "I do not think so. As well may it be contended that 'tropical diseases' fall under the heading of 'Practice of Medicine' and that therefore special courses on that subject are unnecessary. My proposal is that special lectureships on 'trade diseases' should be instituted at the medical schools. In our large manufacturing towns and that these lectures should be illustrated and supplemented by visits to factories and public works. These visits would afford valuable object lessons to the young students of Asculapian, not only concerning their knowledge of the conditions of the labouring classes and giving them some idea of the wonderful skill and energy which have placed us where we are as a nation. I must cut this letter short as I have already encroached too much on your space. Hoping that the subject may be taken up,
I am, Sirs, yours faithfully,
JAMES W. ALLEN, M.B. Glasg.,
Dispensary Physician, Glasgow
Royal Infirmary.
Glasgow, June 5th, 1899.

THE INCUBATION PERIOD OF THE CHICKEN POX
To the Editors of THE LANCET
Sirs—I was recently asked to attend some children who were "broken out all over." On examination I found that they were all suffering from varicella as was a seven day old infant, who had a good crop of typical chicken pox vesicles. The case of this infant seems to me to be worth recording as an instance of varicella where the incubation period could not possibly have been more than seven days from 10 days to a fortnight is the period given by most authorities—I am, Sirs, yours faithfully,
C. J. BISHAM, M.D. R.U.I.
Gatcombe-road, Tufnell-park London, N. June 5th, 1899.

THE VICE-PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND
To the Editors of THE LANCET
Sirs,—Inasmuch as there was no change in the office of President or Vice President this June election which took place to-day, I desire to inform the Fellows of the College that last year when I expressed to the electors my determination to offer myself for the office of Vice President I felt that my long service to the School and College as senior demonstrator, examiner, and councillor, and my seniority as a surgical teacher and as a hospital surgeon, might reasonably deserve recognition by the Fellows and that I might hope to be honoured with election to the office I then sought. Unhappily, personal and domestic circumstances prevented me from giving preference to the office I had hoped to be honoured with election to. I thought it best to refrain from presenting myself for the vice-chair until the next legitimate vacancy occurs in June, 1900. I desire, however, to assure the Fellows that under any circumstances I shall do so when that time arrives. With this intimation I trust that my friends and supporters among the Fellows will not be induced to pledge their votes to any other candidate for the next Vice-Presidency—I am, Sirs, yours faithfully,
L. H. O'NEILL, M.D. Dub., F.R.O.S. Ire.
Merrion-square, Dublin June 5th, 1899.

THE ACCURACY OF THE MEDICAL REGISTER
To the Editors of THE LANCET
Sirs,—Your annotation in THE LANCET of June 3rd (p. 1503) headed "Sir George Puckington, M.P., and the Medical Register," interests me. I had occasion some years ago to change my name (omission of two superfluous Christian names) by deed poll registered in the High Court of Justice. The officials of the Royal College of Surgeons and the Apothecaries' Company at once complied with my request to make the correction in their official list, but the General Council of Medical Education and Registration refused to make the necessary alteration till I paid them a small fee, which I did under protest. This, no doubt, explains the omission you refer to in the case of Sir George F. Ross, your faithfully,
L. H. O'NEILL, M.D. F.R.S. Ed. and L.S.A.
June 10, 1899.
Birmingham.

others they ought to be under the care of local physicians. In every climate pulmonary tuberculosis was curable at the onset and the multiplication of sanatoria was strongly to be recommended.

Treatment of Tuberculosis by Drugs

Professor KOBERT (Rostock) said that the physician could not do without the administration of drugs in advanced cases where hygienic treatment was no longer available. Sedatives, antipyretics, tonics, &c., must be prescribed according to the requirements of individual patients. In local tuberculosis of the bones, joints, and skin iodoform was very useful. Creasote was to be recommended in the later stages together with injections of camphorated oil. The results said to have been obtained with ichthyol, cinna-mic acid, and Peruvian balsam required further verification. — Dr VON SCHROTTER (Vienna) showed two patients who had been operated on for laryngeal tuberculosis 13 and nine years ago respectively and who were permanently cured. — Dr J G SINCLAIR COGHILL¹ (Ventnor) spoke of the hygienic and dietetic treatment followed in England and Dr DETTWEILER, physician to the Falkenstein Sanatorium, on the open air treatment. — Professor LANDERER read a paper on treatment by cinna-mic acid.

FOURTH DAY

The Congress on this day took into consideration the subject of sanatoria for the wage earning and the poorer classes. A great many delegates from the sick clubs and trade unions of Germany attended, and were received in terms of welcome by the Chairman, Dr Gaebel, President of the Imperial Insurance Office.

The Origin and Maintenance of Sanatoria

Professor VON LEIDEN stated that the first sanatorium for the poor was established in England as early as 1814. Now-a-days sanatoria existed in nearly every country of Europe and in America. In Germany the first endeavours to establish sanatoria were made in 1882, especially by the Verein für Innere Medizin. There were at present 31 sanatoria in Germany for the benefit of the working classes. — Herr MEYER (Berlin) then read a paper on sanatoria from the financial point of view. He argued that they ought to be supported by sick clubs, by employers' associations, and by the State.

Phthisis among the Working Classes

Dr R FRIEDEBERG, the delegate of the Berlin Industrial Sick Clubs, was of opinion that tuberculosis was peculiarly a disease of working people as every second member of the clubs died from this cause. The working classes appreciated the efforts of the Government and the charitable associations in combating the disease but they believed that matters would not improve until better social conditions prevailed. The medical officers to the sick clubs ought to be authorised to send phthisical patients to sanatoria in an early stage while a cure was still possible. The nature of the disease and the methods of preventing it ought to be explained to working people by medical men reading papers at club meetings and by pamphlets written in popular language, and the inspectors of factories ought also to have a watchful eye on their hygienic conditions.

Provision for the Families of Phthisical Subjects

Dr PANNWITZ said that systematic arrangements ought to be made for maintaining the families of phthisical workmen. Working men were apt to come to the sanatoria too late and to take their discharge too soon because they were afraid of leaving their families in distress. A good deal of charitable work might be done by the Red Cross Association in relieving their families, and the future of those who had left sanatoria either cured or improved also invited attention. Whilst staying in the sanatoria the patients must be helped to find employment perhaps more suitable for their health. Dr Pannwitz recommended the establishment of farms where the patients after having left the sanatoria might stay for a certain time and be employed in agricultural work.

Dr RUFENACHT WALTERS (London) described the sanatoria in Great Britain, mentioning that in England the open air treatment had been in use a long time before Dr Brehmer established the first sanatorium in Germany.

Professor BAGINSKY advocated the establishment of special sanatoria for children.

Dr WEICKERS (Görbersdorf) said that he had inquired into the state of health of the patients after they had left the sanatorium. He had found that of those who had come for treatment in the beginning of the disease more than 95 per cent remained in good health for more than four years. Patients with very advanced tuberculosis were unsuitable for sanatorium treatment. It was an act of unwise sentimentality for a medical man to send such cases to sanatoria where they disturbed the other patients without deriving any benefit themselves. It had been ascertained by statistical research that the life of these patients was not prolonged by residence in a sanatorium. — Professor BROUARDEL (Paris) expressed approval of the opinions held by Dr Weickers.

Papers were also read before the Congress by Professor EWALD, on Sanatoria at the Seaside, by Dr HOBBS, on Sanatoria for the Middle Classes, by the Spanish delegate, Dr JOSE JUAN DOMINE, on the Spanish National Sanatorium in Porta-coeli, by Dr VAUGHAN on Sanatoria in England, and by Dr MOHARREM BEY (Cairo) on International Sanatoria. The Congress was closed on Saturday, May 27th, by the honorary president, the Duke of Ratibor. Professor BROUARDEL expressed the thanks of the foreign delegates to the committee.

The members of the Congress were shown over the sanatorium of the Red Cross Association at the Grabow See, near Berlin, and the sanatoria in Belzig and Blankenburg. The committee and the foreign delegates, including Sir Thomas Grainger Stewart and Sir Hermann Weber, were received by the Emperor and Empress at Potsdam.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

Captain Leumann's Report on Inoculation for Plague in Hubli — The Decline of Plague throughout India — Plague in Mauritius

THE town of Hubli has perhaps afforded the best test for the value of inoculation in plague and the report of Captain Leumann, I M S, is so exhaustive that we have in it one of the fullest records of plague administration and of the efficacy of inoculation. General sanitary measures were adopted and isolation of the sick with segregation of contacts and evacuation of infected dwellings were also carried out, but—and here is the difference—inoculation was given a full opportunity by the concessions which were granted to those who were twice inoculated. These people were allowed to remain in their homes and to carry on their occupations. The consequence of this policy was that the natives inundated the inoculation stations clamouring for the operation. They moreover saw that persons inoculated almost entirely escaped the disease while those not inoculated suffered severely. From May 11th to August 23rd 33,880 persons were inoculated (24,138 twice, 9742 once). In all 58,018 inoculations were performed in 15 weeks, or an average of over 550 a day. Captain Leumann has himself performed 22,000 inoculations and on one day performed over 1000 operations.

The statistics of mortality have all been published before. Suffice it to say that the actual plague deaths have averaged 85 per cent in favour of the inoculated. Over 95 per cent of the population of Hubli have now been inoculated. Captain Leumann nevertheless says "While paying the highest tribute to the value of Mr Haffkine's inoculation method which I claim here in Hubli to have been put to perhaps the severest test to which it has been subjected I am of opinion that individual protection is, on however great a scale conducted, of less importance to that of general protection by sanitation and hygiene (considering each method separately, that is to say) for it seems to be more radical if not more rational to eradicate a disease than to leave it to pursue its course and only to protect people against its ravages. But I see no reason whatever why the two methods should not be utilised together and as there appear to be various difficulties regarding the proper application of sanitary measures to allow inoculation its fullest scope." Amongst other observations recorded Captain Leumann says that the general health of inoculated persons seems to be improved as shown by the lower death rate from

¹ Dr Coghill's paper was published at length in THE LANCET of June 3rd. We regret to learn that Dr Coghill died shortly after his return to England. An obituary notice will be found on page 1588.

"other causes." He has found pustular eruptions not only cases noted was greatly aggravated, and in undoubted phthalic acid and of sweats. Two cases of long-standing epilepsy were supposed to have been cured Captain Leemann admits that owing to the great difficulties in carrying out sanitary measures incitation must of necessity come more prominently to the front. He still holds that early notification is the first and most essential factor in dealing with epidemics, but he knows that the natives of India will not notify and records the fact that not more than 20 per cent of plague cases in Hubli have ever been reported as such before death. He also holds that the removal of plague cases is equally important. The fact that neither of these objects can be accomplished in the face of native apathy or opposition would surely suggest that individual protection by inoculation was a much more important measure during a plague epidemic than any attempt at general sanitary administration. It is necessary to employ segregation and extermination as an alternative, however, otherwise there would not be sufficient inducement to the native to be inoculated. Great tact seems to have been shown in plague administration generally for at other places where similar opportunities have been offered for the display of administrative capacity report is full of most interesting detail and will be a useful guide to the authorities in the Bombay Presidency should plague continue in India after the present season. There were 1133 deaths from plague in India last week. In the Bombay Presidency there were 1057 of which Bombay city accounts for 323 deaths and Kanara city for 181. As the general mortality in Bombay city was more than 500 over the average the Government returns of plague apparently fall far short of the actual truth. There were only 119 deaths outside the Bombay Presidency. Madras Presidency reports 10 North Arcot, 32 Salem district five Mysore State 51, Kolar Goldfields 32, Mysore city 18. The Punjab returns nine and Bengal returns 74, Calcutta contributing 60 and Howrah 14. All other Bengal districts now return clean bills. Calcutta shows during the present month a marked decline of plague deaths. Commencing in January with four deaths there was an increase in February to 28 deaths. In March the outbreak seemed to suddenly take on violence and 426 deaths were recorded. During April there were 499 deaths, but for the first 16 days of May only 131 have been recorded—a very rapid and marked decline. The general death rate for the past week was 40 per 1000 per annum, against 34.3 the mean of the last five years. In the suburbs the death rate was 39.3 per 1000 per annum, against 40.7, the mean of the last five years. The general death rate of the combined area is equal to 39.5. The three cities of Kanachi, Bombay, and Calcutta all show great improvement in the number of plague deaths. The Government of Madras reports three fresh cases of plague on May 1st.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Corporation and the Housing of the Working Classes. *Resolution of the Housing of the Working Classes Bill.* *Local Government Board.* *Inspector recently held an inquiry at the municipal offices with reference to an application of the corporation to borrow a further sum of £50,000 for the demolition of insanitary property and £13,500 for the building of workmen dwellings.* Dr Hope stated that the property was almost always presented by persons in which sickness had been practically eradicated from every other town in England, figured in the districts included in the preliminary survey the insanitary districts it would be found that the rest of the city had a death rate of under 18 per 1000 whereas in the insanitary districts the death rate was 40.2 per 1000. In Lancashire districts the population was from 500 to 1000 to the acre. The sanitary arrangements were abominable, especially in cases of sickness, had weather, or the presence of gangs of roustabouts, when the common conveniences at the end of a court could not be used. The Parks Committee had endeavoured to dig up these places by discharging window boxes, but it was found that owing to the absence of sunlight and air plants would not grow amidst these hovels. The property was ruinous, saturated in the interior with organic filth from generations of inhabitants, and owing to age and neglect insanitary of the grossest character were common. The Inspector asked whether the corporation proposed to rebuild at the same time that they demolished, as the Local Government Board felt that more should be done in the direction of rehousing. The Board required that a scheme of demolition should not be undertaken without considering what was to become of the population. Mr Henderson, one of the city councillors, said that since 1884, when these demolitions began, the destruction of insanitary property had progressed rapidly but the provision for rehousing had not progressed at anything like the same rate. On that occasion for example, the corporation were applying for £50,000 to demolish property and only £13,500 to rebuild. In his opinion the figures ought to be reversed. Dr Hope said that he was in a position to prove that previous demolitions had not resulted in overcrowding sublet houses as stated. In 1894 there were upwards of 20,000 sublet houses on the register supervised by a staff of 11 inspectors, who had been subequently increased to 13. As a result of stringent and provisions the sublet houses had decreased to 17,000 while the cases of overcrowding were fewer.

Sir W. Mitchell Banks, M.D. and F.R.C.S. Eng. The honour of knighthood—conferred on Mr William Mitchell Banks upon the occasion of Her Majesty's birthday. He has given unqualified satisfaction to the profession in Liverpool. Sir William Mitchell Banks's career has been highly distinguished. He graduated M.D. at the Edinburgh University in 1864, obtaining the gold medal for his thesis on the Wollman bodies. He subsequently became demonstrator for two years prior to his removal to Liverpool. His ability as a skillful surgeon received early recognition and the profession in that city have since bestowed upon him every honour which it was in their power to give. His first appointment in Liverpool was that of pathologist to the old Royal Infirmary. He also filled the post of lecturer in anatomy in the Royal Infirmary School of Medicine, becoming the first professor of anatomy upon the abolition of that school to University College in 1881. Sir William Mitchell Banks was amongst the foremost of the founders of the college and others, was due the rebuilding of the Royal Infirmary which he is now the senior surgeon dates from the year 1877. He has been a member of the Council of the Royal College of Surgeons of England and for some time represented the Victoria University on the General Medical Council. He filled the office of President of the Liverpool Medical Institution in 1880-91. A few years since the profession in Liverpool presented him with his portrait painted in oils by the Honourable John Collier. He was recently honoured by his alma mater—the University of Edinburgh, with the honorary degree of LL.D. His urbanity and kindness of manner are everywhere recognized and safely affirmed that he does not possess an enemy.

Hospital Saturday Fund Ladies Street Collection. The ladies' annual street collection in aid of the Hospital Saturday Fund took place on June 3rd in summer weather upwards of 900 ladies wearing white badges with the inscription "Ladies Hospital Saturday Fund," devoted themselves to the collection. The committee of the fund have made a new departure by collecting on the day prior to the street collection in offices and business premises where the principal seldom come to the city on Saturdays. Last year's street collection realized £793 chiefly from the workshops the substantial sum of £3099 has already been received by the treasurer of the Hospital Saturday Fund. This aggregate illustrates the value of systematic contributions.

The Prevention of Tuberculosis in Scotland

A CONFERENCE with respect to the prevention and control of tuberculous diseases took place last week between the Public Health Committee of Aberdeen Town Council and a deputation from the Aberdeen, Kincardine, and Banff Branch of the British Medical Association. Among the representatives of the former were Dr John Robertson, convener, and Dr A T Gordon Beveridge, together with Dr Hay, medical officer of health of the city. The deputation from the British Medical Association consisted of Professor Kinlay (branch president), Professor Stephenson, Dr Scott Riddell, Dr A T Milne, and Dr Edmond. Dr Hay's memorandum, of which a summary lately appeared in THE LANCET, having been considered, the medical men present approved of a regular inspection of dairies, the application of the tuberculin test, and the employment of a veterinary surgeon as inspector. These steps would, in their opinion, render sterilisation of milk unnecessary. As to meat-supply, they were in favour of a municipal slaughterhouse. With regard to the proposed sanatorium (in the country) for phthisical patients they were strongly in favour of the idea being carried out either at the expense of the rates or by voluntary subscription. On the suggestion of the deputation it was agreed to hold a conference with the directors of the Aberdeen Dispensary, the managers of the Royal Infirmary, and the Aberdeen Parish Council, with a view to a practical scheme being framed.

Aberdeen Royal Infirmary

The month's house to house collection on behalf of this hospital, organised by the executive of the Hospital Saturday Committee in Aberdeen, has produced rather more than £500—a result which has disappointed expectations. The proposed demonstration on behalf of the hospitals in the city has been postponed to August 11th and 12th next so as to admit of the attendance of a detachment of the New York

perforated with Great B. into camp at Charleston Park, Aboyne, Aberdeen, the first summer university, on the evening of June 1st.

The Royal Victoria Hospital, Belfast

At a meeting of the Executive Committee held on May 31st the plans for the new Belfast Royal Victoria Hospital were presented and unanimously passed. These maturer plans have been most carefully worked out by the architect, Mr Herman (who designed the Birmingham Hospital), in conjunction with the hospital staff and the construction committee. They provide for about 300 beds in 19 wards, generally of 16 beds each, with the necessary accessory rooms, including a certain number of single wards, all of which are situated on one floor level, thereby avoiding both staircases and lifts, in addition to which there is the extern department consisting of a large waiting hall surrounded by a number of consulting and retiring rooms. Adjoining this is the pathological department, all on the same floor level. The principal entrance is near the centre of the site on the Grosvenor street side, past a porter's lodge, to an open courtyard, around which on three sides are arranged the administrative departments, a spacious entrance hall being in the centre. On one side provision is made for the medical and surgical resident staff; on the other are sitting rooms for the nursing staff with bed rooms above. On the south side is a wide corridor running the full length of the building, by which all accommodation for patients can be approached. A large lecture theatre and suitable accommodation for students are also provided. In addition to the facilities in administration secured by having all wards and rooms for patients on one floor level the arrangement is particularly adapted for simplifying the application of the plenum system of ventilation which the committee have decided to adopt. The materials to be employed for the exterior have been selected with a view to produce a pleasing effect of colour—grey sand faced red brick and terra cotta for the walls, green slates for the roofs, and lead on the small-domed ventilating turrets.

Drumbeg Dispensary District

Mr Munce has been elected medical officer of the Drumbeg Dispensary District of the Lisburn Union.

Salary of an Analyst

The guardians of Newtownards, county Down, are advertising for a trained nurse and an analyst, the salary in the former case being £40 per annum, while in the latter candidates are required to state what sum they expect for making an analysis of about 100 samples of medicine.

Portstewart Dispensary

I am glad to know that the Local Government Board have declined to give their sanction to the miserable salary of £60 per annum proposed to be paid by the Coleraine Guardians to the Portstewart Dispensary medical officer on the ground that it was inadequate remuneration for the duties to be discharged. By a majority the guardians have now agreed to pay £75.

The Artificial Stimulation of Glands by Raising their Temperature

At the meeting of the Society of Biology held on May 20th M Lépine recounted some experiments which he had performed. He had found in the case of a dog the abdomen of which he had opened that if the spleen were lifted out and placed in a capsule so that it could be surrounded by water at a temperature of from 40° to 50° C, the injection of a dose of typhoid fever toxin which proved fatal to another dog under ordinary conditions was easily resisted by the dog experimented upon. Hence he considered that this treatment of the spleen produced an increased quantity of antitoxin. At the same time he found that the blood of the splenic vein contained less sugar than that of the carotid artery. If the warming of the spleen was continued for two hours, the proportion of sugar remained the same. But if the pancreas was warmed in the same way for two hours and its nerves stimulated the

digitalis, and recommending the nitrites and nitro-glycerine as therapeutic agents—Professor Tadassohn demonstrated some interesting cases, such as lichen ruber planus confined to the scrotum and the mouth, an "acrodermatite continue pustuleuse," apparently innocent but of very doubtful prognosis, and an erythema induratum (Bazin) in a scrofulous subject. In lupus erythematosus he advises the exhibition of quinine in doses of from 20 to 60 grains a day for months or the external application of a mixture in equal parts of alcohol, ether, and spirit of peppermint.

ROME

(FROM OUR OWN CORRESPONDENT)

The Averting of Hail Storms

HAIL, the "horrida grando" of Virgil, the "dira grando" of Horace, has nowhere more than in Italy been felt as a scourge. In 10 minutes the bursting of a hail cloud may convert a whole district, smiling with the promise of an abundant harvest or vintage, into a scene of desolation, leaving behind it economic ruin, hygienic harm, misery—individual and social—seldom even palliated by the heavy insurance which has already anticipated much of the hard-earned gains of the husbandman. In London some 25 years ago a fog of almost unprecedented duration and density inflicted such damage, notably on a great cattle show held at Islington, that it was seriously proposed on future visitations of the kind to clear the air by artillery, even at the cost (as then estimated) of £10,000. The proposal, transferred to Italy and applied to her hail storms, has quite lately been energetically carried out—mainly on the lines recommended and practised in Styria by Signor Stiger. At Turin a member of Parliament largely interested in agriculture, Signor Ottavi, has shown that the mortar used in Styria, and still more the "Unger cannon," also in use there, may be constructed in any well appointed Italian foundry—so simple are they in construction and operation. The mortar, for example, with a charge of from 80 to 100 grammes of gunpowder, rammed in not very tightly and plugged at the mouth with a stopper of unseasoned wood, can when fired off in repeated volleys keep a hail cloud at bay and even break it up and disperse it. Throughout Italy, but more particularly in the more robust, wealthier, more enterprising north, one reads of experiments tried with the most gratifying results in this new method of dispersion of hail. Let me quote an instance just communicated to me. In various districts of Monferrato in the Alta Italia a violent thunder storm accompanied by hail was devastating a series of upland farms at Trino Vercellese, Oamino, Pontestura, and Quarti. The storm was signalled to the people of San Giorgio Monferrato as "terrible," so they lost no time in preparing to give it a "warm reception." They had quite a park of artillery prepared, the cannon, as described by Signor Ottavi, being in great force. On came the storm-cloud and then flashed the volleys in rapid succession, till after two hours' bombardment the cloud revealed to the eye witnesses a large rent through which the blue sky was visible. It thereafter drifted away, leaving the "colles apertos," of which, according to Virgil, "Bacchus" is so enamoured, in full possession of all their menaced riches and smiling at the destruction they had escaped. Not a hailstone fell, but from the ragged edges of the retreating cloud there dropped a gentle and not unwelcome dew, hardly amounting to rain. The vine dressers, turned artillerymen for the nonce, find the practice more amusing and less costly than insurance. Of the two "charges" they prefer that of the "Unger cannon."

Three Deaths from Reckless Prescribing and Dispensing

I have had too frequent occasion to record the fatal results of the scandalously loose practice of prescribing orally and of dispensing without written instructions still prevalent in Italy and still jeopardising the lives not only of Italians themselves but of the stranger within their gates. The criminal court of Tortona, a considerable town between Alessandria and Genoa, supplies the latest and not the least sensational instance in point. Dr Giacomo Pezzotta, a medical practitioner, and Signor Francesco Beltrami, pharmaceutical agent, were put on trial, the

former for having prescribed orally and without indicating the dose, the latter for having made up without prescription in writing a preparation of "phosphorated cod liver oil" (*olio di fegato di merluzzo fosforato*) which, contained in a bottle and exhibited thereafter to three children for the period of four days and in the dose of one teaspoonful per diem, caused their speedy death from the excessive quantity of phosphorus ingested. The Public Prosecutor contended that Pezzotta's responsibility lay in the fact that he had entrusted the preparation of a drug containing a powerful poison to a pharmacist without the formula and instructions as to use which are required by law, and that Beltrami's responsibility consisted in his having made up the prescription "arbitrariamente" (arbitrarily) and handed it over to his client without indicating its composition and character, the dose in which it was to be taken, or indeed any of the precautionary marks insisted on by the "regolamento sanitario." The accused were defended by able counsel drawn from the Milanese and Bergamasque bars whose contention was that the true cause of the death of the first child had not been juridically proven and that the deaths of the other two were attributable to the negligence of those about them, not to the "imputati" (defendants). Numerous witnesses, including practitioners, professors, and chemists, were called on either side, the whole trial lasting over three days. The court found for the prosecution that both Pezzotta and Beltrami were responsible and condemned the former to imprisonment for two months and 15 days with payment of a fine of 83 francs (£3 6s 8d) and the latter to five months' imprisonment and 750 francs (£30) fine. Both parties were also amerced in costs. As I have often put in evidence, such cases of criminal malpractice seem to survive the most exemplary retribution of the law and—if the supporters of the Santini Bill would only see it—explain and justify the misgivings with which an English speaking *clientèle* regards the consignment of its health (and more) to practitioners among whom such negligence is possible.

"Rectores Magnifici" of Padua and Turin

The University of Padua has just elected as its "Rector Magnificus" its illustrious Professor of Clinical Medicine, Dr Achille De Giovanni—the retiring holder of that office. He had 27 votes against 22 given for his rival Professor Nasini, lecturer on Chemistry. For the similar post vacant in the University of Turin by the death of Dr Cesare Nani, Professor of Legal History, there are several distinguished candidates, among whom the medical names of Mosso and Bizzozzero have been mentioned.

June 5th

EGYPT

(FROM OUR OWN CORRESPONDENT)

Plague in Alexandria

ALL readers of historical medicine know that plague was constantly present in Egypt from the days when Egypt and Greece were tottering towards decay and both shortly to become Roman provinces, until 1844 when Kinglake wrote his admirable "Eöthen" and taught our fathers and grandfathers the delights of Oriental travel. The plague left England in the seventeenth century suddenly and with equal abruptness it disappeared from Egypt, though of late years it has often been in Tripoli, Arabia, and Uganda. Now after 55 years absence it is again in Alexandria and though its coming is still shrouded in some mystery it is assumed that it has reached us by some indirect channel from the Hedjaz. Cholera has come to Egypt so often from the holy places that it seems not unfair to remember that plague has been present in Jeddah for three seasons and that there have been more than 100 deaths from it there during the last three months. The modern Alexandrian story is as follows. On May 2nd a Greek boy, about 14 years of age, was admitted into the Greek Hospital with fever and a right axillary bubo. Plague was suspected, but as the case was decided by the clinical and bacteriological experts not to fulfil all the necessary conditions and as there was no evidence of the disease then existing in Egypt it was not officially reported. However, the medical officer of health took the precaution of tracing the patient's surroundings. He lived in an inn

tuberculous and non tuberculous convicts are herded together. Especially is this the case in the winter months when the greatest number of convicts is crowded into the smallest possible space in order to economise fuel and blankets.

Conclusion of the Beef Court

The above court decides that the testimony is conclusive that the refrigerated beef and the canned beef were in good condition when delivered to the Government and contained so until issued to the troops, except in special instances where the deterioration was due to accidental conditions in transportation or to the influence of the tropical climate. The report admits the liability of refrigerated beef to emit gaseous when removed from the ice chests. The court finds the charges of "embalming," the beef to have been substantiated by the testimony, and says that no chemicals were used to preserve it. It also finds that it would have been impracticable to secure beef on the hoof for the Cuban campaign. The finding is likewise in opposition to the assertion of General Miles that the use of the beef was an experiment. Much attention is given to the charges concerning the canned roast beef, and it is stated that the testimony proves it to have been wholesome and nutritious when used in moderation and under favourable circumstances. The position is taken that too much of this article of food was supplied to the men and that under the circumstances it was unpalatable and found undesirable as a continuous ration. The fact is set forth that the canned roast beef had not been used to any appreciable extent before the beginning of this war, and it is therefore regarded as an untimed ration practically. In view of this fact the Commissary General of Subsistence is criticised for the purchase of the meat for wholesale quantities. As to the character of the meat for wholesomeness and nutrition the reports of Professor Atwater and Professor Chittenden are quoted at length sustaining the claims in this respect. The findings of the court are that the meat was "doctored," that it was the beef of commerce, that there was no more neglect than was incident to the hurried preparations for war, that the inspection, while generally according to regulations, was not always up to requirements, and that the sickness of the troops was not to any great degree occasioned by the use of either the canned or the refrigerated beef. In the opinion of the Army Commission the following facts substantiated the causes of disease. The principal reasons for the disease prevalent in the army were exposure to extreme alternations of daily temperature, to inclement downpours of rain, and to the malarial influences peculiar to the most dangerous portion of the island of Cuba at the unhealthiest season of the year. Lack of shelter from sun and rain and irregular, inadequate, and insufficient supplies of food, fuel, and clothing, due to want of transportation, also increased in the sick report which all accounts agree as having taken place between July 8th and 10th, and after the command had been subjected for some days to the fatigue and exposure incident to the digging and manning of trenches, the maintenance of an outpost service, and the conduct of siege operations. That the sickness was due to particular articles of ration rather than to the character and components of the ration itself and its general unsuitability to existing conditions is not clear. This is shown by the fact that though there is a very marked difference in the different commands of the army the sick rate was very much the same in all. A division, for instance, which subsisted largely on bacon and used no canned beef and but little refrigerated beef suffered as seriously from sickness as another division which used the canned fresh meat and received also considerable quantities of refrigerated beef. Having regard, therefore, to the testimony adduced as to the causes which are admitted to have operated to produce intestinal disorders, such as the eating of tropical fruits, the use of unboiled and unfiltered water, malarial poisoning, exposure to daily rains and the considerable diurnal variations of the temperature and the like, the court finds it impossible to conclude that either the canned fresh beef or the refrigerated beef appeared to any considerable extent as causes of intestinal troubles.

Mortality in the Philippines

Surgeon General Stenberg has just received from Manila a report giving the mortality record of the Philippines for the

frequenting by Jews and other travellers, none of whom could be traced to Jeddah or to the pilgrimage. On May 16th another Greek was admitted into the Greek Hospital with a left axillary bubo, deltidum, and a temperature of 105.8° F. This proved to be an undoubted case of plague and was at once published. Since then there have been six cases, all of bubonic plague—four natives and two Greeks—all living in the poorest quarters of the town and not far removed from each other, but the cases are not infrequently connected. There are also the stories usual in plague-towns of rats having been seen baying and dying without apparent cause. So far the cases bear out the theory that the propagation of the disease depends more upon place than upon direct transmission from one individual to another. All the eight cases, if we are to accept the original doubtful pattern, have been of the bubonic type, and the foregoing much less than the pneumonic or septemic variety. To those who know nothing practically about plague it may be justifiable to point out for comparison that tubercle may be a local manifestation, such as "a post-mortem finger," or the bacilli may enter the bronchus and set up tuberculosis of the lung, or, again, the microbe may directly enter the blood current and set up a general poisoning, acute miliary tubercle. Of these three it is only the second which is dangerous from the contagious point of view. Now, the plague bacilli may enter an abrasion on the hand or foot and produce local poisoning, evidenced by a bubo in the armpit or the groin, but the bacilli are safely locked up and cannot very well spread the disease, for when the bubo suppurates the pyogenic germs are found to have killed the plague cocci. But if the cocci bacilli enter the respiratory passages the pneumonic form is produced and the attendants are at once in danger. If the microbe gets admission into the circulation an acute septicemic variety occurs which usually kills the patient before he has much time to spread the disease.

Typhalictic Malaries

The Quarantine Board at Alexandria has had some special meetings and has decided by a large majority to insist upon the medical examination of all passengers and baggage before sailing from Alexandria and in addition to the disinfection of the soiled linen of all third-class travellers. A few Greeks have left the city for Europe, but there has been no general flight or panic. Sir John Rogers and Pinching Bey are at Alexandria, superintending sanitary measures with their well known energy and Dr. Bittar is also there to assist in bacteriological investigations. The sick are rigorously isolated and their dwellings places are very carefully disinfected, some of their effects being destroyed, and their friends and associates are closely watched. One of the patients was found to have in the house of a landress and all her customers had to be inspected. There is no plague in any other part of Egypt and there is no increase in the death-rate either in Alexandria or elsewhere. Everything tends to the belief that the poison is localised and can be eradicated.

The Plague

There has been no plague among pilgrims this year, no suspicion of it at Tor and the rates accounts all say that there is now no longer plague at Jeddah.

Cairo, May 29th.

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Convicts and Philistines

At the recent Prison Congress in New Orleans Dr. Blake, physician inpector at the Alabama Penitentiary, called attention to the fact that philistines are greatly on the increase in prisons in the South. Taking his own State he quoted statistics to show that in 16 years the percentage of convicts dying from philistines had risen from 17 per cent. above 50 per cent. of the deaths in the penitentiary had been from that disease. Dr. Blake quoted figures from Mississippi, Texas Georgia Virginia and other States, going to show that philistines had steadily increased among the prison population. In Texas in 1898 two-thirds of the total number of deaths of convicts were caused by philistines. The trouble, according to Dr. Blake, lies in the fact that

five years ending 1898. It is based on official Spanish reports of the Christian population and those non-Christians who were Spanish subjects. It shows that at Manila among 315,571 inhabitants the average mortality was 26.2 per 1000. At Iloilo it was 24.4 per 1000. In the island of Negros, among a population of 321,777, it was 22.4 per 1000. The lowest death rate was at Mariannas, it being only 10.4, while the highest, at Cagayan, was stated as 59.9 per 1000. Compared with statistics of other countries given by Professor Richmond Mayo-Smith of Columbia University, the figures relating to the Philippines show that in some parts of the islands the death rate was exceedingly low, while in other parts it was very high. Professor Mayo-Smith said that the census of 1890 showed a death rate in the United States per 1000 of 17 for native-born whites of native parentage, 24.42 for native-born whites of foreign parentage, 19.85 for foreign born whites, and 19.57 for coloured people. In 1893 the statistics showed the following death rates in the countries named: Italy, 25.3; Germany, 24.6; England, 19.4; United Kingdom, 19.1 per 1000. With reference to the deaths of soldiers in tropical countries Professor Mayo-Smith says that the death rate in the British army in 1891 was 4.7 at home, 13.5 abroad. In Ceylon 44 out of 1000 soldiers died in the first year, 48 in the second, and 49 in the third. Out of 1000 soldiers in Jamaica 77 died during the first year, 87 during the second, and 93 during the third year.

Hospital for Phthisical Sailors of the Merchant Marine

The Surgeon General of the Marine Hospital Service is making preparations for the treatment of all sailors of the merchant marine who are suffering from tuberculosis at the new marine hospital now in course of construction on the abandoned military reservation at Fort Stanton, New Mexico. This reservation contains about 10,240 acres and the buildings on it are being repaired and will be fitted up as a sanatorium for the treatment of tuberculosis. The hospital is to be furnished with modern hospital furniture and supplied with all modern instruments and apparatus for the scientific treatment of phthisis. The benefit of the outdoor life in this climate which is so favourable is expected to have a most marked effect upon the patients. It will be managed on the same plan as the National Soldiers' Home. Light employment will be given to those who desire it and the many acres surrounding the hospital will be put under cultivation, the patients raising the better part of the necessities required for food.

May 18th.

Obituary.

JOHN GEORGE SINCLAIR COGHILL, M.D.,
F.R.O.P. EDIN., M.R.O.P. LOND.

DR J. G. SINCLAIR COGHILL, who died at Ventnor, Isle of Wight, on June 5th, was a man of many attainments but was best known to the medical profession and the general public in connexion with his work at the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor. He had for many years been senior physician to this hospital. Dr Coghill was in his sixty-fifth year and belonged to a Scotch family. His father, who had been in a Highland regiment and had fought in Spain in the British Legion under General Sir George De Laoy Evans from 1835 to 1837, was a well known resident in Edinburgh some 40 years ago, a fine example of the retired military man, full of kindly humour and very popular among a wide circle of acquaintances. Dr Coghill studied medicine in Edinburgh and had a distinguished career as an undergraduate, taking gold medals in anatomy, midwifery, and medical jurisprudence. While he was still at class work the Russian war broke out, and he interrupted his studies to volunteer as a surgeon's assistant in the navy, the result being that he served in the Baltic Fleet and received a medal. In 1857 he graduated as M.D. (with honours) at Edinburgh University, and in 1864 was admitted F.R.O.P. Edin. In 1868 he was appointed demonstrator of anatomy in Glasgow University under the late Professor Allen Thomson, in which capacity he proved himself an able lecturer and teacher. In 1861 he resigned this position in order to proceed to Shanghai, his successor as demonstrator being Dr John Cleland who on Professor Allen Thomson's retirement in 1877

was appointed to the vacant chair. Dr Coghill remained several years in Shanghai, becoming ultimately municipal medical officer and consulting physician to the General Hospital. On his return to this country he temporarily conducted the midwifery class in Edinburgh University after the death of Sir James Simpson in 1870, and lectured on pathology and pathological anatomy in the Edinburgh Medical School from 1873 to 1876. He then joined the staff of the Royal National Hospital for Consumption where he spent the remainder of his life. An account of his method of treating phthisis will be found in a paper which was read by him in Berlin on May 26th at the International Congress on Tuberculosis and was published in THE LANCET of June 3rd (p. 1479). His first contribution to our columns appeared just 40 years ago. It was a report of an operation for vesico-vaginal fistula and was printed in THE LANCET of May 7th, 1859. Later in the same year he published in our columns a course of lectures on the Peripheral Nervous System delivered in Glasgow University. Dr Coghill was a Vice-President of the British Gynaecological Society and a Vice-President (Section of Therapeutics) of the ninth International Medical Congress held at Washington in 1887. His death was sadly sudden. On his return from Berlin on June 2nd, apparently in perfect health, he was seized suddenly with gastrointestinal disturbance. This was followed on June 3rd and 4th by hæmatemesis and melæna, and on June 5th symptoms of perforation of the stomach supervened, from which he died.

WILLIAM ROOCROFT, J.P., M.R.O.S. END, L.S.A.

A PROMINENT and well known figure has been removed from amongst the medical men of Wigan by the death of Mr William Roocroft which occurred at Brondesbury villas, Kilburn, London, on May 28th. Deceased was in his seventieth year. He was born at Coppull, near Wigan, on July 5th, 1829, and was educated at Standish Grammar School under the Rev Mr Price. He became a student of the Liverpool School of Medicine and afterwards of King's College, London, qualifying in 1852, when he became a M.R.O.S. Eng. and L.S.A. Lond. The same year he was appointed house surgeon to the then existing Wigan Dispensary—a post he held until he commenced practice on his own account in 1854. He became known in the district as an operating surgeon and soon became surgeon to several large collieries and clubs in the town. He was one of the honorary medical officers to the Royal Albert Edward Infirmary, Wigan, retiring in 1884, when he was placed on the consulting staff, his place on the acting staff being filled by his son, Mr William Mitchell Roocroft. Mr Roocroft was a keen sportsman and was for 30 years a member of the Aspull Hunt. He was a member of the Wigan Town Council for a few years, but suffering defeat in 1868 he never again sought re-election. In 1870 he was placed on the Commission of Peace for the borough of Wigan and for a long period took an active part in magisterial work, often acting as presiding magistrate. He was a man of striking personality, brusque in manner, never hesitating to give expression "to the faith that was within," sometimes to the annoyance of his friends, but with all this he was a most sociable friend. Being one of the old school of general practitioners and holding no medical degree he would rightly insist on being called "Mr" (and not "Dr.") Roocroft, sometimes to the amusement of his younger professional friends who loved to hear him emphasise the term "Mr." Mr Roocroft, who was joined in practice by his son (Mr W. M. Roocroft), had been in failing health for the past four or five years and two years ago left Wigan for the south of England, passing part of the time in Eastbourne and the last few months at Kilburn, where he died, leaving a widow, one son, and a daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced.—Dr A. Ziegler, Chief Surgeon of the Swiss army.—Dr Giovanni Invernizzi, Professor of Midwifery and Gynaecology in the University of Padua.—Dr A. Zinnis, Professor of Children's Diseases in the University of Athens.—Dr Affonso Ramos, Director of the Federal Bacteriological Laboratory, Brazil.—Dr Ezequiel Correia dos Santos, formerly Professor of Pharmacology in the Rio-de Janeiro University.—Dr R. H. Plummer, Professor of Anatomy in the Cooper Medical College, San Francisco.

REGISTRATION

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION

The fine weather during the past week brought out one great defect of the new Council chamber, the absence of all proper ventilation. The effect of this is aggravated by the glass roof of the room, through which the rays of the sun stream down on the devoted members and especially on the President. On Monday the temperature of the Council chamber was 75° F. The members kept remarkably cool considering all things, but it is understood that before the session closes a committee will be appointed to deal with this question. Merely, no pathological sequelae have resulted so far, while it would almost seem as if the effect had been to favour the coolness and equanimity of the members.

sharp conduct with the representatives of the English Conjoint Board. The conduct became more complicated by Dr Church, himself a member of the Education Committee, joining Mr Bryant and Sir Dyce Duckworth in defending the right of the corporations to fix the curriculum without consulting the wishes of the Council. In the end the committee triumphed. Sir J. Batty Tuke was no doubt right in his main contention, but went a little too far in charging the Conjoint Colleges of England with disloyalty to the General Medical Council. They did not deserve this charge.

The work of the Committee upon the subject of Medical Aid and Friendly Societies, of which Dr Glover is chairman, will call for more particular notice. There will be little difference of opinion as to the great importance of a board of consultation for the settlement of questions in dispute between the profession and the friendly societies, and the committee will deserve the support and thanks of the profession. It is can bring to the discussion for settlement, as Mr Bryant maintains it can.

The session of the Council up to the time of our going to press retains the character of having been one of the liveliest and longest on record. On the whole, the character of the debates has been well sustained. The impending withdrawal of Dr. Church on account of his election as President of the Royal College of Physicians of London is much regretted. His practical judgment and his firmness in standing for what he thinks right have been found very useful, especially in the Education Committee. There are other bodies which do not object to the President's being on the General Medical Council but I think that the Council is great and it was scarcely large enough for its work.

We have referred to the burden and heat of the day, and have indicated the patience with which these have been borne by the members of the General Medical Council. It is a severity of their labours has been varied by some pleasant social gatherings. At least two very general banquets must be mentioned, of which the respective hosts were the President of the Royal College of Physicians of London and the President of the General Medical Council. At the latter the Clerk of the Privy Council, and the President of the Royal College of Physicians, Sir William Priestley, Mr Walsellhouse, Sir Walter Roget, Sir William Priestley, and others

THE COUNCIL met to-day, Sir William Tuckwell, President being in the chair, and resumed the work of the session

The work of committees has seldom been more arduous than in the recent session. The Education Committee has sat three or four days almost consecutively. The task of deciding on the merits of different preliminary examinations has been one of the most difficult which has fallen upon those engaged in it.

The Council proceeded to the consideration of the case of Samuel Bingham Shkelton, of 17, Compton avenue, Barking-road, East Ham, registered in Ireland Nov. 26th, 1874, as The F. Coll. Surg. Ltd., 1872, who had been summoned to appear before the Council to answer the following charges as formulated by the Council's solicitor:

be a very difficult one, affecting many interests and schools. Much praise is due in this connection to Sir J. Batty Tuke and to Dr Donald MacAlister, but many questions remain unanswered. The position of medical practice, as registered, is not a very satisfactory one, and the position of the unregistered person to whom the law refers is not a very satisfactory one. The position of the unregistered person to whom the law refers is not a very satisfactory one.

is demanded and it is felt that an independent report from experts on the subjects in dispute will be expected for the Council has to wait longer than responses was made and received. On the name of the accused predecessor being called to

reliable when it comes to the recognition of science teaching in schools and the danger of losing one of the five years for medical study. Here, it will be seen, it came into somewhat with the question of the recognition of science teaching in schools and the danger of losing one of the five years for medical study. Here, it will be seen, it came into somewhat

five years ending 1898. It is based on official Spanish reports of the Christian population and those non-Christians who were Spanish subjects. It shows that at Manila among 315,571 inhabitants the average mortality was 26.2 per 1000. At Iloilo it was 24.4 per 1000. In the island of Negros, among a population of 321,777, it was 22.4 per 1000. The lowest death rate was at Mariannas, it being only 10.4, while the highest, at Cagayan, was stated as 59.9 per 1000. Compared with statistics of other countries given by Professor Richmond Mayo Smith of Columbia University, the figures relating to the Philippines show that in some parts of the islands the death rate was exceedingly low, while in other parts it was very high. Professor Mayo-Smith said that the census of 1890 showed a death rate in the United States per 1000 of 17 for native born whites of native parentage, 24.42 for native born whites of foreign parentage, 19.85 for foreign born whites, and 19.57 for coloured people. In 1893 the statistics showed the following death rates in the countries named: Italy, 25.3; Germany, 24.6; England, 19.4; United Kingdom, 19.1 per 1000. With reference to the deaths of soldiers in tropical countries Professor Mayo-Smith says that the death rate in the British army in 1891 was 4.7 at home, 13.5 abroad. In Ceylon 44 out of 1000 soldiers died in the first year, 48 in the second, and 49 in the third. Out of 1000 soldiers in Jamaica 77 died during the first year, 87 during the second, and 93 during the third year.

Hospital for Phthical Sailors of the Merchant Marine

The Surgeon General of the Marine Hospital Service is making preparations for the treatment of all sailors of the merchant marine who are suffering from tuberculosis at the new marine hospital now in course of construction on the abandoned military reservation at Fort Stanton, New Mexico. This reservation contains about 10,240 acres and the buildings on it are being repaired and will be fitted up as a sanatorium for the treatment of tuberculosis. The hospital is to be furnished with modern hospital furniture and supplied with all modern instruments and apparatus for the scientific treatment of phthisis. The benefit of the outdoor life in this climate which is so favourable is expected to have a most marked effect upon the patients. It will be managed on the same plan as the National Soldiers' Home. Light employment will be given to those who desire it and the many acres surrounding the hospital will be put under cultivation, the patients raising the better part of the necessities required for food.

Obituary.

JOHN GEORGE SINCLAIR COGHILL, M.D.,
F.R.O.P. EDIN., M.R.C.P. LOND.

Dr J. G. SINCLAIR COGHILL, who died at Ventnor, Isle of Wight, on June 5th, was a man of many attainments but was best known to the medical profession and the general public in connexion with his work at the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor. He had for many years been senior physician to this hospital. Dr Coghill was in his sixty-fifth year and belonged to a Scotch family. His father, who had been in a Highland regiment and had fought in Spain in the British Legion under General Sir George De Lacy Evans from 1835 to 1837, was a well-known resident in Edinburgh some 40 years ago, a fine example of the retired military man, full of kindly humour and very popular among a wide circle of acquaintances. Dr Coghill studied medicine in Edinburgh and had a distinguished career as an undergraduate, taking gold medals in anatomy, midwifery, and medical jurisprudence. While he was still at class work the Russian war broke out, and he interrupted his studies to volunteer as a surgeon's assistant in the navy, the result being that he served in the Baltic Fleet and received a medal. In 1857 he graduated as M.D. (with honours) at Edinburgh University, and in 1864 was admitted F.R.O.P. Edin. In 1868 he was appointed demonstrator of anatomy in Glasgow University under the late Professor Allen Thomson, in which capacity he proved himself an able lecturer and teacher. In 1861 he resigned this position in order to proceed to Shanghai, his successor as demonstrator being Dr John Cleland who on Professor Allen Thomson's retirement in 1877

was appointed to the vacant chair. Dr Coghill remained several years in Shanghai, becoming ultimately municipal medical officer and consulting physician to the General Hospital. On his return to this country he temporarily conducted the midwifery class in Edinburgh University after the death of Sir James Simpson in 1870, and lectured on pathology and pathological anatomy in the Edinburgh Medical School from 1873 to 1876. He then joined the staff of the Royal National Hospital for Consumption where he spent the remainder of his life. An account of his method of treating phthisis will be found in a paper which was read by him in Berlin on May 28th at the International Congress on Tuberculosis and was published in THE LANCET of June 3rd (p. 1479). His first contribution to our columns appeared just 40 years ago. It was a report of an operation for vesico-vaginal fistula and was printed in THE LANCET of May 7th, 1859. Later in the same year he published in our columns a course of lectures on the Peripheral Nervous System delivered in Glasgow University. Dr Coghill was a Vice-President of the British Gynaecological Society and a Vice-President (Section of Therapeutics) of the ninth International Medical Congress held at Washington in 1887. His death was sadly sudden. On his return from Berlin on June 2nd, apparently in perfect health, he was seized suddenly with gastrointestinal disturbance. This was followed on June 3rd and 4th by hæmatemesis and melæna, and on June 5th symptoms of perforation of the stomach supervened, from which he died.

WILLIAM ROOCROFT, J.P., M.R.O.S. ENG., L.S.A. :

A PROMINENT and well-known figure has been removed from amongst the medical men of Wigan by the death of Mr William Roocroft which occurred at Brondesbury Villas, Kilburn, London, on May 28th. Deceased was in his seventieth year. He was born at Coppull, near Wigan, on July 5th, 1829, and was educated at Standish Grammar School under the Rev Mr Price. He became a student of the Liverpool School of Medicine and afterwards of King's College, London, qualifying in 1852, when he became a M.R.O.S. Eng. and L.S.A. Lond. The same year he was appointed house surgeon to the then existing Wigan Dispensary—a post he held until he commenced practice on his own account in 1854. He became known in the district as an operating surgeon and soon became surgeon to several large collieries and clubs in the town. He was one of the honorary medical officers to the Royal Albert Edward Infirmary, Wigan, retiring in 1884, when he was placed on the consulting staff, his place on the acting staff being filled by his son, Mr William Mitchell Roocroft. Mr Roocroft was a keen sportsman and was for 30 years a member of the Aspull Hunt. He was a member of the Wigan Town Council for a few years, but suffering defeat in 1868 he never again sought reelection. In 1870 he was placed on the Commission of Peace for the borough of Wigan and for a long period took an active part in magisterial work, often acting as presiding magistrate. He was a man of striking personality, brusque in manner, never hesitating to give expression "to the faith that was within," sometimes to the annoyance of his friends, but with all this he was a most sociable friend. Being one of the old school of general practitioners and holding no medical degree he would rightly insist on being called "Mr" (and not "Dr"). Roocroft, sometimes to the amusement of his younger professional friends who loved to hear him emphasise the term "Mr" Mr Roocroft, who was joined in practice by his son (Mr W. M. Roocroft), had been in failing health for the past four or five years and two years ago left Wigan for the south of England, passing part of the time in Eastbourne and the last few months at Kilburn, where he died, leaving a widow, one son, and a daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced.—Dr A. Ziegler, Chief Surgeon of the Swiss army.—Dr Giovanni Invernardi, Professor of Midwifery and Gynaecology in the University of Padua.—Dr A. Zinnla, Professor of Children's Diseases in the University of Athens.—Dr Afonso Ramos, Director of the Federal Bacteriological Laboratory, Brazil.—Dr Ezequiel Correia dos Santos, formerly Professor of Pharmacology in the Rio-de Janeiro University.—Dr R. H. Plummer, Professor of Anatomy in the Cooper Medical College, San Francisco.

five years ending 1898. It is based on official Spanish reports of the Christian population and those non-Christians who were Spanish subjects. It shows that at Manila among 315,571 inhabitants the average mortality was 26.2 per 1000. At Iloilo it was 24.4 per 1000. In the island of Negros, among a population of 321,777, it was 22.4 per 1000. The lowest death rate was at Mariannas, it being only 10.4, while the highest, at Cagayan, was stated as 59.9 per 1000. Compared with statistics of other countries given by Professor Richmond Mayo Smith of Columbia University, the figures relating to the Philippines show that in some parts of the islands the death rate was exceedingly low, while in other parts it was very high. Professor Mayo-Smith said that the census of 1890 showed a death rate in the United States per 1000 of 17 for native-born whites of native parentage, 24.42 for native-born whites of foreign parentage, 19.95 for foreign-born whites, and 19.57 for coloured people. In 1893 the statistics showed the following death rates in the countries named: Italy, 25.3; Germany, 24.6; England, 19.4; United Kingdom, 19.1 per 1000. With reference to the deaths of soldiers in tropical countries Professor Mayo-Smith says that the death rate in the British army in 1891 was 4.7 at home, 13.5 abroad. In Ceylon 44 out of 1000 soldiers died in the first year, 48 in the second, and 49 in the third. Out of 1000 soldiers in Jamaica 77 died during the first year, 87 during the second, and 93 during the third year.

Hospital for Phthisical Sailors of the Merchant Marine

The Surgeon General of the Marine Hospital Service is making preparations for the treatment of all sailors of the merchant marine who are suffering from tuberculosis at the new marine hospital now in course of construction on the abandoned military reservation at Fort Stanton, New Mexico. This reservation contains about 10,240 acres and the buildings on it are being repaired and will be fitted up as a sanatorium for the treatment of tuberculosis. The hospital is to be furnished with modern hospital furniture and supplied with all modern instruments and apparatus for the scientific treatment of phthisis. The benefit of the outdoor life in this climate which is so favourable is expected to have a most marked effect upon the patients. It will be managed on the same plan as the National Soldiers' Home. Light employment will be given to those who desire it and the many acres surrounding the hospital will be put under cultivation, the patients raising the better part of the necessities required for food.

May 18th.

Obituary.

JOHN GEORGE SINCLAIR COGHILL, M.D.,
F.R.O.P. EDIN., M.R.C.P. LOND.

DR. J. G. SINCLAIR COGHILL, who died at Ventnor, Isle of Wight, on June 5th, was a man of many attainments but was best known to the medical profession and the general public in connexion with his work at the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor. He had for many years been senior physician to this hospital. Dr. Coghill was in his sixty-fifth year and belonged to a Scotch family. His father, who had been in a Highland regiment and had fought in Spain in the British Legion under General Sir George De Laoy Evans from 1835 to 1837, was a well-known resident in Edinburgh some 40 years ago, a fine example of the retired military man, full of kindly humour and very popular among a wide circle of acquaintances. Dr. Coghill studied medicine in Edinburgh and had a distinguished career as an undergraduate, taking gold medals in anatomy, midwifery, and medical jurisprudence. While he was still at class work the Russian war broke out, and he interrupted his studies to volunteer as a surgeon's assistant in the navy, the result being that he served in the Baltic Fleet and received a medal. In 1857 he graduated as M.D. (with honours) at Edinburgh University, and in 1864 was admitted F.R.O.P. Edin. In 1858 he was appointed demonstrator of anatomy in Glasgow University under the late Professor Allen Thomson, in which capacity he proved himself an able lecturer and teacher. In 1861 he resigned this position in order to proceed to Shanghai, his successor as demonstrator being Dr. John Cleland who on Professor Allen Thomson's retirement in 1877

was appointed to the vacant chair. Dr. Coghill remained several years in Shanghai, becoming ultimately municipal medical officer and consulting physician to the General Hospital. On his return to this country he temporarily conducted the midwifery class in Edinburgh University after the death of Sir James Simpson in 1870, and lectured on pathology and pathological anatomy in the Edinburgh Medical School from 1873 to 1876. He then joined the staff of the Royal National Hospital for Consumption where he spent the remainder of his life. An account of his method of treating phthisis will be found in a paper which was read by him in Berlin on May 26th at the International Congress on Tuberculosis and was published in THE LANCET of June 3rd (p. 1479). His first contribution to our columns appeared just 40 years ago. It was a report of an operation for vesico-vaginal fistula and was printed in THE LANCET of May 7th, 1859. Later in the same year he published in our columns a course of lectures on the Peripheral Nervous System delivered in Glasgow University. Dr. Coghill was a Vice-President of the British Gynaecological Society and a Vice-President (Section of Therapeutics) of the ninth International Medical Congress held at Washington in 1887. His death was sadly sudden. On his return from Berlin on June 2nd, apparently in perfect health, he was seized suddenly with gastrointestinal disturbance. This was followed on June 3rd and 4th by hæmatemesis and melena, and on June 5th symptoms of perforation of the stomach supervened, from which he died.

WILLIAM ROOCROFT, J.P., M.R.O.S. ENG., L.S.A.

A PROMINENT and well-known figure has been removed from amongst the medical men of Wigan by the death of Mr. William Roocroft which occurred at Brondesbury villas, Kilburn, London, on May 28th. Deceased was in his seventieth year. He was born at Coppull, near Wigan, on July 5th, 1829, and was educated at Standish Grammar School under the Rev. Mr. Price. He became a student of the Liverpool School of Medicine and afterwards of King's College, London, qualifying in 1852, when he became a M.R.O.S. Eng. and L.S.A. Lond. The same year he was appointed house surgeon to the then existing Wigan Dispensary—a post he held until he commenced practice on his own account in 1854. He became known in the district as an operating surgeon and soon became surgeon to several large collieries and clubs in the town. He was one of the honorary medical officers to the Royal Albert Edward Infirmary, Wigan, retiring in 1884, when he was placed on the consulting staff, his place on the acting staff being filled by his son, Mr. William Mitchell Roocroft. Mr. Roocroft was a keen sportsman and was for 30 years a member of the Aspull Hunt. He was a member of the Wigan Town Council for a few years, but suffering defeat in 1868 he never again sought re-election. In 1870 he was placed on the Commission of Peace for the borough of Wigan and for a long period took an active part in magisterial work, often acting as presiding magistrate. He was a man of striking personality, brusque in manner, never hesitating to give expression "to the faith that was within," sometimes to the annoyance of his friends, but with all this he was a most sociable friend. Being one of the old school of general practitioners and holding no medical degree he would rightly insist on being called "Mr." (and not "Dr.") Roocroft, sometimes to the amusement of his younger professional friends who loved to hear him emphasise the term "Mr." Mr. Roocroft, who was joined in practice by his son (Mr. W. M. Roocroft), had been in falling health for the past four or five years and two years ago left Wigan for the south of England, passing part of the time in Eastbourne and the last few months at Kilburn, where he died, leaving a widow, one son, and a daughter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced.—Dr. A. Ziegler, Chief Surgeon of the Swiss army.—Dr. Giovanni Invernardi, Professor of Midwifery and Gynaecology in the University of Padua.—Dr. A. Zinnia, Professor of Children's Diseases in the University of Athens.—Dr. Afonso Ramos, Director of the Federal Bacteriological Laboratory, Brazil.—Dr. Ezequiel Correa dos Santos, formerly Professor of Pharmacology in the Rio de Janeiro University.—Dr. R. H. Plummer, Professor of Anatomy in the Cooper Medical College, San Francisco.

sharp conflict with the representatives of the English Conjoint Board. The conflict became more complicated by Dr. Church, himself a member of the Education Committee, joining Mr. Bryant and Sir Dyce Duckworth in defending the right of the corporations to fix the curriculum without consulting the wishes of the Council. In the end the committee triumphed. Sir J. Batty Tuke was no doubt right in his main contention, but went a little too far in charging the Conjoint Colleges of England with disloyalty to the General Medical Council. They did not deserve this charge.

The work of the Committee upon the subject of Medical Aid and Friendly Societies, of which Dr. Glover is chairman, will call for more particular notice. There will be little difference of opinion as to the great importance of a board of conciliation for the settlement of questions in dispute between the profession and the friendly societies, and the committee well deserves the support and thanks of the profession if it can bring into the discussion for settlement, as Mr. Bryant maintains it can, the question of a wage limit. Scarcely less important is the resolution passed by the Council on the recommendation of the committee strongly disapproving of the system of canvassing and advertising by which medical and associations connected with insurance business are pushed.

A very good thing was done on Wednesday on the motion of Dr. Bruce. The Penal Cases Committee was enlarged. The proposal to do this has often been made before unsuccessfully. The responsibilities of this committee are great and it was scarcely large enough for its work.

We have referred to the burden and heat of the day, and have indicated the patience with which these have borne by the members of the General Medical Council. It is gratifying to know, if rumour may be trusted, that the severity of their labours has been varied by some pleasant social gatherings. At least two very genial banquets must be mentioned, of which the respective hosts were the President of the Royal College of Physicians of London and the President of the General Medical Council. At the latter the Clerk of the Royal Council and the President of the Royal College of Physicians were present, as were also Mr. Wychehouse, Sir Walter Foster, Sir William Pridmore, and others.

THURSDAY, JUNE 1ST
The Council met to-day. Sir WILLIAM TURNER, President, being in the chair, and resumed the work of the session.

The Council proceeded to the consideration of the case of Samuel Bligham Sholeman, of 17, Compton Avenue, Barking Road, East Ham, registered in Ireland Nov. 26th, 1879, as L.R.C.S. (Irel., 1872), who had been summoned to appear before the Council to answer the following charges formulated by the Council's solicitor:—
1. That in the year 1885 he aided and assisted an unqualified person named Julian Averford Howard to procure himself to be registered under the Medical Act, 1858, under the name and with some of the regular qualifications of one Edward Joseph Burgess, by making and procuring false and fraudulent representations, and procuring the said unqualified person to assume the position of a duly qualified and registered medical practitioner and to carry on medical practice as though he had been duly qualified, thereby obtaining a licence to practise, and a certificate of registration for the said Julian Averford Howard in the name of the said Edward Joseph Burgess, by the Irish Branch of the Council, which certificate is now in the possession of the Council.

On the name of the accused practitioner being called response was made and accordingly the case proceeded. Mr. FARNHAM, the Council's solicitor, said the inquiry had been given to Mr. Sholeman by Mr. Sholeman's show. In his letter Mr. Farnham said, "I am sorry to hear of the case."

THE GENERAL MEDICAL COUNCIL OF REGISTRATION

The fine weather during the past week, brought out one great defect of the new Council chamber, the absence of all proper ventilation. The effect of this is aggravated by the glass roof of the room, through which the rays of the sun stream down on the devoted members and especially of the President. The members kept remarkably cool considering all things, but it is understood that before the session closes a committee will be appointed to deal with this question. Meritally, no pathological questions have resulted so far, while it would almost seem as if the effect had been to favour the coolness and equanimity of the members.

The session of the Council up to the time of our going to press retains the character of having been one of the liveliest and longest on record. On the whole, the character of the debates has been well sustained. The impending withdrawal of Dr. Church on account of his election as President of the Royal College of Physicians of London is much regretted. His practical judgment and his firmness in conducting for what he thinks right have been found very useful, especially in the Education Committee. There are sister bodies which do not object to their presidents being on the General Medical Council, but the College in Hall Mall is very emphatic on this point. Oxford University will be represented by Dr. J. R. Payne in the next Council and the Royal College of Physicians of London will monopolise the statesman like and judicial qualities of Dr. Church.

Nearly three days were occupied in hearing penal cases and four names were removed from the Register. On a future occasion we may have to point out some new features in the disciplinary action of the Council. Meantime our readers will do well to scan pretty closely the cases dealt with. The offences brought to light, and the methods in dealing with them of the Council are both worthy of attention. In some cases the judgment of the Council has been deferred to give time for the abandonment of practices of which it disapproves—a very proper course, especially when the only alternative is immediate removal from the Medical Register with much uncertainty and difficulty as to restoration.

The work of committees has seldom been more arduous than in the recent session. The Education Committee has sat three or four days almost consecutively. The task of deciding on the merits of different preliminary examinations, and of raising the standard, all found is found to be a very difficult one, affecting many interests and exciting many fears of serious depletion of the medical schools. Much praise is due in this connection to Sir J. Batty Tuke and to Dr. Donald MacAlister, but many questions remain under consideration. More time is demanded and it is felt that an independent report from experts on the subjects in dispute will tend to allay irritation and objection. The Council has conceded both points. We shall have to wait longer than was expected for the result, but it cannot fail to be more reliable when it comes. This committee, too, has had to deal with the question of the recognition of science teaching in schools and the danger of losing one of the five years for medical study. Here, it will be seen, it came into somewhat

under any other name than Nugent and he signed the paper to assist him to get on the Register, fully believing him to be Nugent. He never assisted him in any other way beyond this, that he resided for a time in Rowland's house.

Dr BATEMAN, of the Medical Defence Union, then addressed the Council in support of the charge. He explained how suspicion came to be directed against Rowland and how proceedings against him were thwarted by the fact that he got admission to the Medical Register, and how in the end he was tried and convicted at the Old Bailey for false impersonation and sentenced to three years' imprisonment. Dr Bateman further presented to the Council certain circumstances which he claimed showed that Mr Shekleton was aware of the real identity of Rowland.

While the members of the Council were deliberating in private on the case information was received that Mr Shekleton had presented himself at the office. The Council resumed proceedings in public and gave Mr Shekleton an opportunity to explain. At the outset, in answer to the PRESIDENT, he admitted that he had written a letter stating that he would attend at 2 o'clock—the hour named in the Council's summons—but he was sorry he could not be present earlier owing to miscalculation of the time required to reach the Council's offices by train and omnibus.

The PRESIDENT said that Mr Shekleton must consider it an act of grace on the part of the Council to allow him an opportunity to be heard, particularly as his non appearance at 2 o'clock would tend to disarrange the whole procedure.

Mr SHEKLETON again expressed regret and in reference to the charge against him said that he could not give more explanation than he had given in the letter which he had sent to the Council. He was perfectly aware that the charge was a very serious one against his personal conduct. In answer to further questions he stated that he first knew the man named in the charge some 20 years ago when he was in Gloucestershire. He knew him then only as "the doctor." He was a medical assistant then and he was on speaking terms with "the doctor." It was not until 1890 that he knew his name was Nugent. In that year he saw him at his house in Dumbarton road where he was in practice under the name of Nugent. He had signed the papers in the full belief that he was the man. When the papers were presented to him he had asked how many years had elapsed since he first knew Nugent and had received the reply that it was at least 16 years. He had then said that he could conscientiously sign that he had known Nugent about 16 years. Yet he certainly had not known this man for 16 years as Nugent. He had never known him in connexion with Woolwich. He admitted that the certificate he had given said that he had so known him. The certificate was entirely in his handwriting. No doubt it was written at Nugent's—the supposed Nugent's—dictation. The man had been in practice for eight years under the name of Nugent. He had never heard the name of Rowland in connexion with this man and never had had the slightest suspicion that he was not Nugent.

Strangers were ordered to withdraw and the Council deliberated on the case in private. On the readmission of the public

The PRESIDENT announced that the resolution the Council had come to was—

(a) That the Council do proceed at once to pronounce its judgment on the case. (b) That the charge made against Mr Samuel Bingham Shekleton has been proved to the satisfaction of the Council and (c) That the Council do now judge Mr Samuel Bingham Shekleton to have been guilty of infamous conduct in a professional respect and do direct the Registrar to erase from the Medical Register the name of Mr Samuel Bingham Shekleton.

Mr SHEKLETON withdrew.

The PRESIDENT said he had received two resolutions in connexion with the decision just arrived at.

Dr CHURCH thereupon moved—

That the result of this day's inquiry re Samuel Bingham Shekleton together with a copy of the papers brought before the Council, be communicated to the proper authorities of New South Wales, drawing attention to the statement that Edward Joseph Nugent has been placed on the Colonial Register and is now practising in New South Wales and further to the fact that his name has been erased under Section XIV of the Medical Act, 1858, from the Medical Register of the United Kingdom.

This motion was agreed to.

Mr WILLIAM THOMSON moved "That the Council hereby Unwinds of the action of the Executive Committee in 1858 he whom the Register the name of Edward Joseph University under the name of K Q C P I" capacity he proved himself and were not called upon to. In 1861 he resigned this position.

The PRESIDENT said that in his opinion the motion was unnecessary. Why should they put in their minutes a special motion approving of their doing their duty?

After some further remarks the motion was rejected by 12 votes to 10.

Mr HORSLEY asked if this vote meant that the Council disapproved of the action of the Executive Committee.

Dr McVAIL Most undoubtedly.

Dr MACALISTER We cannot go into what was in the mind of those who voted against the resolution.

Mr HORSLEY Pardon me, Dr MacAlister, but my question was addressed to the President and not to you. I ask the President to rule whether we are to regard the negating of the resolution just rejected as meaning that the Council disapproves of the action of the Executive Committee, because if so I should like at some later period of the session to put ourselves right.

The PRESIDENT I understand that those who voted for the motion did not disapprove of the action of the Executive Committee, but I cannot interpret the opinion of those members of the Council who opposed the motion.

Mr HORSLEY I must say that if you are entitled to interpret the minds of some of us you are entitled to interpret the minds of the rest of us.

The PRESIDENT I would not go so far as that.

Mr BROWN I should like names to be taken down.

Ories of "No, no," greeted this request and the Council proceeded to hear the next case on the programme.

The Case of James Jerome McKay

The Council proceeded to the consideration of the case of James Jerome McKay, of 154A, Wandsworth road, S.W., registered in England, July 17th, 1876, as of Bally Roberts, Fermoyle, County Cork, Mem. Roy Coll Surg Eng, 1876; Lic Roy Coll Phys Lond, 1877, who had been summoned to appear before the Council to answer the following charge as formulated by the Council's solicitor—

That having, as a registered practitioner undertaken, on the order of the coroner to make a proper and complete post-mortem examination of the viscera, head, chest, and abdomen of the body of a dead child named Ernest Mackenzie for the purpose of ascertaining and informing the Coroner's Court of the cause of the death of such child, and not only failed to make the examination which was required, and omitted to ascertain the cause of death, but subsequently deposed before the Coroner's Court (contrary to the facts) that he had ascertained the cause of death by making a complete and careful examination of all the organs of the deceased child. The documents forwarded to the General Medical Council in support of the complaint consist of the information in writing of the said coroner, dated Feb. 4th, 1898, and a certified copy of the depositions taken at the inquest on the death of the said child on Dec. 9th and 12th, 1898. Complaint is also made of Mr McKay's conduct by the Medical Defence Union and they will conduct the case and tender the coroner as a witness.

Mr MCKAY attended in answer to the summons and in reply to a question by the PRESIDENT as to whether he was accompanied by a solicitor or counsel he stated that he was not, but he appeared in support of his own case.

Dr BATEMAN, who appeared for the Medical Defence Union, stated that Mr Braxton Hicks the original complainant, would be unable to attend and that he undertook to conduct the case on his behalf and that of the Medical Defence Union.

Mr FARRELL, solicitor to the Council, read the charge against the accused.

Dr BATEMAN in stating the case mentioned that Mr McKay had been committed for perjury by the coroner, but when the case was tried before Mr Plowden, one of the metropolitan magistrates, that gentleman had treated the matter as one of dispute between two medical men and had dismissed the summons. The charge of perjury brought before Mr Plowden was a criminal charge. That which was now brought before the General Medical Council was a civil charge. The accused could not successfully plead that having been acquitted by Mr Plowden, of the charge of perjury he could not be guilty of the charge under which he was now summoned.

The PRESIDENT said to Mr McKay that he could now state his case and produce his proof.

Mr MCKAY said that since he was before Mr Plowden he had not been in practice. The charge was preferred against him by the Crown and on a judicial examination he was found to be an innocent man. He did not want to say a word against the coroner but he must ask this, Why did not the coroner give him the chance to be present at the second post-mortem examination?

The PRESIDENT You were not asked to be present at the second post-mortem examination?

Mr MCKAY I was not.

Mr TEATE Was that the ground on which you were

acquitted?

Mr McKAY I cannot tell

Mr HORSLEY wanted to know whether Mr McKAY would

abide by an answer previously given by him that he was

perfectly sober when sent for to attend the second post-

mortem examination

Mr McKAY Perfectly sober on that day, sir

Mr HORSLEY—Then I would ask if Mr McKAY fully

understood the gravity of the matter?

Mr McKAY I certainly did, as I stated in open court.

The PRESIDENT You realised the position you were in?

Mr McKAY Certainly sir

The PRESIDENT Is it your defence that Mr Howden

disposed of the matter?

Mr McKAY I am telling you the truth so far as I am

concerned

The Council deliberated on the case in private On the

reconsideration of the public the PRESIDENT announced that the

decision was as follows—

(1) That the Council do proceed at once to pronounce its judgment

on the case (2) That the charge made against Mr James Jerome

McKay has been proved to the satisfaction of the Council and (3) That

the Council do now judge Mr James Jerome McKay to have been

guilty of infamous conduct in a professional respect and do direct the

Banishment to cease from the Medical Register the name of Mr. James

Jerome McKay

On the motion of Dr MACALISTER, seconded by Mr

BRADY, the following report was adopted—

The Business Committee beg leave to report that communication

addressed to the President by the Honorary Secretary of the Royal

Institute of Public Health has been referred to them as being of the

nature of a petition On examination it appears that the communica-

tion has been addressed to the Medical Council under the misapprehen-

sion that the Council is not a medical corporation in the sense intended

by the writer The Committee recommended that the President be

requested to send a reply to the foregoing effect.

The request from the Royal Institute of Public Health was

that the General Medical Council should petition Parliament

in favour of the appointment of a medical officer under the

Board of Education Bill—a measure which has already

passed the House of Lords

Mr MACALISTER, as chairman of the Business Committee,

laid on the table copies of a memorial, dated March 30th,

1899, signed by 385 persons on the subject of the alleged

improper conduct of registered practitioners by part

cipating in the issue of persons not medically registered of

diplomans or certificates testifying, or implying, or that may

be used to testify, or imply, proficiency in departments of

medicine, surgery, or midwifery

The Council proceeded to consider the case of William

Stewart of Denon, near Manchester, registered in Ireland

May 19th, 1887, as M D. Mass Surg, 1887, R Univ. Irel,

who had been summoned to appear before the Council to

answer the following charge as formulated by the Council's

solicitor—

Complaints have been lodged with the Council by the Ashton under

Lyne and District Medical Society in relation to the Denon and District

Provident Dispensary by whom Dr Stewart is engaged as medical

officer and by whom an unequalled person named Burgess is engaged

or employed as his assistant The complaint is that Dr Stewart, asso-

ciated with this said unequalled person in the practice by him (Burgess)

of medicine and surgery and permit him to carry on medical practice

as if he were a duly qualified medical man

Mr H. Hyde solicitor, attended on behalf of the Ashton under

Lyne and District Medical Society in support of the

charge.—Dr Stewart appeared in answer to his summons,

together with his counsel, Mr H. Sharratt, and his

solicitor Mr J. Bond.

Mr FARRER, solicitor to the Council, having read the

charge

Mr Hyde opened the case on behalf of the complainants

He pointed out that the dispensary with which Dr Stewart

was connected issued a report in which Mr Burgess was

described as Dr Stewart's medical assistant and that there

of this dispensary connection added Mr Burgess to practice

on his own account, notwithstanding that Mr Burgess was

unqualified

Mr SHARRATT, on behalf of the accused, read the

declarations which had been made in answer to those put in

by the prosecution, contending that the whole of the so-

called evidence against Dr Stewart was only hearsay.

The information and complaint were lodged by the corner

for South West London and by the Medical Defence Union

Medical Register

General Medical Council permitted his name to be restored to the

Mr. Braxton Hicks, the coroner, and Dr. Bateman, the secretary of the Medical Defence Union, attended in support of the charges. Mr. Holland appeared for himself. The charges were read by Mr. Farrer.

Dr. BATEMAN, in the absence at the outset of Mr. Braxton Hicks, opened the case against Mr. Holland. He mentioned that the latter's name had been erased from the Medical Register in 1895, and he had given the undertaking referred to in the charge when he applied for restoration in the year following. The present proceedings had been instituted because of what occurred in connexion with an inquest held in January last.

Mr. BRAXTON HICKS continued the opening of the case and read certain depositions taken at the inquest referred to. He thought the Council would agree that he was justified in asking whether Mr. Holland's conduct was not unprofessional conduct. It was impossible for him to wink his eye at it and say that the accused was not covering an unqualified assistant. If Mr. Holland could not keep a practice of his own the Council should not allow him to cover an unqualified man. It was a danger to the public if this was to be allowed.

The depositions referred to and a business card were put in. The latter offered advice and medicine for 4d and midwifery attendance for 15s.

Mr. HOLLAND tendered himself as a witness on his own behalf.

The statement made by him in answer to the charges was read by Mr. MUIR MACKENZIE. In this it was stated that Mr. Blumenthal had a chemist's shop and wished a medical man to attend at it daily. If Mr. Blumenthal attended to any patients it was without his (Mr. Holland's) knowledge or consent. Mr. Blumenthal never did attend to a patient with his consent or connivance. There were other instances of chemist's shops in London where medical men attended daily. With reference to the charge as to advertising he did distribute some handbills, but he was not aware that the Council objected to the distribution of such advertisements on a man's first coming to a dispensary.

In answer to the PRESIDENT.

Mr. HOLLAND said that his statement was correct and he had nothing to add to it and no further observation to make.

Mr. BRAXTON HICKS and Dr. BATEMAN stated that they had no wish to ask Mr. Holland any questions. No member of the Council desired to put any questions.

Mr. Holland and strangers having by direction of the PRESIDENT withdrawn the Council deliberated on the case *in camera*.

On the readmission of the public the PRESIDENT intimated to Mr. Holland that the charges made against him had been proved to the satisfaction of the Council who now judged him to have been guilty of infamous conduct in a professional respect and directed the Registrar to erase his name from the Medical Register.

Mr. HOLLAND asked if he still could attend midwifery cases.

The PRESIDENT. I am sorry I cannot advise you.

Mr. HOLLAND. Where can I get advised?

The PRESIDENT. I am afraid I cannot give you any advice on the matter.

Mr. HOLLAND. Can I act as assistant to a medical man? I have the opportunity of becoming an assistant, and I want to know in what capacity I can act now that my name is erased from the Register?

The PRESIDENT. I have already said that I am not in a position to advise you.

The Case of William Henry Cossens.

On this case being called, and Mr. Cossens having appeared with his solicitor, it was agreed, on the motion of Dr. MOYAL, seconded by Dr. HERON WATSON, to proceed with its consideration *in camera*. When the public were readmitted.

The PRESIDENT announced that the Council had considered *in camera* the case of William Henry Cossens, of Derby street, Preston, Lancashire, registered in England on Oct. 22nd, 1886, as Lic. Soc. Apoth. Lond., 1885, who had been convicted of a misdemeanour at the Liverpool Assizes, Nov. 25th, 1898, and that, on the question put from the chair, it had been resolved that William Henry Cossens, having been proved to have been convicted of a misdemeanour, the Registrar be directed to erase his name from the Medical Register.

The Council adjourned.

SATURDAY, JUNE 3RD

The Council met again to-day, Sir WILLIAM TURNER presiding.

The Case of Henry Rowton

The Council proceeded to the consideration of this case which had been adjourned from the last session.

At the last session the Dental Committee reported the facts of the case as follows—viz. that Henry Rowton was registered in the Dentists' Register on Nov. 12th, 1878, as having been in practice before July 22nd, 1878, in conjunction with pharmacy, that his address was 109, Hall street, Dudley, that he was also registered in the Chemists' and Druggists' Register as having been in business before 1868, that on May 2nd, 1898, he gave and signed a certificate of death in the terms following: "This is to certify that Edward Fisher, aged three days, died on May 2nd, 1898, the cause of death debility from birth convulsions", that on July 23rd, 1898, Mr. Rowton having been asked by the solicitor to explain his conduct wrote the following letter: "I do not attend patients or pretend to be a medical man. The children were brought to my shop and I told them to get a note from the parish doctor or one from the dispensary, which I suppose they neglected doing. The so-called certificates were information for the Registrar, which he has often sent for", and that a letter was read from Mr. Rowton's solicitor stating that his client undertook never again to issue any documents which could be considered to be medical certificates or to attend any patients as a medical practitioner. The Dental Committee added a recommendation that no further action be taken in the matter and the decision of the Council was to adjourn the case until the present session.

Mr. FARRER informed the Council that both Mr. Rowton and Mr. J. D. Price, who was the complainant, had received notice that the case would be considered to-day, but no answer had been received from either of them.

After the Council had deliberated *in camera* the PRESIDENT announced that they had come to the following decision in the case—viz. That the Council, taking into consideration the undertaking made on behalf of Mr. Henry Rowton that he will never again issue any documents which can be considered to be medical certificates or to attend any patients as a medical practitioner, resolves to proceed no further in regard to the charge found to be proved against him.

The Case of Clement Maguire Kershaw

The Council then considered the case of Clement Maguire Kershaw in regard to whom the Dental Committee had found the following facts—viz. The case of Clement Maguire Kershaw having been referred to them to ascertain the facts in regard to such case the Dental Committee find the facts, either admitted or proved, to be as follows—

1. Clement Maguire Kershaw was registered in the Dentists' Register on July 22nd, 1891, under the 37th Section of the Dentists' Act, without any diploma. His registered address is at Newtown, in North Wales. 2. The said Mr. Kershaw has a dental surgery at Newtown. He has also a branch practice which is carried on at Llanidloes, which is some miles distant from Newtown. 3. Mr. Kershaw formerly had branch practices at Welshpool and Llanfair, but these had been given up some time before the date of the complaint, made against him. 4. Mr. Kershaw has, had for five and a half years, and has now in his employment at a salary, an unregistered and unqualified person named Victor Neighbour. From time to time this unqualified person has been permitted by Mr. Kershaw to perform the operations of extracting teeth for patients and filling the teeth of patients with plastic fillings in the absence of Mr. Kershaw. In one case the said Victor Neighbour performed a dental operation on a patient under chloroform in the absence of Mr. Kershaw. It being stated that Mr. Kershaw was ill at the time. The chloroform was not administered by Victor Neighbour. 5. The said Victor Neighbour has been permitted by Mr. Kershaw to see patients independently of him and to do more than fell within the province of a mechanical assistant.

The PRESIDENT announced that the Registrar had received a letter from Mr. Maurice, the complainant in the case, saying that he was not going to appear that day.

Mr. MUIR MACKENZIE read the report of the Dental Committee given above and Section 15 of the Dentists' Act of 1878, bearing on the case. The section says: "The General Council shall, for the purpose of exercising in any case the powers of erasing from and of restoring to the Dentists' Register the name of a person or an entry, ascertain the facts of such case by a committee of their own body not exceeding five in number, of whom the quorum shall be not less than three, and a report of the committee shall be conclusive as to the facts for the purpose of the exercise of the said powers by the General Council."

Mr. R. A. GERRARD, barrister, addressing the Council on behalf of Mr. Kershaw, said he had no intention to dispute

As regards the general principle of the Bill it is undoubtedly of a very stringent character. If passed into law its effect would be to make it a criminal offence for a person whose name had been removed from the Medical Register for misconduct to practise medicine or surgery in any way. The creation of such an offence would introduce an altogether new principle in the legislation which is embodied in the Medical Acts and would probably arouse very considerable opposition in Parliament. Expressing my own opinion, I could not advise the General Medical Council to support such a measure without very careful consideration.

As regards the details of the Bill, the points upon which I wish to observe are the following:—

The 3rd Clause provides that on a summary conviction the offender is to pay to the General Medical Council a sum not exceeding £20. The words of the Clause thus differ from those of Section 40 of the Medical Act, 1858, and seem to me open to objection on that ground. Next there is no reference to midwifery in the 3rd Clause of the Bill. This seems to me to be open to objection.

Lastly as regards the 4th Clause, it does not in my opinion adequately meet the difficulty which has arisen with regard to the payment to the General Medical Council of penalties inflicted under the Medical Acts. The difficulty which has arisen is that the metropolitan authorities contend that by virtue of the stringent terms of the Police Act, 1839, which provides that penalties imposed by any future Act of Parliament, when recovered in the metropolis, are to be paid to the Receiver of Police, that official is entitled to all the penalties recovered under the 40th Section of the Medical Act, 1858 in the metropolitan police courts. The clause in the proposed Bill is not framed, I think in terms which would displace the contention of the metropolitan authorities, if that contention is a sound one.

On the whole therefore, I do not feel that I can advise the General Medical Council that the proposed Bill is one which deserves the Council's support. (Signed) M. MUIR MACKENZIE.

4, Temple-gardens E.O., May 11th, 1899

Dr MACALISTER moved that the communication from the Privy Council, along with the enclosure and the report on the proposed Bill by Mr Muir Mackenzie, be entered on the minutes

Mr BRYANT seconded the motion

The motion was agreed to

Mr BRUDENELL CARTER We are not asked by the Government to give any opinion on this matter

The PRESIDENT No, it is only to supply us with information on the subject

Mr BRYANT asked whether it would not be well that the Council should have some information as to the nature of the society asking for the Council's action

The PRESIDENT The association referred to in this case addressed the Privy Council and the Privy Council sent us their communication. The association does not come directly to us

Mr BROWN I think we should give some kind of reply to the Privy Council

The PRESIDENT We are not asked to

Mr BROWN said that he must express regret that the Executive Committee had not asked the Council to support such a measure as the one included in the communication, because he believed the proposed Bill contained clauses which the Council very much desired. He should have been much better pleased if Mr Muir Mackenzie, instead of pointing out difficulties, had told the Council how to avoid the difficulties that were in the way. He should like to have some guidance in this matter. Although Mr Muir Mackenzie did not offer them any guidance he was rather astonished to find that in the interim report of the President clauses were submitted for the recovery of fines in medical cases in the metropolitan police courts

Dr CHURCH rose to a point of order. He said there was no motion before the Council and Mr Brown was introducing a subject which was not before them

The PRESIDENT agreed that there was no motion before the Council

Mr BROWN suggested that the matter should go to the Executive Committee.

The PRESIDENT No

The subject then dropped.

The Apothecaries' Hall of Ireland

Sir DYCE DUCKWORTH, chairman of the Examination Committee, presented reports on the inspection of examinations of the Apothecaries' Hall, Dublin, held in October, 1898, and in January and April of the present year. After reading portions thereof he moved that the reports be received and entered on the minutes

Mr BRYANT seconded the motion

Mr TICHBORNE said that he objected to the reports going on the minutes and he moved the adjournment of the debate

This motion was agreed to

The Council adjourned till Monday

MONDAY, JUNE 5TH

The Council met again to-day, Sir WILLIAM TURNER presiding

The Examinations of the Apothecaries' Hall of Ireland

The first business was the consideration of the motion brought forward by Sir DYCE DUCKWORTH on Saturday —

That the reports of the Examination Committee on the inspection of the examinations of the Apothecaries' Hall, Dublin be received and entered in the minutes.

Mr TICHBORNE, the representative of the Hall, said he desired to object to this motion because he took exception both to the tone of the reports and to some of the matter they contained. The tone of the Examination Committee was antagonistic to this body and it appeared to him that all through these reports they were trying to make out a case against it. He submitted that the observations made by the committee were in several instances not borne out by the reports of the visitors, inspectors, and examiners, and he concluded by moving as a rider to the motion —

That certain expressions and passages be omitted from the reports of the Examination Committee.

Dr BRUCE seconded this proposal

Sir DYCE DUCKWORTH denied that the committee had done more than discharge the somewhat difficult duty imposed upon them in connexion with the examinations of this body which in a sense was under the tutelage of the General Medical Council and he insisted that justification for everything said by the committee in their reports would be found in the reports of the visitors, inspectors, and examiners. Exception had been taken to the use of the word "solitary" before the word "candidate," but he considered it necessary to accentuate the fact that all this heavy machinery of examination was brought into play to examine a single candidate. It was no small matter this for the Council because in connexion with the examinations of this body during the last 15 months they had spent no less than £307 10s 8d. As long as he was chairman of the committee he would take care that they did their duty without fear or favour and reported to the Council what they considered it their duty to report in the circumstances of the case

Mr HORSLEY said he desired to support the Examination Committee. He was sure the profession did not know that because the Apothecaries' Hall of Dublin wished to hold these examinations they were being taxed to this extent.

Dr BRUCE said that whatever the cost might be this Council was bound to carry out the law

The motion of Mr Tichborne was put to the Council in three sections and each section was rejected by a large majority

Sir CHRISTOPHER NIXON said he would like to know whether the Council were going to continue this large expenditure in view of the small return obtained from it. He quite agreed that the law must be carried out, but as practical men they must look for some result for the money they expended

The PRESIDENT said that this was a matter which really was not before the Council

Sir CHRISTOPHER NIXON intimated that he would give notice of a motion on the subject.

The reports were then formally received and ordered to be entered in the minutes

The Standard of the Preliminary Examinations

Sir JOHN BATTY TUBE presented the following interim report by the Education Committee on the proposal to raise the minimum requirements of the Council as regards preliminary examinations to the level of the senior and higher grade examinations

On Nov 29th, 1898, the following motion was agreed to by the Council

That the Education Committee be requested to consider and report to the Council during the next session as to the earliest date at which, in their opinion it will be practicable to raise the minimum requirements of the Council as regards preliminary examinations to the standard of the senior and higher grade examinations at present recognised.

The committee, being fully aware of the complexity of the subject of the reference, deemed it advisable to obtain the opinions held regarding it by various educational authorities and to lay them before the Council

The following letter was accordingly sent to the bodies and persons connected with general and medical education whose names are contained in the Appendix Section I —

Edinburgh 20 Charlotte-square Dec. 27th, 1898.

SIR, — The General Council of Medical Education and Registration is

opinion as to those who had to be practicable at an early date, without going into a detailed analysis of the subject was the heads of schools and colleges, and the heads of purely medical bodies—that was to say, bodies which did not deal with general and medical education jointly. It was equally interesting to note that bodies which dealt conjointly with general and medical education sounded notes of warning in the case of most of the universities doubt was thrown upon the practicality of immediate action, at any rate, they advised caution in action. He wished specially to draw attention to the replies received from the universities of Scotland, inasmuch as these bodies had within a few years had the experience of a sudden raising of the standard of preliminary education and they had given the results of that experience. An important point was the raising of the age and the consequent reduction in the number of medical students. It was held by some of the bodies that the general tone and high standard of medical education existing in Great Britain and Ireland at this moment might drop if the number of students were reduced. Another point brought out by the replies was that the relative value of certain of the preliminary examinations accepted by the Council was not well defined and he might say that during the past months the committee had been endeavouring to satisfy themselves upon this point. They had made application to various examining bodies to allow them access to the answers of candidates. They had applied to the Oxford and Cambridge Schools Examination Board, the Education Department for Scotland, the Scottish Educational Institute, and the Council Board of the Irish Colleges. All these bodies had given them access to papers. The papers they asked for were 20 or 25 specimen papers of the lowest mark candidates—the men who in students' language just managed to scrape through. Members of the committee had examined these papers and formed their own individual opinion about their relative merits. No one could doubt that this was the only way to arrive at any estimate of the relative value of the examinations. But the committee felt that the inspection of papers should be undertaken by authorities in general education. However willing the Council might be to accept the opinion of members of the Education Committee, these members felt that too much responsibility would be thrown upon them if they were asked to undertake this duty. The committee felt that they could not come to a conclusion upon the general question without some expert assistance as to the relative value of the junior examinations and therefore other matters in connection with which expert assistance would be of the very greatest use. The plan of action would, it appeared to him, though it had not been actually recommended by the committee, be that they should appoint three men one for each division of the kingdom who as far as possible were unconnected with any interest involved and that to them should be submitted the requirements of the examinations of the various bodies in order that they should see whether they came within the requirements of this Council, and that they should apply again for the inspection of papers from the various bodies and forward the papers to the experts. It might be advisable that the experts should hold conference with the Education Committee, but whether they did or did not they would frame a report upon which the Education Committee could form a report to this Council. In this way he hoped the committee would be able in November to suggest a scheme by which a system of gradual raising of the junior examinations could be established such as would not leave much to be desired in 1905. But the committee felt that until they were supported by the opinion of such experts as had taken a definite opinion as to the relative value of many of the examinations—it would be extremely difficult for them to issue a satisfactory report to the Council. But backed up by such an opinion he believed they would be able to submit a scheme in November which would meet with very general acceptance.

Dr MACALISTER formally seconded the motion.

THE PRESIDENT said that he would venture to point out that this was only an interim report and to suggest that the various communications received by the Education Committee but limit themselves to the two recommendations one, that the period of reference should be extended, and

continuous of raising considerably the standard of general education in Arts which is required of students intending to prepare themselves for the medical profession. Since the 1st day of January 1901 it provides for the purpose of the registration of such students at their entrance upon the professional course to accept no certificate of examination in the educational subjects prescribed by the Council of the University which is given for a lower standard of attainment than that required for the junior local examinations of the English and Scottish Universities and the equivalent junior examination held in Ireland. The Council and the Education Committee are, however, anxious to introduce, as soon as it is deemed practicable, a still higher standard of requirement represented by the higher grade examinations of several of the Departments, and the senior grade examination of the Intermediate Education Board of Ireland.

The Education Committee has accordingly been requested by the Council to instruct inquiries in order to ascertain the earliest date at which such advance may be made having in view the desirability on the one hand of maintaining the educational status of medical students, and on the other of avoiding such a diminution of the supply of candidates for the profession as would be detrimental to the public interest.

In the belief that the knowledge and experience at your command will enable you to give the committee assistance in determining the questions now under consideration, I beg leave on the behalf to ask you to favour me with an early reply to the following inquiries and to say that your reply, together with any communications on the general subject which you may see fit to make, will have the careful attention of the committee and of the General Council.

1. Is it practicable within the next few years to require that all intending students of medicine shall pass an examination equivalent in character and standard to the senior local and higher grade examinations?

2. If it is practicable, what is the earliest date at which the higher grade examinations would probably be precluded from entering upon a course of medical study (say at the age of 18 years) if the junior examinations to be presented would amount (say in 1900) to be accepted by the Council for the purpose of registration?

3. What proportion of students would probably be precluded from entering upon a course of medical study (say at the age of 18 years) if the junior examinations to be presented would amount (say in 1900) to be accepted by the Council for the purpose of registration?

4. Has the Education Committee any regulations regarding the registration of medical students and a copy of a table showing the results of preliminary examinations in 1891 compiled by the Registrar of the Council from such returns as have, in response to the Council's request, been supplied by the examining bodies. I am, Sir, your obedient servant,

JOHN BARRY, Esq.,
Chairman of Education Committee of the
General Medical Council.

To
The Committee

The committee submit the reply already furnished to the references to the report in May 1899 as they expect to receive further communications in the request contained in the reference to the evidence before the committee and as they could not possibly collate the evidence before the committee at that time. The committee believe that it is of the greatest importance to give the Council an opportunity to study the various communications now submitted. Without committing themselves to any expression of opinion the committee beg to indicate to the Council that, considering the importance and important interests to be considered, the preparation of the report demands considerable time and attention and they accordingly trust that the Council will consent to extend the period of their reference.

The committee have come to the conclusion that in order to deal effectively with the questions raised by the communications can be obtained in this interim report they must ask the Council to provide them with the means of obtaining expert assistance. They therefore disposed for this purpose.

The Council agreed to receive the report and have it entered in the minutes.

SIR JOHN BARRY, Esq.,
the Education Committee during the last six months had been endeavouring to carry out the reference made to them in November of last year. It was suggested that it would be persons closely connected with general and medical education, and accordingly a circular letter was issued to a certain number of bodies they had received 44 answers. To this letter they had not answered and he could not help expressing some surprise at the omission of certain of these bodies concerned and the Council were under considerable obligation to them for the care and attention which they had given to the subject. The inquiries of the committee showed that the whole question was much more complex and difficult than appeared, to certain members of the Council six months ago. A study of the answers received brought out the fact that there was a very wide divergence of opinion on the proposal made. On the one hand they had opinions that it was impracticable to raise the standard to the level of the senior and higher grade examinations in 1905 or even earlier while on the other they had opinions that it was absolutely impracticable at any rate for many years to come between these two extremes they had various shades of

the other that the committee should be provided for one year with a sum of £100 to get the expert assistance suggested.

Mr. BRYANT said that as chairman of the Finance Committee he could see no objection to this very modest request on the part of the Education Committee.

The two recommendations in the form suggested by the President were put to the Council and at once adopted.

The Midwives Bill

Sir RICHARD THORNE, as chairman of the committee, read the following report by the Midwives Bill Conference Committee on the Midwives Bill, 1899—

In accordance with the resolution of the Council of Nov. 29th, 1898, "That the Midwives Bill Conference Committee be re-appointed (with the addition of Mr. Horsley) for the purpose of watching any legislation that may be proposed on the subject in the next session of Parliament, your committee have considered A Bill to Promote the Better Training of Women as Midwives and to Regulate their Practice, 1899," which has been read a first time in Parliament, and they now beg leave to report as follows. A copy of the text of the Bill is hereto appended.

1. With reference to Clause 2 of the Bill they would recall the fact that in a report of the Council April 6th, 1893, which was directed to be forwarded to the Lord President of the Council, the Council laid it down "that the term 'midwife' should be defined as meaning a woman who undertakes for gain to attend cases of natural labour and who is not registered under the Medical Acts. Clause 2 of the Bill of 1899 defines a midwife simply as a woman who undertakes for gain to attend women in childbirth.

Your committee hold it to be of fundamental importance that the words 'natural labour' should be retained in the definition and they strongly urge this point for the following amongst other reasons—

If the word 'childbirth' is used without limitation it may well be held to confer on women not registered under the Medical Acts, a statutory right to attend for gain cases of abnormality or disease in connexion with parturition. This is not only contrary to the public interest, but is inconsistent with Section 32 of the Medical Act, 1853, and of Section 6 of the Act of 1836.

Your committee hold, strongly that a point which is of such vital importance should be expressly embodied in the statute and should not be left to be dealt with under rules which may be varied from time to time.

As regards the meaning of 'natural labour' your committee are of opinion that the rules to be drawn up by the Central Midwives Board under Clause 5 (3) I (d) of the Bill can be fully relied on to deal with any difficulties such as, it is alleged might arise on this point. It would be easy for example, to specify the conditions indicating difficulty, abnormality, danger, or disease under which qualified medical assistance should forthwith be sought.

2. As regards the matter dealt with in Clause 3 (2) of the Bill your committee are of opinion that the Bill should contain a provision making it penal for a licensed midwife to employ as her substitute in attending for gain on a case of labour any person not licensed under the Act.

Sub-clause (4) of this clause should, in their opinion, be extended so as to prohibit the granting by a licensed midwife of any certificate relating to a death or stillbirth.

3. On Clause 4 your committee are of opinion that the requirement as to evidence of good character should apply to all applicants for 'licences' and also that the clause should be amended so as to make all certificates purporting to be evidence of training and skill in midwifery subject to the approval of the Central Midwives Board.

4. With regard to Clause 5 (1) your committee resolved to disapprove of the proposed constitution of the Central Midwives Board, on the grounds that it should be more representative in character and should include registered medical practitioners who are familiar with the conditions of midwifery practice in local districts throughout England and Wales.

As to sub-clause (2) of this clause they would further state that it is their opinion that all the members of the Central Midwives Board should be registered medical practitioners.

With regard to sub-clause (3) they would observe on (a) that they are of opinion that it should be made clear that the rules passed by the Central Midwives Board are not to be valid, unless and until they have been approved by the General Medical Council and on (b) that, in their opinion the paragraph should run as follows: "regulating the course of training and the conduct of examinations" to be required for a 'licence'.

5. In Clause 7 of the Bill your committee are of opinion that the term "qualifications" should be avoided as being likely to lead to misapprehension and that it should be replaced by the term "conditions," which is used in Clause 6 (3) I (a).

6. On Clause 9 the committee would express the opinion that the local sanitary authority, which is primarily concerned with questions affecting the prevention of disease, including puerperal fever, should take part in the local administration of any Act relating to midwives. Modification of the Bill in this sense would involve corresponding modification of the financial and other clauses of the Bill.

7. At this point they would also call attention to the imperative necessity of making provision for qualified medical assistance in every case attended by a midwife, which presents symptoms of difficulty, abnormality, danger or disease on the part of the mother or of the new born child. As regards this matter they would call attention to report of the Council of April 6th, 1893, paragraph (10), and to the concluding paragraph of the report by the committee appointed by the Council to confer with delegates from the Midwives Bill Committee, Nov. 22nd, 1898.

8. With regard to the concluding paragraph of the Bill your committee are of opinion that a small fee should be charged on each occasion of the annual renewal of the 'certificate.'

9. They are further of opinion that the misdemeanour referred to in Clause 11 (a) of the Bill should relate to both the 'licence' and the 'certificate.'

10. On Clause 12 the committee would observe that in their opinion the misdemeanour as to falsification should include any person and should not be limited to the person appointed to keep the roll.

11. On the Bill generally your committee would further observe:—

(a) That the term 'licence' should, throughout be restricted to the permission granted by the local supervising authority to practise in a given area, and that the document, granted by the Central Midwives Board, should be termed a certificate entitling the possessor, to be placed on the Midwives Roll and thereby testifying to her competence to receive a local 'licence.' This change will involve certain consequential modifications in many of the clauses of the Bill.

(b) That they assume that before any Bill regulating the training and practice of midwives is passed, into law provision will be made by Parliament for covering both the general and special expenses which the Council and any committee appointed by them will have to incur in the performance of any duties that may be imposed on them under that law.

The committee accordingly recommend: That the Council inform the Lord President of the Privy Council that they are unable to approve the Bill unless it is recast in accordance with the suggestions made in this report.

The report, on the motion of Sir RICHARD THORNE, seconded by Dr MACALISTER, was received and entered on the minutes.

In answer to the PRESIDENT,

Sir RICHARD THORNE said that he did not intend to move the adoption of the committee's recommendation. He could not do so for this reason, that there was a very important clause in the report in regard to which when it was put before the committee he was in the minority.

Mr. HORSLEY said that if it was to put the Council in order he should be very happy to move the adoption of the report because he felt most strongly that it should go to the Privy Council.

Sir CHRISTOPHER NIXON, another member of the committee, agreed to second the motion for the adoption of the report.

Sir RICHARD THORNE did not think any advantage would accrue from the representation of medical practitioners for local districts and he was distinctly of opinion that any central midwives board that might be formed should have in it something of the lay element.

Dr MACALISTER, as another member of the committee who was in the minority in which the chairman had found himself, contended that if the Council adopted Section 4 of the report which was now before them they would be going beyond the Council's previous policy on this question, and if they spoke to the Privy Council in the sense of the report they would minimise their influence with the Council.

Mr. BRUDENELL CARTER was inclined to think that if the Bill passed one of its early effects in many localities would be to prevent women now practising continuing to do so and it would be quite sure to excite in many localities certain feelings of sympathy—certain feelings that the women were being subjected to hardship. Under such circumstances he could not help feeling that there should be a non medical element on the Midwives Board. The Government might follow the example in the Medical Act in constituting any such central board for midwives as that proposed. At the same time he thought that it would be unwise for the Council to adopt the report of the majority of the committee.

Dr LOMBS ATTHILL said that he had considered this report with very great care and as one who had had midwives under his care for the greater part of his professional life he wished to say that he thought the report was very satisfactory. He was thoroughly in accord with Mr. Carter and other speakers that there should be a non medical element on any central board which might be formed. He also thought that this proposed board was very much superior to that in the other Bill, which proposed that there should be a number of ladies and the representatives of certain bodies which had no characters of incorporation. The smallness of the proposed board was a recommendation. He thought it would be a very great mistake for the General Medical Council to disapprove of Clause 5 of the Bill, for he feared that if the board was to be entirely a medical board it would be looked upon as a partisan board.

An endeavour was made to 'arrive' at an 'understand' ing. It was moved by Mr. HORSLEY and seconded by Sir CHRISTOPHER NIXON—

That the report of the Midwives Bill Conference Committee on the Midwives Bill, 1899, be adopted and that the Council do inform the Lord President of the Privy Council that they are unable to approve the Bill unless it is recast in accordance with the suggestion made in this report.

As an amendment it was proposed by Sir RICHARD THORNE and seconded by Dr MACALISTER—

That the Council withhold its approval from the first two paragraphs of Clause 4 of the report and that the communication to the Lord President of the Privy Council be modified accordingly.

Mr. HOBART wished to speak with reference to this amendment. He did not object to the introduction of the lay element but he thought that if the body was to be a small society there would be danger in introducing the lay element in the clause objected to had been carried by a majority in the Council. On a division the amendment was carried by 17 votes to 10, and when put as a substantive motion by 16 votes to 10. Dr. MACALISTER moved that the report as amended by the resolution of the first two paragraphs of Section 4 of the report should be passed unanimously agreed to.

[The proposal was unanimously agreed to.]

The following further report from the Midwives Bill Conference Committee was read by Mr. ALLEN, the Registrar —

(a) The Midwives Bill Committee have had under consideration a memorandum, &c. by the British Medical Association on the Midwives Bill referred to them by the President of the Council and they beg to suggest that the British Medical Association be thanked for their communication and enclosures and that they be informed that the Council, in dealing the report on the Midwives Bill which they have submitted to the present session of the Council, have had regard to the principal matters embodied in the memorandum and that Bill of the Association, and that the Association will find that the committee to the Council will show that the consideration is given to the memorial has been considered a report of March 6th, 1899, forwarded by the Royal College of Surgeons of England and submitted to the President of the Council.

(b) The committee report that the matters referred to in the report of the Council have received their consideration and that they believe the report which they have presented to the Council during the present session contains evidence that they have felt it their duty to direct the attention of the Council to the majority of the points referred to in the report of the College.

Sir RICHARD THORNTON said that the foregoing was the answer that it was proposed to send to the memorialists. He moved that the report be received, entered on the minutes, and adopted.

Dr. MACALISTER seconded and the motion was agreed to.

Diploma in Public Health

Sir RICHARD THORNTON, on behalf of the Public Health Committee, submitted a report on the regulations for the Diploma in Public Health of the University of St. Andrews, which was as follows, was received, adopted, and entered on the minutes —

Resolved that the regulations for the Diploma in Public Health forwarded to the Council by the University of St. Andrews be laid to report as follows —

1. They would point out that whereas the rules adopted by the Council on June 9th 1898, require that a period of not less than 12 months in medicine, surgery, and midwifery, and the admission of the candidate to any part of any examination for the diploma, is by no means clear that this condition is required under the regulations for the University of St. Andrews.

Note 1 requires that this interval of 12 months shall elapse before entering upon the examination for this Diploma. There are, however, no examinations, and whereas under Rule 11 a candidate need not be followed until the candidate proceeds to the second examination for the diploma.

The working of these two rules in relation to the second examination of the Council is to say the least, ambiguous, and in view of the fact that the candidate is definitely informed that he can enter upon one part of the examination before he has even commenced the second of the two parts of the diploma it should be made clear in Regulation No. 1, that no candidate can present himself for any part of the examination until a year has elapsed since the attainment of a respectable qualification under the Medical Act.

2. Whilst admitting that the Regulation No. 1V which deals with the subjects of the examination is satisfactory when read together with the appended to the Regulation, it is a matter of opinion that the subjects are somewhat played and overdone, and it is to be regretted that this regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

3. It is stated in Regulation No. IV that the second examination is to be held on or practical part of the diploma examination, to the subject of the diploma, to which promises is given in the rule of the Council.

4. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

5. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

6. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

7. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

8. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

9. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

10. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

11. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

12. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

13. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

14. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

15. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

16. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

17. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

18. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

19. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

20. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

21. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

22. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

23. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

24. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

25. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

26. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

27. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

28. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

29. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

30. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

31. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

32. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

33. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

34. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

35. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

36. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

37. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

38. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

39. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

40. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

41. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

42. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

43. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

44. It is to be regretted that the regulation contains no reference to the examination, to the subject of the diploma, to which promises is given in the rule of the Council.

[illegible]

The Registrar. More than a month ago Mr Horsley said it is quite obvious that members have not had time to read it. The President. But the report was circulated only a month ago.

Mr Horsley. At any rate, I state that as a fact. Proceeding, Mr Horsley said that the next point was that the proposition by the committee took the Council almost beyond their province. The work which the Council had to do was laid down by the Medical Act and the Council had no permission to dictate to the profession what was to be the duty of it. They might suggest and if this was to be a suggestion only then there was not so much to object to in it. Still, the Council were that it behooved them not to agree to any motion which would impair the dignity or curtail the proper functions of the Council. Now, if they were to make a suggestion of the kind in question to the profession the profession would naturally ask if they had examined into the circumstances in which they proposed to enter into conference. Would the wage limit be discussed? On behalf of the friendly societies it had been stated that it would be impossible for them to discuss the wage limit. Why, then, should the profession go into this with their hands tied? The matter altogether was a very difficult one and would require much further consideration from several points of view. In the meantime his opinion was that this board of conciliation could have no useful outlet for its work and he wished the Council if they went to a vote to negate the proposal.

Mr Brown said that while he agreed generally with all that had fallen from Mr Horsley, he at the same time thought that if a board of conciliation were formed upon which the members of the medical profession were largely represented and could confer with the managers of the friendly societies it might be possible to bring about a *modus vivendi* that would prevent the necessity of the intervention of the General Medical Council. The recommendation in operation might prove to be a thoroughgoing one on the troubled waters. He thought the proposal deserved a trial and if it were found that it did not answer it could be dropped at any time.

Mr BUNDELL. CARRER was of the opinion that the adoption of the recommendation might do a great deal of good. The proposed board could not do any harm. That Council had no power to prevent any man from selling his skill or services on any terms that might seem good to him, but he thought the Council might say to the profession that the best thing they could do would be to go into conference with the friendly societies and thrash out with them in a friendly way their respective difficulties.

Mr BRIDGES. His view was that nothing but good could result from the deliberations of a conciliation board. The society represented at the conference numbered 33, and a capital of £23,000,000 sterling. Since that conference he had the opportunity of meeting the Chief Registrar of Friendly Societies who regarded a conference between the representatives of friendly societies and of the medical profession very hopefully and with evident satisfaction, and he trusted that the General Medical Council would do their best in support of the proposal.

Dr LEECH supported the recommendation because he was of opinion that a board of conciliation such as was proposed would do good to the medical profession, but a great deal more good to the friendly societies. It would be a great disappointment if the Council did not accept this recommendation of the proposed board.

Mr TAYLOR wished to tell the Council that he was greatly struck by the tone of the gentlemen from the friendly societies who met the committee of the Council by their statesmanlike policy and their generous appreciation of the work of the medical profession, and also by their real desire to do what was fair as between their own associations and to a friendly termination of the medical profession so as to bring all matters in dispute to a friendly termination.

Mr RICHARD THORNE thought that he ought to oppose the formation of this conciliation board until he knew how it was going to be constituted. Seeing that the Council had opinion that having regard to their statutory responsibilities no member of the Council should take any part in the constitution of the proposed board.

Dr LEECH. I am sorry to hear that the Council should take any part in the constitution of the proposed board. It is in my opinion a very important matter and I am sure that the Council will do its duty in this regard.

Dr LEECH. I am sorry to hear that the Council should take any part in the constitution of the proposed board. It is in my opinion a very important matter and I am sure that the Council will do its duty in this regard.

Dr McVAIL could not see in what way the opinion of the profession on this subject could be ascertained. How were they to obtain the five or six medical representatives? There was no question that if the General Medical Council proposed them the medical profession would repudiate them. Dr Brown pointed out that if the General Medical Council could not go the length of appointing the medical representatives to a conciliation board, if they agreed to the principle of such a board they would be taking a large step forward. He agreed with Dr Glover that there was a great disposition to come to terms.

Sir JAMES DUNCANSTON said that whatever vote the Council should give he would regard it as only an academic vote. He hoped that the Council would take no active part whatever in the matter.

After some remarks by Sir CHRISTOPHER NIXON, The President said that the last speaker wished to dissociate himself from the preceding proceedings as something outside the powers of the Council as laid down by Acts of Parliament, but he wished to remind members that it was not the Council that raised this question, for the question was raised by certain members of the profession who were sent to the Council memorials and practically asked them to adjudicate those members of the profession who acted in connection with these associations to be guilty of infamous conduct in a professional respect. It was only right that the Council should endeavour to arrive at such a conclusion as would bring the friendly societies and the medical profession into harmonious action. The committee had done their best to accomplish that and he must say that he would have been led to the opposition to the recommendation of the committee if they had not heard any alternative proposal. He, however, had not heard a single argument against the committee's recommendation which had been convincing to him. All that the Council was now asked to do was to agree to the principle of the formation of a board of conciliation. If they so agreed, that would go out to the profession. The Council was not at this time asked to determine who were to be the medical representatives on the board. That was something which was not proposed at present. They might lead in the matter, but they must remember that they could not drive the friendly societies who were certainly very powerful institutions—powerful numerically, and in connection with the electorate, and in the influence which they could exercise at elections. And if the Council could by the adoption of the principle of the proposed conciliation board bring the friendly societies into harmonious cooperation with the medical profession he felt sure that the Council should have done a great act at this meeting.

Mr HORSLEY pointed out that he had offered a practical solution of the difficulty of the moment. He had asked Dr Glover to postpone this matter in order that the members of the General Medical Council who were not perfectly familiar with the matter should have an opportunity to consider it. The President. I do not consider that a practical proposal should be added to Dr Glover's motion as a proviso in the suggested that the principle of Sir Richard Thorne's under-bridge motion, but objection being taken, Dr MACDONALD thought for a time that the two might be combined in a proposal ought to be put to the vote. The President proposed a conversation ensued as to how this and Dr Glover of the proposed conciliation board.

Some conversation ensued as to how this and Dr Glover of the proposed conciliation board. The President proposed a conversation ensued as to how this and Dr Glover of the proposed conciliation board.

That having regard to the statutory responsibilities which devolve on the General Medical Council it was very inexpedient that any member of the Council should take part either in the constitution or decisions of the proposed conciliation board.

Some conversation ensued as to how this and Dr Glover of the proposed conciliation board. The President proposed a conversation ensued as to how this and Dr Glover of the proposed conciliation board.

The names of those who voted for the motion and those who did not vote were as follows —

For (20) Dr MacAlister, Mr Bryant, Sir Dyce Duckworth, Dr Pettigrew, Dr Church, Mr Tomes, Dr Heron Watson, Sir William Gairdner, Mr Brown, Mr Tichborne, Dr Glover, Mr Teale, Dr Bennett, Dr Phillipson, Dr Reid, Dr Cameron, Dr Leech, Dr Bruce, Mr Carter, and Sir John Tuke

Did not vote (eight) The President, Dr Atthill, Sir Richard Thorne, Dr McVail, Sir O. Nixon, Sir William Thomson, Sir Philip Smyly, and Mr Horsley

Absent (two) Dr Pye Smith and Dr Little

The discussion of the remainder of the report was postponed till Tuesday's meeting

The Council adjourned

TUESDAY, JUNE 6TH

The Council resumed work to-day, Sir WILLIAM TURNER presiding

Medical Aid Associations

The Council proceeded with the discussion of the report of the Medical Aid Associations Committee

The PRESIDENT said that he had called the attention of Dr Glover (the chairman of the committee) to the fact that his motion was in the position of what Sir Dyce Duckworth had called a pious opinion and that he had not suggested any means of taking action upon that opinion. He believed that Dr Glover had now a further motion to propose.

Dr GLOVER said that he proposed to move that a copy of the resolution passed yesterday be forwarded by the chairman of the committee to the various bodies and persons who had memorialised the Council on this subject.

Dr MACALISTER suggested that it should also be sent to the friendly societies and in the first place to the executive body of the great conference of the friendly societies.

Dr GLOVER expressed his assent to this suggestion.

Sir RICHARD THORNE asked whether there was any precedent for a chairman of a committee doing an act of this sort on behalf of the Council.

The PRESIDENT replied that no precedent occurred to him.

As the result of some further discussion it was agreed to hold this particular matter over till to-morrow in order that a resolution might be put into form.

Dr GLOVER then moved the adoption of the second recommendation of the committee —

That the Council strongly disapprove of medical practitioners associating themselves with medical aid associations in which touting and advertising for the purpose of procuring patients are practised.

He explained that in the first part of the report the committee dealt with the friendly societies, while in the second part they dealt with a different class of medical aid associations—namely, those which for the most part were promoted by commercial companies, generally of the insurance order, and who tagged on to the insurance business a medical aid department. The method by which these companies worked was essentially one of touting and advertising in a very marked degree. As a rule the friendly societies did not canvass, but these companies did business by going from door to door. Dr Glover then read to the Council a number of documents which he had received from various quarters which illustrated the methods of touting and advertising pursued by the companies and concluded by recommending the motion to the Council as containing a moderate and practical proposal.

Dr BRUCE formally seconded the motion.

Mr BROWN who had on the programme a notice of motion to this effect—

That this Council regards it as unprofessional to hold the appointment of medical officer to any society established for the purpose of providing medical aid to its members whose agents systematically canvass for members from door to door—

said that in his opinion the motion proposed by Dr Glover was not strong enough. He thought the action of the Council would have more effect if they declared that this conduct was "unprofessional." He spoke with some knowledge of these associations, for in the first year of his practice he was induced by an agent of one of them to allow his name to appear on the list of its medical officers. The district was a working and middle class district in the north of London and the agent pointed out the advantage it was to the poor to get good medical advice at a merely nominal figure. He was a young and somewhat enthusiastic surgeon then and he accepted the appointment. But what did he find? Why, in a few weeks he—

and among his own patients asking them to join "Dr Brown's club at a penny per week." He at once took steps to dissociate himself from the society and never again had he had anything to do with such an organisation. In this matter they ought to protect the profession and they ought to protect the public. The medical officers were called upon to attend patients in such numbers and at such fees that it was perfectly impossible for them to do justice to the patients and the public undoubtedly suffered in consequence. There were, of course, clubs and clubs. The general practitioner had nothing whatever to say against the ordinary friendly society composed exclusively of working men who paid such a fee as medical men throughout the country generally thought fairly adequate for their services. Indeed, medical men in the best class of practice in country towns and rural districts found a club practice such as he had indicated was really the backbone of a general practice, for it was an introduction to a private practice. These practices were considered very much more valuable and more transferable when they had a good sprinkling of club patients. But the thing they had now to deal with was something quite different. Here they had people pestered to join these societies by a succession of agents, male and female, and he said that it was the duty of the Council to interfere for the protection both of the profession and the public.

Mr HORSLEY expressed a preference for the motion standing in the name of Mr Brown.

Dr PYE-SMITH expressed the same preference. As for the word "touting" it was scarcely English and although it was supposed to be expressive no one knew exactly what it did express and he suggested that "soliciting" would be a better word to use.

The PRESIDENT suggested the expression "systematic canvassing."

Dr MCVAIL said he would like to know whether the Council intended to take action in this matter. He would like to know whether next November or next May they intended to proceed against practitioners who did the thing complained of. If they did not intend to take action then they should not pass this resolution which would only be the expression of a pious opinion.

Mr TICHBORNE said he favoured Mr Brown's motion declaring that this conduct was unprofessional.

Sir JOHN BATTY TUKE said that he would like to get some assurance that this was not the first stage in the construction of a new crime. They were certainly wasting time if they were merely going to say that this or the other thing was very naughty.

Dr GLOVER, replying on the whole debate, said he was perfectly willing to substitute for "touting" the words "systematic canvassing," although he considered the former a very expressive and well understood word. As to whether this motion was a piece of piety or a piece of resolution he said that so far as he was concerned it was a piece of intention and resolution and he thought that the words of the motion were quite sufficient to give notice to practitioners that if they lent themselves to such a system as he had illustrated and evidence was produced before the Council of a clear and satisfactory character, showing their implication in it, that the Council would be prepared to use their disciplinary powers. In doing so they should be supporting a long and strong tradition of the profession. He would remind the Council that they had the opinion of the judges that it would be most natural and proper in a body like this to object to such a system of touting and canvassing. He assured the Council that so far as he was concerned he was in earnest in this matter.

The motion, altered to read "associations by which systematic canvassing and advertising," was then put to the Council and carried, no member holding up his hand against it.

Dr GLOVER gave notice that he would put upon the programme a motion to forward to the bodies concerned copies of both resolutions.

In the body of the committee's report the passage beginning "the general tenour of the complaints made to us is that canvassing on a large and promiscuous scale is practised" was made to read "promiscuous canvassing on a large scale."

The Recovery of Fines

The Council received the following recommendation from the Penal Cases Committee adopted on April 28th, 1899, in connexion with the penalty recently paid by Mr T. R.

Allinson and retained by the Receiver of Police in regard to which Mr. Maitland Mackenzie had advised that this was a proper case to take into the courts to test the point of law relating to penalties —

That the committee recommend the Council to bring an action for the recovery of the fee and to instruct Mr. Porter to that effect.

The Executive Committee on May 29th passed the following resolution on this subject —

That the Executive Committee approve of the recommendation of the Penal Cases Committee and advise the Council to take the legal proceedings referred to and that the documents be referred to the Committee on Fines under the Medical Acts.

The Council also received the following report from the Committee on Fines under the Medical Acts, viz. —

The Committee on Fines, while thinking that the number of the Home Secretary on the subject of fines under the Medical Acts should have been directly referred to them for consideration, approve of the action taken by the Penal Cases Committee and the Executive Committee respectively in obtaining Mr. Maitland Mackenzie's opinion relative to the legality of the claim of the Receiver of the Metropolitan Police to take all such fines.

The committee further approve of the recommendation made by Mr. Maitland Mackenzie that an action-at-law should be undertaken by the Council to test the claim above stated.

The Colonial List
J. G. GUYER, Chairman.

On the motion of Mr. HORSLEY, seconded by Dr. BRUCE, it was agreed —

That the application of Miss Rachel Cohen, M.B. Calcutta, to register in the Colonial List the diploma F.R.C.S.I. which she has obtained be accorded, and that the Registrar be directed to return to register additional or higher qualifications in the Colonial List.

The Case of Alfred Freeman
The Council sat for a considerable time during this afternoon in camera and among the decisions arrived at was the following —

That the recommendation of the Executive Committee respecting the case of Alfred Freeman be adopted and that accordingly the Registrar be instructed to restore the name and qualification of Alfred Freeman to the Medical Register.

The Council adjourned.

Wednesday, June 7th
The Council resumed to-day, Sir William TURNER being in the chair.

Medical Aid Association
In the course of adjusting the minutes of the previous sitting the Council altered the resolution with regard to medical aid associations so as to read as follows —

Associations which systematically practise earning and advertising for the purpose of procuring patients.

The "Abounding Eloquence" of Members
Mr. CARTER said he should like to make a suggestion in favour of the despatch of business. They were all of them exceedingly anxious to conclude the business of the session as quickly as possible and they were all of them conscious that the recent sessions of the Council had been a good deal prolonged. Their last session which might have been finished in five or six days was extended to nine days and they were all eloquent of certain members of the Council, two of whom in two or six days made between them 133 speeches. It might be conducive to the despatch of business if there was an understanding that no member should speak more than three times on each motion.

The Proceedings against the late Mr. H. K. Hunter
The first item of business on the programme was a notice by Mr. HORSLEY, "To draw attention to the proceedings taken in the name of the Council against the late Mr. H. K. Hunter, L.S.A." After some preliminary discussion the Council decided to postpone the matter until to-morrow and to ask the legal assessor and the solicitor to be in attendance then.

The Efficiency of Examinations
Mr. HORSLEY moved
That the Council receive the opinion that by Sections 12 and 20 of the Medical Act 1886, thereby it is imposed on the Council of inquiry into and scrutiny as far as possible the efficiency of any examination which and returning any registrable qualification mentioned in Schedule A of the Act.

He explained that he and Dr. Bruce had put this motion on the paper from the purely academic point of view and he trusts that it would not be necessary for him to repeat the observations he made the other day relative to the interpretation of the Medical Acts. He would only once more ask the Council to decide on this matter.

Mr. HORSLEY moved
That the Council receive the opinion that by Sections 12 and 20 of the Medical Act 1886, thereby it is imposed on the Council of inquiry into and scrutiny as far as possible the efficiency of any examination which and returning any registrable qualification mentioned in Schedule A of the Act.

He explained that he and Dr. Bruce had put this motion on the paper from the purely academic point of view and he trusts that it would not be necessary for him to repeat the observations he made the other day relative to the interpretation of the Medical Acts. He would only once more ask the Council to decide on this matter.

On the motion of Mr. TURNER the name of Mr. Carter was added to the Committee on Dispensings.

The First Year of Medical Study
The next business was the reception of a report by the Council to think in reading the Act, as he did, that Section 30 did not in any way invalidate the application of Sections 18 and 20. That was all he asked the Council to affirm by this motion.

Dr. BRUCE seconded the motion.
The PRESIDENT asked Mr. Horsley to show the bearings of Section 3 of the Act of 1886 upon this question.
Mr. HORSLEY replied that the bearing of Section 3 of the Act of 1886 upon this question was to his mind nil. That section for the first time introduced a new feature into the Medical Acts. It introduced a statutory statement as to the bare minimum upon which a man could gain entry to the Register. But if they were to interpret Section 3 of the Act of 1886 in the manner indicated by some members of the Council the other day then they should have to say that the term "qualification" was restricted absolutely in the sense of the Act of 1886. But it that were so of course the Registrar would have repeated the Act of 1886 altogether or at any rate those sections in which such a restricted term appeared.

The PRESIDENT said there was another question he would like to ask. Had Mr. Horsley considered whether the Registrar of the Council would be in a position to decline to put on the Register as an additional qualification a Fellowship for which there had been no examination? Had he considered how that bore upon the point raised in the motion?

Mr. HORSLEY said it did not bear upon the point at all. It was a question no doubt of great importance, but it was one for discussion, and a very fit one for discussion, by the Council. The only thing that could be said in relation to a matter of that kind was that this Council had recognised certain qualifications for which in most instances an examination was required, but he was not aware that this Council, in expressing its recognition of any Fellowship for instance, had laid down the condition that it must be secured by examination. He thought it ought to have done so, but that was another matter. He was not aware that this Council had in any way made that a condition and until it did make it a condition then he submitted that this did not come into his point.

Dr. MACALISTER said that Section 20 of the Act of 1886 appeared to him directly to contemplate such qualifications as might follow a course of study and examination and no others. The section said, "In case it appear to the General Council that the course of study and examination to be gone through in order to obtain any such qualification from any such college or body are not such as to secure the possession of the necessary knowledge and skill for the efficient practice of their profession, it shall be lawful for such General Council to represent the same to Her Majesty's most honourable Privy Council." That seemed to him to limit the qualifications to those obtained after a course of study and examination and the sufficiency of these examinations was naturally a matter which could be inquired into if the qualification was one which admitted to the Register and not otherwise. He did not see how they could get out of that.

Dr. BRUCE said that the view of the matter which he took was that as long as men were allowed to be put on the Register they should not shut the door against inquiry into the nature of their qualification.
After further debate a vote was taken, when seven members voted for the motion, nine members voted against it, 12 did not vote on either side, and two were absent. The motion was accordingly lost.

The Legal Advisers
In response to a question addressed to the chair by Mr. HORSLEY the REGISTRAR read a memorandum giving a historical account of the position of the legal assessor and the solicitor to the Council.
Mr. TURNER brought up a recommendation from the Dental Committee as to adopting a new standing order for regarding procedure in dental penal cases. The Council decided that the new standing order required some adjustment and its adoption was in consequence postponed.

The Committee on Dispensings
On the motion of Mr. TURNER the name of Mr. Carter was added to the Committee on Dispensings.
The First Year of Medical Study
The next business was the reception of a report by the Council to think in reading the Act, as he did, that Section 30 did not in any way invalidate the application of Sections 18 and 20. That was all he asked the Council to affirm by this motion.

Dr. BRUCE seconded the motion.
The PRESIDENT asked Mr. Horsley to show the bearings of Section 3 of the Act of 1886 upon this question.
Mr. HORSLEY replied that the bearing of Section 3 of the Act of 1886 upon this question was to his mind nil. That section for the first time introduced a new feature into the Medical Acts. It introduced a statutory statement as to the bare minimum upon which a man could gain entry to the Register. But if they were to interpret Section 3 of the Act of 1886 in the manner indicated by some members of the Council the other day then they should have to say that the term "qualification" was restricted absolutely in the sense of the Act of 1886. But it that were so of course the Registrar would have repeated the Act of 1886 altogether or at any rate those sections in which such a restricted term appeared.

The PRESIDENT said there was another question he would like to ask. Had Mr. Horsley considered whether the Registrar of the Council would be in a position to decline to put on the Register as an additional qualification a Fellowship for which there had been no examination? Had he considered how that bore upon the point raised in the motion?

Education Committee on the regulations of the Conjoint Boards in England and Scotland concerning the first year of medical study

A large part of the report was devoted to a historical review of the situation too long to summarise. Following this there were the following "remarks by the committee," viz. —

The committee in presenting the foregoing historical statement desire to call the attention of the Council to the two questions, distinct but interconnected which it involves. First, the question whether a year of scientific study before registration should in exceptional cases be recognised as constituting one of the five years of the medical curriculum. Second, the question whether a year of scientific study taken after registration, but in an institution of the status and character of an ordinary secondary or grammar school, should regularly be recognised as constituting one of the five years required.

The first question is that raised by the enactment of Section 1 of the Scottish Universities Ordinances. The committee and the Council repeatedly protested against this section both as being a dangerous precedent and as unnecessary for the relief of the *bona fide* cases of exemption contemplated by the Commissioners. Experience seems to have justified the protest on both grounds. According to the information before the committee Section 1 has not been utilised to any great extent. In Aberdeen no cases of exemption have occurred, in Edinburgh five, and in Glasgow four. But the committee understand that in all the cases examinations qualifying for registration had been passed indeed in two of the Glasgow cases the applicants for exemption were already graduates in arts. The section was therefore for its proposed purpose superfluous as any formal difficulty it was devised to remove could have been met in other ways to which no objection could be taken. But the example set by this enactment has apparently had the influence which the Council apprehended and the new regulations of the Conjoint Boards in England and Scotland illustrate the manner of its operation.

The second question had been formally raised at the time when the Conjoint Board in England obtained from the Council the concession that scientific study before registration should qualify for the first examination, would in the committee's opinion have been answered in the negative by the Council. One chief object of the Council's action has been to secure that ordinary school work should be completed and tested by a sufficient preliminary examination before the course of medical study was begun. It has been felt that to be truly profitable to the medical student his work at the ancillary sciences should be conducted under higher conditions and under better safeguards as to efficiency than can be looked for in secondary schools, the majority of whose pupils are still boys and girls. The wholesale recognition of ordinary day schools as teaching institutions "in which the first year of medical study may be pursued must practically frustrate this object and bring about the result foreseen by the committee in their report of May 24th 1894. They would in particular call the Council's attention to the following paragraph:—

The committee, however cannot help regarding the system with considerable distrust. First, because in practice it may tend to the recognition of an inferior class of schools; secondly, because the standard of examination in science may as a consequence be so lowered as practically to lead to the waste of the first year of study; thirdly, because it does not explicitly provide for any preliminary examination in the ordinary school subjects before the special scientific subjects are begun; and fourthly because though the Conjoint Boards have safeguarded their system by requiring five years of medical study after registration of such schoolboy students, it is open to any other licensing body to require only four years.

As to the remedy, the committee still feel the difficulty pointed out in their report of 1894 of the Council taking action in regard to the inspection and direct recognition of teaching institutions. But it appears now that the check proposed by the committee and adopted by the Council on the recognition of such institutions "after due inspection by the licensing bodies has proved insufficient in two ways. In the first place contrary to the Council's intention a considerable number of secondary and even of board schools have been admitted to recognition. In the second place, the duty of inspection delegated to the licensing bodies has not been carried out in all cases.

The committee have definitely ascertained that the Conjoint Board in England has recognised certain "teaching institutions" for the purposes of instruction examination, and registration, without the guarantee which inspection affords that the said institutions are adequately equipped and efficiently conducted. The chairman of the committee wrote to the secretary of the Board on Feb. 8th asking whether the following schools had been inspected. Nonconformist Grammar School Bishop's Stortford Bristol Grammar School The Grammar School Bromyard Felsted School, Felsted Higher Grade Board School, Hanley Mercers School Holborn Higher Grade Board School, Norwich Higher Grade Board School Portsmouth Grammar School, Portsmouth Forest Schools, Walthamstow Grammar School Woodford, Essex. The following is the reply:—

Examination Hall Victoria Embankment,

London, W.C. March 21st, 1899

DEAR SIR JOHN BATTY TUKE.—I have now submitted your letter of the 3rd ult. to the committee of management of this board and I am desired to inform you that the following resolution was adopted by them in reference to your request for information as to the recognition of institutions viz. —

"That whilst the committee of management are of opinion that the question of the recognition of institutions is entirely one for the respective examining bodies to determine for themselves Sir John Battaty Tuke be informed that the following schools mentioned by him have been visited and reported on favourably by members of the committee viz.: Felsted School, Mercers School Holborn Higher Grade Board School Portsmouth Forest School, Walthamstow Bancroft School, Woodford Essex; and that the other mentioned by him were accepted after the committee had satisfied themselves that the schools fulfilled the requirements of and were recognised by, the South Kensington Science and Art Department.

I return your marked list of schools.

Yours very truly,

FREDERIC G. HALLET, Secretary

Sir John Battaty Tuke, M.D.

The committee have thus to report that the recognition of "teaching institutions where physics, chemistry and elementary biology are taught" without due inspection, is not in accordance with Resolution II agreed to by the Council on Dec. 4th 1894.

It therefore appears to the committee necessary that the Council should now take a further step. The licensing bodies should be informed that schools for boys and girls were not intended by the Council to be regarded as institutions at which the first of the five years of medical study may be spent and the Council should require that before registration is effected a student should have commenced medical study at a university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council. If this were done the recognised institutions would not merely, as now be reported to the Registrar, but would come in a regular and formal way before the Council for its approval. Attention could thus be drawn to any institution regarding which objection might be taken and approval withheld if the evidence as to its status and efficiency were unsatisfactory. As registration is a matter over which the Council alone has control this manner of dealing with the difficulty appears to be the least open to objection.

RECOMMENDATIONS

I. That the regulations in regard to registration from and after Jan. 1st, 1900, be amended as follows:—

REGULATIONS IN REGARD TO REGISTRATION

No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council and has produced evidence that he has commenced medical study at a university school of medicine, or scientific institution recognised by one of the licensing bodies and approved by the Council.

Each of the branch registrars shall keep a register of medical students according to the subjoined form.

Form for the Registration of Medical Students

Name.	Preliminary examination of arts, with date thereof	Date of Registration.	Place and date of commencement of study as certified by an official of a university, school of medicine, or scientific institution approved by the Council.

II. That the Registrar be directed to call the attention of the licensing bodies to the foregoing resolution.

The report was formally received and entered on the minutes

SIR JOHN BATTY TUKE, seconded by Dr MACALISTER, moved the adoption of the first recommendation

The PRESIDENT said that as he understood the situation the change recommended by the committee was the insertion of the words "and approved by the Council"

Mr CARTER asked whether it was proposed to institute inspection of the bodies because if it was not then he failed to see how they were going to proceed.

The PRESIDENT pointed out that the Council had no power under the Act to inspect teaching institutions

Mr CARTER said he would like to know how they were going to reach the mental condition of approval.

Sir CHRISTOPHER NIXON suggested that the licensing bodies could inspect the institutions and this Council could act upon their report

Sir RICHARD THORNE said it was no uncommon thing for a Government department to approve a thing without actually inspecting it

Dr MACALISTER said that registration was a matter for this Council alone and it was suggested that it should only take place in connexion with institutions which had been brought formally before the Council and had been approved by the Council in the sense that no objection had been raised to them. What happened at present was that the body sent up to the Registrar a list of the institutions which during the year had been recognised after due inspection by the body and that list remained in the hands of the Registrar, and the Council never said anything about it. It was surely desirable that this list should come before the Council and be put in print and circulated and if a member happened to see on the list an institution about which he had views or information then he could raise a question about it in the Council and the matter could be discussed. All they wanted was to give the members of the Council an opportunity to object to any institution which, in their opinion, ought not to be recognised

Mr BRYANT said that this report contained a principle which he was afraid his College (the Royal College of Surgeons of England) could not accept. Hitherto this Council had allowed all the examining bodies to select the institutions they recognised, and in the case of his own

College there were a few institutions which had not been inspected though they were recognised. If the Council objected to the want of inspection he had little doubt it could be arranged. But he did not see why it was necessary that the institutions recognised should be approved by the Council. In such a matter the Council must rely on the Sir DICK DICKINSON said his position as the representative of the Royal College of Physicians of London was the same as that of Mr. Bryant. This was a new departure with a vengeance and one which would destroy the autonomy of the Royal Colleges who held their privileges by charter and who meant to stand by these privileges whatever the Council might say or do. He could not help thinking that this recommendation was presented under a false conception of the duties of the Council.

Mr. CARTER said that he was afraid this recommendation would weaken the sense of responsibility in the examining bodies themselves.

Dr. CHURCH proposed that the old form should be retained.

Sir PHILIP SMITH said that he had been instructed to see that the five years' course of study was not cut down to four years.

Sir RICHARD THORNTON remarked that according to the speeches made during the afternoon the proposed action of the Council was absolutely illegal. He sympathised very much with the report. He was perfectly satisfied that an attempt was being made to while away the five years' education as they got under the four years' curriculum. The President said that the point at issue really was this—it was not that the two London Colleges declined to submit to the Council's recommendations, but, as understood their contention, they declined to limit their functions to the question of approval.

Sir WILLIAM GAYLOR said that he felt considerably relieved by Dr. Macalister's remark that the Joint Board were keeping within the letter of the law, although they might have expanded their ideas. He reminded the Council that they were confronted by an educational movement which amounted practically to a revolution—that was to say, science had been introduced into the school curriculum to a much greater extent than it was thought some years ago that it would be possible to introduce it. The Council must take care that in anything they did they did not hamper this educational movement, which was distinctly of the greatest importance not only to the medical profession, but also to other departments in the social system. He did not think that the Council should interfere with that movement at all. On the contrary, he was of opinion that the movement in question should be taken full advantage of. Let he was of the view that nothing of science which was taught in school should count as part of the medical curriculum.

Dr. BRUCE said that he entirely sympathised with the view of Sir William Gaynor as to the great advantage of science being taught in the grammar school, but as they had put it in their regulations that a certain amount of science was a part of that medical study it seem to him quite plain that the matter came within the purview of the General Medical Council. Therefore it was the Council's duty to see that the subjects were properly taught.

Mr. TILLY said that it struck him that there were just two points that had not been particularly referred to during this discussion. When the Council decided upon adding a fifth year to the curriculum it was understood that the fifth year was to be a clinical year. Then members of Council thought that as there was to be a period of five years for study they might as well decide upon introducing elementary subjects which had not been required before. That introduced a difficulty as to the arrangement, and he was quite certain that the efforts of the Royal Colleges of England had been put forward to get over that entanglement. He believed that the Royal Colleges wished to make a genuine attempt by what they proposed to get rid of this first year's study had been spoiled by the addition of these preliminary subjects.

After some further conversation, in the course of which the President said that there was nothing before the Council but the motion of Sir John Batty Tuke.

Dr. CHURCH said that he was prepared to move as an amendment the following:

That in the regulations in regard to restriction the word "lectures" before "tutorials" be omitted, and that the concluding words "approved by the Council" be also omitted.

He took the present case as a test one. If the Council felt that it was not in its power to deal with such a case it would perhaps throw out the recommendation of the Education Committee, but if it did that he was afraid that they would be going on the downward path and all that they had done in the way of advancing education would be lost.

Mr. BROWN hoped that the Council would adopt this report without any fear of the dire consequences which some members had threatened. He maintained that if the first year of study was to be study in science in a grammar school that would be a disastrous thing for medical education. If they recognised grammar-school education they would have boys of 14 or 15 years of age entering upon the second year of professional study. He should strongly support the committee in their recommendations.

Dr. MACALISTER maintained that the Colleges, the Joint Board, had been strictly within the letter of the law.

Sir J. BATTY TUKE. Yes, within the strict letter of the law.

Dr. MCLELLAN supported the committee in the report that they had made. He thought, however, that that report was too mild and that it ought to have been couched in very much stronger language. In his opinion it would be ridiculous if the two Colleges in question and the General Medical Council were to go before the Privy Council on such a trivial matter.

Dr. LOUISE ATTHILL expressed the opinion that a systematic effort was being made to whittle down the five years' course. He objected to that, notwithstanding that he believed that medical students now did not get such good education as they got under the four years' curriculum.

The President said that the point at issue really was this—it was not that the two London Colleges declined to submit to the Council's recommendations, but, as understood their contention, they declined to limit their functions to the question of approval.

Mr TEALE seconded this proposal

Sir JOHN BATTY TUKE, in reply on the whole debate, expressed regret that the only amendment to the committee's proposal had come from a member of the committee. He was sorry to inform some of the lately appointed members of the committee that as the Medical Acts were generally read the General Medical Council had comparatively little power over medical education, but he had always held, and still held, that they had great power in this—the loyalty of the various licensing bodies to the General Medical Council. That was a moral force. If it had not been for it medical education would not have arrived at its present advanced state. And he must say that the speeches of the two representatives of the two English Colleges ought not to have been heard that day. He was charitable enough to believe that there was a considerable amount of misunderstanding as regards the loyalty of these two bodies to the General Medical Council, and he hoped that their future action would show that that was correct.

The Council divided on the amendment proposed by Dr Church, with the result that nine voted for the amendment and 16 against it. On the names being called and the numbers taken it was found that 17 were against the amendment and nine for it.

The amendment accordingly was rejected.

Mr BRYANT rose, he said, to propose a further amendment. He did think that his College—the Royal College of Surgeons of England—or rather the Conjoint Board of England, had on this occasion been badly treated by the Council. Whether it was an intentional misunderstanding of the fact of the case he did not know, but he thought they had not been well treated. It was not their fault if there was anything wrong in regard to teaching institutions recognised by the Council, for he had repeatedly stated that the principle of the management of the two Colleges had been to visit and inspect every institution which had been recognised by them. No doubt at the beginning some had been excluded at the instance of the South Kensington authorities, but what he distinctly told the Council now was that they would be perfectly willing to undertake the visiting and inspection of even these excluded institutions. He proposed—

That the following be adopted instead of the recommendation of the committee—namely that the list of recognised teaching institutions forwarded to the Registrar at the beginning of each year be returned to the next following meeting of the Executive Committee and printed in the minutes of that committee for the information of the Council.

Sir J. BATTY TUKE said that this amendment was no more than a repetition of what the Council had already voted upon and rejected.

On a division eight voted for the amendment and 18 against. On the original motion being put to the vote it was carried by 18 votes to six, five members declining to vote and one being absent.

On the motion of Sir J. BATTY TUKE, seconded by Dr MACALISTER, it was unanimously agreed that the Registrar should be directed to call the attention of the licensing bodies to the resolution just arrived at.

Penal Cases Committee

On the motion of Dr BRUCE, seconded by Dr ATTWILL, it was agreed—

That the number of the members of the Penal Cases Committee be the same as that of the Executive Committee—viz. eight exclusive of the President, four from England, two from Scotland and two from Ireland.

The Council adjourned

PROVIDENT MEDICAL ASSOCIATION—By the invitation of Lady Hope and Mr T. A. Denny a drawing room meeting was held at 7, Connaught-place on Tuesday, June 6th, in support of the work of the Metropolitan Provident Medical Association, the object of which is to provide efficient medical treatment for those of the working classes who are unable to pay the usual fees on a system of mutual assurance by small periodical payments. There are 20 branches, 15 of which are dispensaries and five medical clubs, from which 11,441 membership cards, family and single were issued last year, the payments amounting to £5304. A resolution to the effect that it was necessary to work in coöperation with the hospitals under rules approved by the medical profession, and that branches should be formed in every district in London, on the system of this association was carried.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE—*Amsterdam* Dr H. Timmer has been recognised as *privat docent* of Orthopedics—*Bahia* Dr Joaquim Mathews dos Santos has been appointed Professor of Hygiene—*Grat* Dr E. Payr has been recognised as *privat docent* of Surgery—*Kieff* Dr J. Landenbach has been appointed to the chair of Pharmacology.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND—At the monthly meeting of the College held on June 2nd Mr George Thorpe, L.S.A., having passed a special examination for the Licence in Medicine of the College, was admitted by the President and Fellows to the Licence.

ROYAL COLLEGE OF SURGEONS IN IRELAND—At a meeting of the Fellows held on June 5th the following officers were elected for the ensuing year—President Mr Robert Lafayette Swan, Vice-President Dr Thomas Myles, Honorary Secretary Sir Charles A. Cameron, O.B., Council Professor Archibald H. Jacob, Professor Edward Hallaran Bennett, Sir Philip Crampton Smyly, Sir William Stokes, Mr Henry Rosborough Swanzy, Professor William Stoker, Dr William Ireland Wheeler, Sir William Thomson, Mr Austin Meldoun, D.L., Sir Charles A. Cameron, O.B., Dr L. Heperstal Ormsby, Dr Richard D. Parefoy, Dr John J. Cranny, Mr Henry Gregg Sherlock, Professor John B. Story, Dr Henry Fitzgibbon, Dr Francis T. Heuston, Mr John Lentaigue, and Dr Richard Bolton McCausland.

THE DEVON QUEEN VICTORIA COMMEMORATION FUND—The Finance Committee of this fund reported on May 29th that the fund now consists of £5800, giving a net income of £173 together with reversions which will come in at the expiration of existing leases. A scheme is to be submitted for the distribution of this amount among hospitals and convalescent homes. The committee appeal for further subscriptions and hope that a renewed effort will be made to endow the County Hospital Fund with an income sufficient to give material assistance to the various medical institutions of Devonshire.

THE "STREETS AND SQUARES BAZAAR" IN AID OF ST MARY'S HOSPITAL—On June 6th and 7th a bazaar in aid of St Mary's Hospital and the Clarence Memorial wing was held at the Hotel Great Central in the Marylebone road, London. On the first day the bazaar was opened by H.R.H. Princess Louise, Duchess of Fife, who was accompanied by her husband, the Duke of Fife. The stalls, which were 28 in number, were named after some of the principal streets, squares, and thoroughfares in the west and north west of London and many of the charitable ladies who presided over them were well known leaders of fashionable society. Members of the theatrical and musical professions lent their aid in making the bazaar a success and the bands of the Royal Horse Guards and the Royal Engineers played during each day. It is to be hoped that the hospital will be benefited by a large amount. The management of the hotel very generously handed over the whole of the receipts for luncheon and dinner received on June 6th to the funds of the hospital.

THE DROITWICH BRINE BATHS—A new station on the Great Western Railway which marks a decided advance in the progress of the old town of Droitwich was opened on June 3rd. Of recent years much has been done to attract visitors to English health resorts and bathing places and at Droitwich, which has come in for its share of increased popularity, the old station has been found to be too small to accommodate the increasing number of visitors, hence the building of the new one. The opening ceremony was performed by Sir A. F. Godson M.P., in the unavoidable absence of Mr Corbett, who gave the ground on which the new station was built. Mr D. McKer, a director of the Great Western Railway Company, remarked on the present occasion that Droitwich Station was opened in 1852 and that 12 years later there were only seven trains daily between it and London, the fastest train taking five and a half hours to make the journey. Now there were

Mr TEALE seconded this proposal

Sir JOHN BATTY TUKE, in reply on the whole debate, expressed regret that the only amendment to the committee's proposal had come from a member of the committee. He was sorry to inform some of the lately appointed members of the committee that as the Medical Acts were generally read the General Medical Council had comparatively little power over medical education, but he had always held, and still held, that they had great power in this—the loyalty of the various licensing bodies to the General Medical Council. That was a moral force. If it had not been for it medical education would not have arrived at its present advanced state. And he must say that the speeches of the two representatives of the two English Colleges ought not to have been heard that day. He was charitable enough to believe that there was a considerable amount of misunderstanding as regards the loyalty of these two bodies to the General Medical Council, and he hoped that their future action would show that that was correct.

The Council divided on the amendment proposed by Dr O'Rourke, with the result that nine voted for the amendment and 16 against it. On the names being called and the numbers taken it was found that 17 were against the amendment and nine for it.

The amendment accordingly was rejected.

Mr BRYANT rose, he said, to propose a further amendment. He did think that his College—the Royal College of Surgeons of England—or rather the Conjoint Board of England, had on this occasion been badly treated by the Council. Whether it was an intentional misunderstanding of the fact of the case he did not know, but he thought they had not been well treated. It was not their fault if there was anything wrong in regard to teaching institutions recognised by the Council, for he had repeatedly stated that the principle of the management of the two Colleges had been to visit and inspect every institution which had been recognised by them. No doubt at the beginning some had been excluded at the instance of the South Kensington authorities, but what he distinctly told the Council now was that they would be perfectly willing to undertake the visiting and inspection of even these excluded institutions. He proposed—

That the following be adopted instead of the recommendation of the committee—namely that the list of recognised teaching institutions forwarded to the Registrar at the beginning of each year be returned to the next following meeting of the Executive Committee and printed in the minutes of that committee for the information of the Council.

Sir J BATTY TUKE said that this amendment was no more than a repetition of what the Council had already voted upon and rejected.

On a division eight voted for the amendment and 18 against. On the original motion being put to the vote it was carried by 18 votes to six, five members declining to vote and one being absent.

On the motion of Sir J BATTY TUKE, seconded by Dr MACALISTER, it was unanimously agreed that the Registrar should be directed to call the attention of the licensing bodies to the resolution just arrived at.

Penal Cases Committee

On the motion of Dr BRUCE, seconded by Dr ATTHILL, it was agreed—

That the number of the members of the Penal Cases Committee be the same as that of the Executive Committee—viz. eight, exclusive of the President, four from England, two from Scotland, and two from Ireland.

The Council adjourned

PROVIDENT MEDICAL ASSOCIATION—By the invitation of Lady Hope and Mr T A Denny a drawing room meeting was held at 7, Connaught-place on Tuesday, June 6th, in support of the work of the Metropolitan Provident Medical Association, the object of which is to provide efficient medical treatment for those of the working classes who are unable to pay the usual fees on a system of mutual assurance by small periodical payments. There are 20 branches, 15 of which are dispensaries and five medical clubs, from which 11,441 membership cards, family and single, were issued last year, the payments amounting to £5304. A resolution to the effect that it was necessary to work in co-operation with the hospitals under rules approved by the medical profession, and that branches should be formed in every district in London on the system of this association was carried.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE—*Amsterdam* Dr H Timmer has been recognised as *privat docent* of Orthopædics—*Bahia* Dr Joaquim Mathews dos Santos has been appointed Professor of Hygiene—*Grat* Dr E Payr has been recognised as *privat docent* of Surgery—*Kieff* Dr J Landenbach has been appointed to the chair of Pharmacology

ROYAL COLLEGE OF PHYSICIANS OF IRELAND—At the monthly meeting of the College held on June 2nd Mr George Thorpe, L.S.A., having passed a special examination for the Licence in Medicine of the College, was admitted by the President and Fellows to the Licence.

ROYAL COLLEGE OF SURGEONS IN IRELAND—At a meeting of the Fellows held on June 5th the following officers were elected for the ensuing year—President Mr Robert Lafayette Swan, Vice-President Dr Thomas Myles, Honorary Secretary Sir Charles A. Cameron, O.B. Council Professor Archibald H. Jacob, Professor Edward Hallahan Bennett, Sir Philip Crampton Smyly, Sir William Stokes, Mr Henry Rosborough Swanzy, Professor William Stoker, Dr William Ireland Wheeler, Sir William Thomson, Mr Austin Meldon, D.L., Sir Charles A. Cameron, O.B., Dr L. Hepcstal Ormsby, Dr Richard D. Pursey, Dr John J. Cranny, Mr Henry Gregg Sherlock, Professor John B. Story, Dr Henry Fitzgibbon, Dr Francis T. Houston, Mr John Lentaigno, and Dr Richard Bolton M'Causland.

THE DEVON QUEEN VICTORIA COMMEMORATION FUND—The Finance Committee of this fund reported on May 29th that the fund now consists of £5800, giving a net income of £173 together with reversions which will come in at the expiration of existing leases. A scheme is to be submitted for the distribution of this amount among hospitals and convalescent homes. The committee appeal for further subscriptions and hope that a renewed effort will be made to endow the County Hospital Fund with an income sufficient to give material assistance to the various medical institutions of Devonshire.

THE "STREETS AND SQUARES BAZAAR" IN AID OF ST MARY'S HOSPITAL—On June 6th and 7th a bazaar in aid of St Mary's Hospital and the Clarence Memorial wing was held at the Hotel Great Central in the Marylebone-road, London. On the first day the bazaar was opened by H.R.H. Princess Louise, Duchess of Fife, who was accompanied by her husband, the Duke of Fife. The stalls which were 28 in number, were named after some of the principal streets, squares, and thoroughfares in the west and north west of London and many of the charitable ladies who presided over them were well known leaders of fashionable society. Members of the theatrical and musical professions lent their aid in making the bazaar a success and the bands of the Royal Horse Guards and the Royal Engineers played during each day. It is to be hoped that the hospital will be benefited by a large amount. The management of the hotel very generously handed over the whole of the receipts for luncheon and dinner received on June 6th to the funds of the hospital.

THE DROITWICH BRINE BATHS—A new station on the Great Western Railway which marks a decided advance in the progress of the old town of Droitwich was opened on June 3rd. Of recent years much has been done to attract visitors to English health resorts and bathing places and at Droitwich, which has come in for its share of increased popularity, the old station has been found to be too small to accommodate the increasing number of visitors, hence the building of the new one. The opening ceremony was performed by Sir A. F. Godson, M.P., in the unavoidable absence of Mr Corbett, who gave the ground on which the new station was built. Mr D. McIver, a director of the Great Western Railway Company, remarked on the present occasion that Droitwich Station was opened in 1852 and that 12 years later there were only seven trains daily between it and London, the fastest train taking five and a half hours to make the journey. Now there were

FRANCIS.—On June 1st, at Wright-street, Hull the wife of A. G. Francis, B.A. M.B. B.S. F.R.C.S. of a daughter.

GIBBS.—On June 1st, at Chestnut Lawn Stechford, Birmingham, the wife of T. Harold Gibbs M.B. B.S. Dunelm. of a son.

OLIVER.—On May 31st at Westdene, Maidstone, the wife of Charles Fye Oliver, M.D. Lond., D.P.H. of a son.

MARRIAGES

BLYTH—ARMSTRONG.—In Denwell Parish Church, on June 1st, by the Rev Herbert Bott M.A., vicar of St. Aidan's assisted by the Rev A. L. Curry M.A., Meredith Wynter Blyth B.A. B.Sc. son of Dr A. Wynter Blyth, Medical Officer of Health, St. Marylebone London, to Chrissy Mary eldest daughter of Henry B. Armstrong, D Hy Medical Officer of Health, Newcastle-upon-Tyne.

BUNCOMBE—BOUSEFIELD.—On June 1st, at All Saints Foregate, by the Rev T. F. Williams, M.A. Vicar William Dewey Buncombe Medical Superintendent of City of London Infirmary, Bow road, elder son of the late Charles Hope Buncombe F.R.C.S., of Bow and Putney to Henrietta Mary elder daughter of William Jeune Bousfield of Forest-gate, Essex.

COOKE—JONES.—On June 6th, at the Welsh Calvinistic Methodist Chapel Garston, by the Rev W. O. Jones, B.A., Ebenezer Hunt Cooke, M.A. M.B. of Bhusawal India, son of the Rev J. Hunt Cooke of Crouch End to Katie Williams, only daughter of R. W. Jones, of Garston Liverpool.

DODD—DE SOLOME.—On June 1st, at Holy Trinity Church, Folkestone, Percy Vernon Dodd M.A., M.D. of Manor road, Folkestone to Marion Maud, younger daughter of the late Anthony de Solome of Boulogne-sur-Mer.

LETHBRIDGE—BELLETT.—On June 1st, at St. Mary's, Radpole, Weymouth Sir Alfred Swaine Lethbridge K.C.S.I. M.D. Late Indian Political Service I.M.S. to Edith Seymour widow of the late George Bellett, M.A. Bengal Educational Service.

POLLARD—EVAN-SMITH.—On June 1st, at St. Philip's, Kensington George Wilfred Pollard M.D. eldest son of George H. Pollard, Esq. of Grassendale Taunton to Ella MacLaurin second daughter of R. MacLaurin Evan-Smith Esq. of Earl's-court-road W.

RENDALL—WATSON.—On June 1st, at St. Mary Abbot's, Kensington, Percy Rendall M.D., of Oxenwood, Chesham Surrey to Edith, daughter of Edward Watson, of South Woodford, Essex.

RUCK—FLUMMER.—On June 1st at the Parish Church, Saddington, Gloucestershire David Naughton Ruck, M.R.O.S. W.L.R.P., of Ealing to Elsie Davis second daughter of William Matthew Plummer, of Saddington.

WILSON—KEMP.—On June 1st at St. Mary's Charlecombe Bath George Wilson, M.D. or Warwick to Aileen Ruth eldest daughter of Edward Chippendall Kemp, J.P. of Dacca, India.

DEATHS

COGHILL.—On June 5th at Ventnor of peritonitis, John George Sinclair Coghill M.D. F.R.C.P.E. M.R.O.P. Senior Physician of the Royal National Hospital for Consumption Ventnor aged 65 years. Scotch and China papers please copy.

HINDLE.—On March 5th, at 41, Railway road Darwen, Lancs, George Hindle M.R.O.S. L.S.A. Lond. aged 49 years.

KERR.—On May 30th, at Wollington square Hastings Norman Kerr M.D. F.R.S. aged 65 years.

LEY.—On June 1st, at the residence of his brother, Longfield road Ealing W. Edwin Granville Ley M.D. Deputy Surgeon General, late A.M.D.

MOIR.—On June 7th at St. Andrews, N.B. Robert Moir M.D., F.R.O.S.E. Surgeon Major (retired), Indian Medical Service.

A B—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

grown and badly-developed lad 17 years of age, a native of London, was sent down here by one of the leading physicians of the Brompton Hospital on Sept. 28th 1897 only as an experiment as the doctor was strongly of opinion that the lad's only chance of recovery was to take the long sea voyage to Australia and stay out there. I found on examination consolidation of the right base of the lung and all the symptoms of commencing phthisis. I thought this a favourable opportunity to try the 'open air' treatment, with extra feeding limited exercise and daily drill to expand the lung &c. Within a fortnight the lad had gained four pounds in weight, night sweats had disappeared, and the lung had greatly recovered its power and breathing space. He steadily improved in every way for six months then returned home, but had a slight relapse. He again came down and remained till the following September when he left with his lung sound and over a stone heavier in weight.

I am Sirs yours faithfully

CHARLES A. WIGAN, M.D. Durb., V.R.C.S. Eng

Portsmouth, Somerset, June 6th 1899

A HARD CASE.

To the Editors of THE LANCET

SIRS,—May I ask the assistance of THE LANCET in the following case? Mr Henry Raven F.R.C.S. Eng., who has lived and practised in the same parish over 40 years has suddenly been deprived of almost his sole means of support under the following circumstances. About 13 years ago he sold his practice in consideration of an annuity payable to himself and wife during their joint lives and during the life of the survivor. This annuity was paid regularly until about two years ago when the purchaser of the practice resold the same to another practitioner on the terms that the vendor should continue to pay the annuity and releasing the practice from the liability to pay the same. The vendor has failed to pay the annuity under circumstances which it is here unnecessary to detail. The annuitants are both in their eighty-third year. He is bed ridden paralysed, and stone deaf, she is blind. They have no children either to assist to support them or to look after them. As one of 10 children who in all their infantile maladies received the careful attention of the same kind hearted old practitioner, I am trying to raise a sum which will enable the aged couple to end their days without distress. Subscriptions will be thankfully received and acknowledged by Messrs. Barclay and Co., Bankers, or by

Your obedient servant,

Swaffham, Norfolk June 3rd 1899 A. J. WINTER, Solicitor

*A Mr Cadge, F.R.C.S. Eng., of Norwich writes:—I have known Mr Raven for quite 40 years as a worthy and excellent country practitioner. I gladly support Mr Winter's appeal and will with pleasure contribute £5 towards the fund which he is collecting"—Ed. L.

'ALWAYS HAVE A GOOD COAT ON YOUR BACK'

THESE words were the late Sir Andrew Clark's and came at the end of some very shrewd counsels addressed to a young medical friend just entering on practice. Not that Sir Andrew Clark was original in advising a strict attention to wearing apparel on the practitioner's part. The advice may in germ be found in Celsus, in the famous passage in which he dwells on the advantage of making a cheerful impression on the patient. He attaches much importance to the *hilaris vultus* (good humoured countenance) of the medical man and by implication puts his veto on any outward appearance (dress included) which the patient might find distasteful or repellent. The opposite extreme—dandyism—he would have found objectionable for the same reason. So-and-so was so well dressed that everybody looked at him, was once said to Beau Brummell. "Then he was not well dressed" was Brummell's rejoinder. The truth is that excess either way slovenliness on the one hand or a "petit-maitre" fastidiousness on the other argues a defect of judgment not reassuring to the patient often full of morbid fancies or misgivings and seldom in a mood to be charitable. The medieval school of Salerno is even more explicit on medical demeanour and apparel than the Roman Hippocrates. In addition to the "kindly look" it counsels the 'good coat' and does not object to the "handsome ring on the finger as evidence of means or of some patient's gratitude.

Clemens accedat medicus cum veste polita.

Lucent in digitis splendida gemma sulis.

(Let the physician approach, bland of demeanour and in dress à la

mode let a brilliant of pure water sparkle on his fingers.) Nor according to the same authority ought his means of locomotion to be out of keeping with his dress.

Si flecti valeat, quadrupes sibi sit pretiosus
Ejus et ornatus splendidus at quo de ena.

(If possible let him have a horse of value and let its equipment be bright and in good taste.) Besides impressing his clients favourably it will be his endeavour to win its goodwill—

Ornatu nitido conabere carior casa.

(With a handsome turn-out you will try to be better liked—if indeed, carior does not admit of another rendering in the sense of gaining higher fees.) This latter interpretation seems implied in the second line of the distich—

Splendidus ornatus plurima dona dabit.

(A magnificent turn-out will yield the largest honoraria.) The effects of a disregard of 'externals' are given in another distich—

Villiter indutus munus sibi vilo parabit
Nam pauper medicus villa dona capit

(Shabbily dressed the practitioner will earn for himself a shabby fee, for if poor his receipts are correspondingly so.) These 'wise saws' of the Salernitan school point to the fact that its alumni were more than the monastic practitioners who attended the sick or disabled as part of their religious duties. They included the fashionable or the court physician practising in high places. It was, indeed, for a Norman king that, in the first instance, Salerno compiled its medical rules.

"THE FUND FOR THE RELIEF OF THE WIDOW OF THE LATE MR. H. KINGSLEY HUNTER, L.S.A."

To the Editors of THE LANCET

SIRS—I beg to announce the receipt of the undermentioned donations to this fund, making a total of £72 7s 3d.

I am, Sirs, yours faithfully,

RIVERS WILSON, Treasurer

Mr Percy Sharp	0 10 8	Mr Walter H. Dodd	1 1 0

Dakta Sahib—We do not see that there will be any benefit to the profession at large gained by the publication of the correspondence in question. It is unfortunate that Dr R. resented our correspondent's action through a misapprehension. It is also unfortunate that our correspondent was not informed of the facts contained in Dr R.'s second letter. The matter seems to us to be one which both gentlemen should at once agree to forget.

J. K.—Our supplements at different times have touched upon the growth of hospitals but there is no one supplement which gives the whole story nor do we know any book that contains it. The big London and provincial hospitals have all at one time or another we believe, issued pamphlets containing their histories. For the ancient history of London hospitals our correspondent may consult Stryke's Survey of London and other recognised authorities.

P. D. S.—No such book has been written. The introductory and valedictory addresses of the presidents of various learned societies, ophthalmological, obstetrical &c. often take the form of a review of progress along certain lines. The *Annus Medicus of THE LANCET* gives a résumé of medical and surgical developments during each past year.

E. H. P.—The waters of Levico (Tyrol) are both arsenical and ferruginous and of good repute. There are no arsenical waters known to us in England. The medical man who recommended treatment perhaps knows of a water the properties of which accord with his suggestion.

M.R.C.P.—The address of the Tallerman Institute is 59 Welbeck street. The question concerning fees had better be addressed to the secretary.

lucrative occupation than at present it seems to be. But though water is not fattening the want of it is thinning, for the drought interferes with the appetite and with the solution and assimilation of food. But let not the corpulent too readily resort to a dry diet as a means of reducing their bulk. To limit the water is to limit irrigation and excretion and to favour the accumulation of waste products such as tend to produce gout and other disorders. Treatment by dehydration must therefore be cautiously exercised and never long continued.

ON CONCENTRATED FOODS

I might make a short chapter like that "Concerning Snakes in Iceland" and say that there are no such things. For "human nature's daily food" are required certain weights of nitrogen, carbon, oxygen, and hydrogen which are ultimate forms of matter and not capable of concentration or further reduction to essential principles. An ox cannot be got into a teacup by any other process than by leaving the greater part of the animal outside. The stomach of the average man demands every 24 hours 21 grammes of nitrogen, or about three quarters of an ounce, 307 grammes of carbon, or about 11 ounces, 12 grammes of hydrogen, not quite half an ounce, besides sulphur and salts. This is required to make up for the waste—to restore what leaves his body in various shapes. Three quarters of a pound of carbon cannot be got into less than three quarters of a pound. The nutritive effect cannot be separated from the bulk. The man must have his pound of flesh. He has to find fuel and to replace waste—charcoal to burn and nitrogen for repairs. If he does not get the necessary poundage he will dwindle, peak, and pine. His account of profit and loss must be adjusted according to weight. A drachm of Liebig's extract cannot supply more than a drachm. Quality cannot supply the place of quantity. The chief nourishers of life's feast are not creatin and creatinin but albumin, myosin, fat, gluten, starch, and sugar. None of these are capable of being administered otherwise than in their natural bodies and corporeal bulk. A sick person who is presented with Valentine's food in teaspoonfuls when he should have milk in pints has as much right to complain as I should have if I were to ask for a steak in the luncheon room and be put off with a minute quantity of Liebig out of the shop. I might object that whatever the virtues of the Liebig it was not filling at the price. But we cannot reckon concentrated extracts as entirely useless, though they are not, properly speaking, food. They contain little or no albumin, some little, some none, no fat, and of the vegetable carbohydrates none. They contain salts and extractives which may be accessories to food but are not food itself. Perhaps they may be regarded as complementary or supplementary to the essentials of food and may in special circumstances have special use. I have long been in the habit of using them to help to make up for the loss by suppuration and so prevent or retard the consequent lardacity. So far as pus carries off the salts meat extracts cannot fail to supply the means of replacing them. These extras are, of course, only to be employed as superadditions to a diet abundant in other respects, not as substitutes for any part of it. They cannot take the place of nutriment in bulk. Beside their power of supplying salts and extractives which under special circumstances may be wanting it is supposed that they have some stimulant action. But the utility of concentrated foods has been greatly exaggerated in practice, they are additions to the essential diet, not substitutes for it. It is possible that a pennyworth of milk may be worth more to the patient than a shillingworth of Liebig's extract.

DIET IN TYPHOID FEVER AND THE TYPHOID STATE

To take the general condition first let me say what I mean by the "typhoid state." I mean the advanced condition of prostration, with a dry tongue, a rapid and failing pulse, and usually a high temperature. This is found in a typical state in the later stages of enteric fever, but also in typhus fever, pneumonia, and pyæmia, and often towards the close of phthisis and of many diseases, especially if they be accompanied with fever, which tend to death by exhaustion and cardiac failure. In these conditions, with a morbidly high temperature and failing powers of vitality, we have increased thirst, and the high temperature is at the same time accompanied by diminished ability to assimilate food. Less is

capable of being taken. For these two reasons the body wastes, much is taken out of it, and little is put in. It is so common for us to see these subjects of fever and prostration fed only upon liquids that it may not occur to us to question why they are thus restricted. They want more food than in health, for they are rapidly losing weight—why put them off with less? The dry tongue answers the question. The tongue is dry because no saliva is secreted. I long ago ascertained this by catheterising the salivary ducts. While in ordinary conditions the saliva would drip freely from the cannula with a dry tongue none could be obtained. Under advanced fever and extreme prostration the saliva fails to be secreted and the tongue becomes dry and encrusted. There is much reason to believe that what happens to the salivary glands happens also to other glandular structures concerned in digestion, especially those which produce the gastric juice. If this be so a dry tongue may be taken as a sign of loss of digestive power with which goes loss of appetite. Nature revolts against solids, nor could the stomach deal with them could they be swallowed. What has to be done under such circumstances is to give only liquids or food in solution, which is practically food upon which one part of the digestive process, and that probably the most difficult part, has been accomplished. Dissolved food can be absorbed and utilised with a minimum of digestive effort. If the stomach retains never so little of its function it may suffice to peptonise and adapt for absorption the food which is already dissolved. Perhaps much of it may be taken up by the vessels almost unaltered. This is the roundabout reason for what has long been taught by experience that when the tongue is dry the patient must live by suction.

Now let us consider for a moment of what the liquid food should consist. Milk is complete nutriment, it contains all the essentials. The casein supplies the nitrogenous part, the fat and sugar the carbon. Milk should always be given under such conditions as I am considering. Eggs, again, in their totality, yolks and whites together, may be regarded as complete nutriment. Out of one the entire animal is constructed—bone and fibre, muscle, fat, and nerve. Eggs in their entirety can sometimes be given beaten up with milk or otherwise, but the whole egg is less constantly available than the yolk with certain additions. The white is coagulated by alcohol and therefore cannot form part of the smooth, palatable, and digestible compound known to druggists as "mistura spiritus vini Gallici" and to the public as "egg flip." This, as I shall presently show, is especially useful as complementary to beef tea since it contains exactly what beef tea wants. But I will put the "mistura" on the shelf for a moment while I say a word about beef tea.

Beef tea takes the next place to milk in the accepted dietary of the typhoid state. It is wholly of the nitrogenous class though not wholly or chiefly consisting of nitrogen. It contains the animal extracts of which Liebig's extract may be taken as the type. It contains, or ought to contain, gelatin abundantly, it contains no albumin in a liquid form, but should have a fine sediment into the composition of which coagulated albumin enters. It contains no fat or only a trace. Thus, beef tea, though greatly superior to the concentrated extracts, is wanting in carbonaceous materials. It yields only as much of them as can be obtained by the breaking up of the nitrogenous compounds. It is worth while to consider for a moment how much carbon or carbohydrate can be got in this way. A good deal but not enough. Whether we take the proteid bodies as represented by albumin, or gelatin which largely enters into beef tea, both these nitrogenous bodies contain carbon in a much larger amount than nitrogen. Albumin contains 53 per cent of carbon and 15 per cent of nitrogen, gelatin contains 50 per cent of carbon and 18 per cent of nitrogen. We may put it roughly that the most nitrogenous components of our food contain three times as much carbon as nitrogen. The amount of carbohydrate which is wrapped up in albumin is manifested in diabetes when sugar is abundantly made out of a diet which consists as strictly as possible of foods of the nitrogenous class. In such a case the albumin is broken in two, one fragment being angric the other urea. I mention this to illustrate the fact that nitrogenous food necessarily includes much of the carbonaceous. But it does not include enough, for the maintenance of the body 14 times as much carbon is required as nitrogen. To take albumin as the type of nitrogenous food this contains scarcely four times as much carbon as

DIET IN INTESTINAL OBSTRUCTION

[illegible]

poultices to the chest over a pneumonic lung and valued themselves in being up to date and rather enlightened than not. The practice, as I have had occasional opportunity of observing, still lingers in remote places. Let us consider what a poultice is. It is something wet and warm which makes the surface to which it is applied sodden and soft and facilitates the efforts of the pus corpuscles to break through the walls of their prison house. In dealing with a subcutaneous focus of inflammation this may do good. But how about the lung? The wet cannot reach it, the linseed cannot project its salutary moisture across the pleural cavity. The warmth, if warmth be wanted, can be more conveniently applied. Whatever sense there may be in keeping the chest warm by means of coverings which are light, dry, and not such as to require frequent change, I can discern only the want of sense in embarrassing the patient with sloppy nuisances which interfere with his comfort, exhaust him by frequent lifting and changing and the special effect of which cannot possibly reach the organ they are designed to benefit. For my part I always recommend a light jacket of cotton wool as the best application to the chest in pneumonia—not that this does more good than any other light and warm clothing, but that it gives satisfaction as something special to the disease and keeps off things that might be more open to objection. No doubt practitioners of medicine have been led to the misuse of poultices by an analogy the fallacy of which is obvious. A poultice does good to a superficial abscess therefore it is good for inflammation in general and cannot fail to benefit a hepatized lung or a region of bronchitis.

Local bleeding often affords another instance of the want of thought with which local remedies are aimed at disorders inaccessible to them. The hypochondrium has been leeched to deplete the liver, the chest leeched or cupped to deplete the lung, the scalp or the nape of the neck leeched or cupped to drain the brain, the loins cupped to influence the kidney, and the scrotum leeched to relieve the testicle. What can be more unreasonable when one comes to think of it than leech

g the hypochondrium to deplete the liver seeing that here is no direct vascular connexion between the two? There is no communication between the superficial vessels of the hypochondrium and the vessels of the organ beneath excepting what is trifling and roundabout. It is easy at a post mortem examination to place the hand between the wall of the abdomen and the front of the liver and realise by touch the extent of the separation between them. The hepatic artery and the portal vein which supply the liver may be regarded as practically independent of the vessels of the abdominal wall. Similarly with regard to the testicle the scrotum derives its blood from the femoral and iliac arteries, the testicle from the aorta. With regard to some of these practices there is enough excuse to found an argument upon in a debating society, but with none is there enough to demonstrate their utility. It is true that certain minute vessels make a connexion between the capsule of the kidney and the lumbar structures but it is equally true that so overwhelming a proportion of the renal blood is drawn by the renal artery directly from the aorta, that any attempt to lessen this supply by drawing upon the circulation of the skin would be about as rational as trying to lower the water at London Bridge by taking some out of the Serpentine. Similar reasoning may apply to the brain and the scalp. There are some communications, but scarcely enough to warrant the attempt to relieve the one by way of the other. Yet how often have we seen the temples leeched at the expense of the external carotid when the territory of the internal carotid is in question. If we wish to deplete the lung, the liver, or the brain it must be by way of the general circulation whether by venesection or otherwise. Superficial measures are suited to superficial disorders. Their obvious utility in such circumstances has done much to magnify their efficacy and to promote their employment where they can but be useless. In regard to serous cavities and joints these have their outer walls for the most part, connected by numerous anastomoses with the covering skin. The outer layers of pleura and pericardium and the capsules of the knee and other joints can be depleted from without to their frequent advantage, but not so can the deeper and unconnected structures be influenced. The relief in leeching the chest for pleurisy or pericarditis is often obvious, equally so is the withdrawal of serum by vesication from a rheumatic joint. But there must be a community of circulation between the surface operated on and the structure aimed at. But far beyond local blood letting the great abuse and

opprobrium of superficial therapeutics has been what is called "counter irritation." We know of "irritation," a thing to be generally avoided, but is there such a thing as "counter irritation"? Can we do good to one part by doing harm to another? Can we fetch out the virus of a deep disease by opposing to it superficial attractions? The old counter irritators either did not know their anatomy or did not regard it, between the skin and the lung is a great gulf fixed, nor is the base of the brain within obvious reach of the nape of the neck.

It is not my purpose now to deal at length with a subject which I have more fully discussed elsewhere, but I may briefly advert to some of the practices which are more honoured in the breach than the observance. The actual cautery to the epigastrium for ulcer of the stomach is one of them. I have been told by a physician who witnessed it in bygone days and in a foreign country that one mode of treating cholera was to apply suddenly to the abdomen an instrument like a spade which had just been immersed in scalding water. If the patient yelled the restoration of his voice was regarded as of good omen. I remember the time when a person with a cerebral lesion, whether meningitis, apoplexy, or tumour, was almost sure to be blistered on the nape of the neck and was exposed to the chance of having the sore kept open by means of savine ointment. One physician, by way of being in advance of his time, treated diabetes in this way, for, thought he, diabetes is a disease of the medulla oblongata and the nearest skin is that of the neck. It will be observed that in the theory which inspired this treatment of cerebral disease, or disease supposed to be cerebral, there is no consideration of the course of vessels or nerves or of the interposition of cavities. The vulgar belief in external applications is displayed in the popularity of many nostrums. In old days there was St. John Long's liniment as a cure for phthisis, an abominable mixture of turpentine and acetic acid which we could wish had been freely applied to the quack who invented it. More recently orthodox practitioners have put irritants to the chest for tubercle of the lung. I remember being taken about 40 years ago by an eminent and honoured surgeon to see a case of phthisis. We made a division of labour. I localised the tubercle in the apices, and he with the most conscientious care cut two blisters exactly to fit the lesions. I stood by consenting. We acted according to our lights. I suppose we had a vague notion of drawing something out or setting up a superficial disorder which should compete with and detract from the deeper. But now the bacillus has to be reckoned with. Neither can this make its way out by the surface nor can its multiplication in the lung be supposed to be affected by anything we can do to the skin. Similar criticisms apply to the painting of the surface with iodine, which is not only applied uselessly in phthisis but in many other conditions. Iodine upon the cuticle is, I believe, not absorbed, at least I have not been able to find any trace in the urine when it has been thus applied. I am a total disbeliever in the sorbifacient action of iodine when used externally whatever it may do when introduced internally. I believe that the painting of enlarged glands is always useless and generally injurious for it tends to set up irritation which is of all things to be avoided. I have already alluded to the utility of vesication when applied within the vascular territory of a serous effusion. Fluid within the pleura, the pericardium, or the knee may be thus removed or lessened, but not by iodine. I have more than once experimented on two knees belonging to the same person similarly affected with serous effusion. One has been repeatedly blistered and the other painted with iodine, the blistered joint has always shown the greater diminution, the subject of the iodine none or not more than might be attributed to nature. I can recall the time when everyone with bronchitis had his chest rubbed with some irritant, generally ammoniacal. If we wish to apply local remedies to the bronchial tubes it can only be by inhalation, placed upon the skin we fail to discern any mode by which their influence can be projected upon the remote and disconnected mucous membrane. Superstitions die hard. Not long ago an eminent physician was called to a distant city to see a child with double pneumonia. Two blisters, together covering a large part of the chest, were comprised in the treatment. Let us hope that the rest of it was more rational and more comforting. The public naturally put faith in local treatment. If the disease can be localised what can be more

THE DIAGNOSIS OF CERTAIN NOTIFIABLE DISEASES

BY F ROORD CIVIEL M.D., M.B.C. Lond.

READ AT A MEETING OF THE LANCET SOCIETY, JULY 17, 1893.

The accurate and early diagnosis of infective diseases is of the greatest importance in general practice, if only in view of the importance of early isolation, but in the days of compulsory notification it assumes an exaggerated importance. I shall therefore attempt at the best of my ability to give a brief summary of the relative value of the various symptoms in the diagnosis of some of the more important infectious diseases. I have become impressed as the result of 12 years' daily observation that it would be impossible to establish limits of a short paper to deal individually with each of the diseases which are now so generally notified. I have therefore adopted a different method, and have grouped the diseases into three classes, according to the importance of the symptoms in the diagnosis of each. The first class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The second class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The third class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain.

The accurate and early diagnosis of infective diseases is of the greatest importance in general practice, if only in view of the importance of early isolation, but in the days of compulsory notification it assumes an exaggerated importance. I shall therefore attempt at the best of my ability to give a brief summary of the relative value of the various symptoms in the diagnosis of some of the more important infectious diseases. I have become impressed as the result of 12 years' daily observation that it would be impossible to establish limits of a short paper to deal individually with each of the diseases which are now so generally notified. I have therefore adopted a different method, and have grouped the diseases into three classes, according to the importance of the symptoms in the diagnosis of each. The first class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The second class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The third class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain.

A paper read before the South-West London Medical Society on May 13, 1893.

The accurate and early diagnosis of infective diseases is of the greatest importance in general practice, if only in view of the importance of early isolation, but in the days of compulsory notification it assumes an exaggerated importance. I shall therefore attempt at the best of my ability to give a brief summary of the relative value of the various symptoms in the diagnosis of some of the more important infectious diseases. I have become impressed as the result of 12 years' daily observation that it would be impossible to establish limits of a short paper to deal individually with each of the diseases which are now so generally notified. I have therefore adopted a different method, and have grouped the diseases into three classes, according to the importance of the symptoms in the diagnosis of each. The first class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The second class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain. The third class includes those diseases in which the symptoms are so characteristic that the diagnosis is almost certain.

the disease. At the earliest stage as soon as the tension of the skin associated with the inflammatory hyperæmia of the rash has subsided, on careful inspection the most superficial cuticular layer will be found to present a number of small perforations of about the size of a pin's head or larger which give to it a "worm eaten" appearance, each of the "pinholes" corresponding to one of the finely papular constituents of the recent eruption of which the delicate investing layer has become rubbed off. During the next few days each of these little "pinholes" or rings becomes gradually larger by centrifugal extension until its periphery becomes merged with those which have spread from other and neighbouring centres. As a result anything suggesting this ring like arrangement then becomes indistinguishable and more or less triangular islets or shreds of cuticle remain, which are ultimately shed, thereby completing the desquamative process so far as that portion of the surface is concerned. The early stage of the peeling, then, is characterised by this "pinhole" appearance of the cuticle and the later stage by these "islets" or irregular shreds of epidermis which are the last to separate. This peculiarity yields trustworthy evidence as to the peeling being scarlatinal, and, moreover, according to its progress, and the parts of the surface which have become invaded, valuable indications may be derived as to the length of time which has elapsed since the commencement of the attack. Lastly, from the confirmatory evidence which is often afforded by the *supervention of one of the well recognised complications of scarlet fever*, chief of which are, of course, otorrhœa, cervical adenitis, nephritis, and rheumatism. There are certain facts connected with the appearance of these complications which are well worth remembering when one is concerned with their value as confirmatory evidence of scarlet fever. The otorrhœa, for instance, is practically limited to young children, its percentage incidence falling progressively from 18.5 in the first quinquennium of life to 0.7 in the fourth quinquennium. The cervical adenitis shows a progressive fall from 11.7 in the first quinquennium to 1.4 in the fourth. Renal inflammation, as evidenced by either acute nephritis or simple albuminuria, remains pretty constant at all ages, though definite acute nephritis is relatively rare after 15 years of age. Scarlatinal rheumatism, on the other hand, becomes more frequent as age advances, its incidence rising from 0.4 per cent under five years to 13.6 per cent in persons aged 20 years and upwards. Another striking point in connexion with the rheumatism is a remarkable constancy in the time of its appearance—viz., almost invariably the fifth, sixth, or seventh day of the attack, at a time when the rash and fever in simple scarlet fever are just disappearing.

These, then, are the main indications on which we rely for the diagnosis of scarlet fever. A well developed attack should present no difficulty, and there is really no excuse for mistaking it for any other disease. But the case may be very different. It is the ill developed or negative attacks which so often give rise to very great difficulty and constitute the *dilemma* of the general practitioner who is but too often expected to be endowed with intuitive perception—the kind of attack which causes one to ask oneself, "Is there sufficient evidence in this case to justify the diagnosis of scarlet fever?" "Must I insist upon a prolonged and often, both to the patient and his friends, an irksome period of isolation which may possibly be, after all, unnecessary?" Or, on the other hand, "Am I justified in letting this patient remain where he is with the ultimate possibility of disaster?" It must be confessed that in some cases the question is unanswerable by any human observer, but I think that if cases are carefully tested by the criteria which I have enumerated their number will not be very considerable.

Now, turning to the differential diagnosis of scarlet fever it may, I think, be fairly stated that there are two classes of ailments with which scarlet fever is most liable to be confounded. First, those in which sore throat is the prominent feature—viz., simple tonsillitis, diphtheria, and certain cases of influenza, and secondly, those which are attended with a diffused red exanthem—viz., measles, röteln, and a condition resulting from the administration of certain drugs. Now the differentiation of simple tonsillitis from mild scarlet fever may be an extremely difficult thing, especially in adults, in whom the sore throat is often accompanied by a distinct rosy efflorescence on the skin. This, however, is usually limited to the chest and the abdomen, perhaps invading the arms as well, but it is rarely seen on

the legs. It lacks the punctate character which is so distinctive of the scarlatinal eruption, being represented by a simple erythematous flush, which, though often vivid at an early stage, rarely persists for more than from 24 to 36 hours and leaves no staining of the skin behind. There is probably an absence of prodromal vomiting and the tongue retains the character which is almost invariably associated with tonsillitis. It is pale and flabby in appearance and is coated with dirty white pasty fur, so different to the rapidly cleaning tongue of scarlet fever. This distinction is most important, as there is no form of sore throat other than that associated with scarlet fever which is attended with a clean, much less a raw, tongue. Frequent careful and minute inspection of the skin will fail to reveal any indication of peeling, except perhaps on that portion of the neck which has been previously covered with a poultice or a hot fomentation, but even here there is an absence of any "pinhole" arrangement. In an adult or older child the occurrence of rheumatic pains and tenderness in any of the joints, especially in the wrists or the metacarpophalangeal joints from five to seven days after the onset of a febrile sore-throat of doubtful nature, is strongly indicative of the case being one of scarlet fever, and the same inference attaches to the appearance of otorrhœa in a young child though not perhaps appearing until two or three weeks later. Simple albuminuria is as common during the febrile stage of simple tonsillitis as it is in scarlet fever, but the supervention of either simple albuminuria or acute nephritis during the second, third, or fourth week is strongly in favour of the latter. Simple tonsillitis but very rarely occurs in young children. In them a definite inflammation of the faucial structures, except as part of a general catarrh, almost invariably means one of two diseases—viz., scarlet fever or diphtheria.

The differentiation of scarlet fever from diphtheria is often confused owing to the fact not being sufficiently well recognised that an exudation is occasionally present on the tonsils in scarlet fever, which is certainly not diphtheritic. The exudation of scarlet fever, which was, I think, first described by Professor Henoch under the name of "scharlach nekrose," is only found in cases attended with severe faucial inflammation. It is limited to one or both tonsils and does not encroach either on the palate or the uvula. It is more cheesy and friable in consistence and never presents the glistening or fibrous appearance which is so often seen in true diphtheria. Further and more general points in the differentiation between scarlet fever and faucial diphtheria will be referred to when dealing with the latter disease.

The fact that tonsillar or faucial inflammation is occasionally the most obvious manifestation of certain attacks of influenza is responsible for its being sometimes mistaken for scarlet fever, and it is probably within the experience of many practitioners that a whole series of attacks of this protean disease at one time or another have conformed to this type and so contributed to the confusion, at any rate at an early period of the epidemic. The absence of a punctiform eruption and of early cleaning of the tongue, the irregularity of the temperature, the intensity of the prostration, and the relative immunity of young children are points which tend to exclude scarlet fever.

Now, in respect to the eruptive diseases which most frequently simulate scarlet fever—viz., measles and röteln (or German measles)—the latter is the one which is most often a source of difficulty, the reason being that both rash and sore throat are normal accompaniments of röteln. The differentiation from scarlet fever is sometimes exceedingly difficult. The points on which reliance must be placed are the following: 1. A longer period of incubation, usually 10 days or rather more. 2. An absence of prodromal vomiting and actual pain in swallowing. 3. The rash is usually the first sign, indeed, it may be the only sign, of illness. 4. The temperature is frequently normal throughout and is rarely raised for more than from 24 to 48 hours. 5. The eruption is usually mealy at an early stage, though the spots are usually pinker, smaller, and more discrete than in true measles. At a later stage, usually by the second day, the eruption tends to become erythematous on the trunk, when no suggestion of individual spots can be made out, and this is the time when its likeness to scarlet fever is most confusing. Unlike scarlet fever, however, definite spots are to be seen on the face in most cases, though rarely visible there for more than from 36 to 48 hours. The eruption generally will in all probability have disappeared, even from the legs, by the end of

The first of these is the fact that the results of the experiments are not in agreement with the results of the experiments of other workers. The second is the fact that the results of the experiments are not in agreement with the results of the experiments of other workers. The third is the fact that the results of the experiments are not in agreement with the results of the experiments of other workers.

Having now briefly alluded to the disabilities which attach to the discharge of a soldier from the service, I will now proceed to consider the various means by which the soldier may be enabled to obtain a discharge from the service, and the various means by which the soldier may be enabled to obtain a discharge from the service.

[illegible]

The first of these is the fact that the law is not a static body of rules, but a living organism which grows and changes with the times. The second is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The third is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The fourth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The fifth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The sixth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The seventh is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The eighth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The ninth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen. The tenth is the fact that the law is not a mere collection of rules, but a system of principles which guide the conduct of the citizen.

207. Of the drugs which may simulate the eruption of scarlet fever are copalva, salicylic acid, acetylsalicylic acid, and iodoform. The rash resembling that of scarlet fever has been in each case a false one, although in the case of copalva and belladonna there may be a distinct suggestion of pseudotuberculosis. The general aspect of the eruption, coupled with careful inquiry into the history and the absence of any signs of scarlet fever, should make its recognition pretty certain.

[illegible]

material from the throat and the other some inspissated blood serum, preferably Löffler's preparation, on which the material is sown by simply rubbing its surface with the swab. These tubes can be procured at very small cost from the Jenner Institute, the Clinical Research Society, Messrs Burroughs, Wellcome, and Co., and other druggists of repute, and as they will keep for months in a cool place two or three of them may be kept for immediate use should occasion arise.

In the differential diagnosis of faucial diphtheria it is mainly in connexion with follicular tonsillitis and the exudation throats present in some cases of scarlet fever that difficulty is most often experienced. From follicular tonsillitis the differentiation may be most difficult, and, indeed, it may be impossible apart from the bacteriological test. The distinction is rendered none the less difficult owing to the fact that in some cases of diphtheria the exudation commences at the very points which are most characteristic of follicular tonsillitis—viz., at the mouths of the follicular crypts in the form of spots or little patches of exudate which at a later stage enlarge and ultimately become confluent so as to form a continuous pellicle covering the surface of the tonsil, but at an early stage the appearance of both is very similar. The clinical features on which some reliance can be placed are that in follicular tonsillitis the spots rarely coalesce and the exudation never spreads to adjacent parts but remains limited to the tonsils. Both tonsils are usually affected very much to the same degree and the same thing holds good for the swelling of the subjacent glands, while in diphtheria it is perhaps more common for one side to be involved more than the other and for the gland swelling to be proportionally greater. In follicular tonsillitis albuminuria is far less common, but the temperature is usually higher—in fact the general statement is justified that the constitutional disturbance in follicular tonsillitis is likely to be more pronounced than in a case of diphtheria of sufficient mildness to be mistaken for it. It should be remembered, too, that in a child the attack is more likely, *prima facie*, to be one of diphtheria than of tonsillitis simply because in childhood the latter disease is relatively uncommon. Laryngeal implication never supervenes, nor does any subsequent paralytic affection, whether of the palate, accommodation, or of the skeletal muscles—so distinctive of diphtheria.

Now, of those cases of scarlet fever which are attended with an exudation simulating the appearance of diphtheria it may be stated generally that they are almost invariably severe attacks and the characteristic symptoms of scarlet fever are usually so pronounced that the presence of that disease can hardly be overlooked. The difficulty in this instance is usually to decide whether the exudation is purely scarlatinal or whether, as is sometimes the case, it is an attack of scarlet fever complicated with coexistent diphtheria. The scarlatinal exudation is limited to the tonsils practically always, it is of a cheesy, friable consistence and it is easily removed with a camel hair brush, tending to disappear spontaneously in a day or two. If it be genuine diphtheria, on the other hand, it is usually thicker, tough, gelatinous, or fibrous looking, incapable of removal without lacerating the subjacent tissue, and it separates *en masse* after an interval of several days. In a case of uncomplicated diphtheria, of course, the exudate may be thin, friable, and easily detached, but in these concurrent attacks the condition is usually grave and the exudation as a rule presents the characters which I have mentioned. The constitutional depression, too, is severe and the case is very liable to terminate fatally with cardiac failure or to present some form of paralysis during early convalescence. As far as my experience goes it is much more common for a case of diphtheria attended with an erythematous flush to be mistaken for scarlet fever than for a case of scarlet fever with exudation to be confused with diphtheria.

In laryngeal diphtheria or membranous croup the differential diagnosis from simple laryngeal catarrh may be very difficult during the early stage, and this is particularly so when the larynx is the primary seat of the disease. It is very fallacious to place any reliance on a history of exposure to cold or on the apparent absence of any source of infection. Nor can any trustworthy indication be derived from the character of the respiration or the quality of the cough or laryngeal sound. I know of no other reliable test than a bacteriological examination of some of the laryngeal mucus which can be easily obtained by passing a swab mounted on

a bent wire into the upper part of the larynx. But this, of course, means the loss of valuable time unless the diagnosis can be made by means of an immediate microscopical examination of the material on the swab, which is usually possible to anyone conversant with the diphtheria bacillus and which in most cases will prove reliable. The fact that "cases of simple catarrhal laryngitis are never fatal" is not of much assistance in the early diagnosis of the condition. In cases, however, in which the fauces are involved primarily or even coincidentally with the larynx—a condition which is of common occurrence—there is not much room for doubt. The appearance of the very smallest patch of exudation on the tonsil in a case of croup is practically sufficient to establish it as one of laryngeal diphtheria and calls for prompt and efficient treatment. This is above all the class of case for showing what a splendid weapon we possess in antitoxin.

Enteric fever.—Let us now turn our attention to enteric fever, a disease of which the diagnosis is liable to be attended with more difficulty probably than in the case of any other specific fever. There are several reasons why this should be so. 1 In its clinical appearances it so often simulates some other disease. 2 There is frequently a complete absence of any symptoms referable to the abdomen, consequently a diagnosis can only be arrived at in many cases by a process of exclusion. 3 It is very prone to become complicated by some other disorder, particularly bronchitis, pneumonia, and alcoholism, of which the symptoms are liable to be so prominent as to obscure the ordinary manifestations of enteric fever. 4 Lastly, the indications suggesting the presence of enteric fever may not be apparent until the lapse of a week or more, and, having in the meantime formed a different opinion as to the nature of the attack, we are liable to be hampered in our diagnosis by the influence of a preconceived idea.

In most cases of enteric fever the development of the attack is undoubtedly slow and insidious, but by no means necessarily so. I have met with a good many cases of enteric fever in which the onset was as sudden and explosive as in any case of small pox or influenza and these cases almost invariably run a severe course. During the first week of enteric fever, in addition to the usual complaint of headache, weariness, aching of the back and limbs, progressive loss of appetite, coating of the tongue, vague pains in the abdomen, and increasing pyrexia, there are four symptoms which are very suggestive of oncoming enteric fever, though not often mentioned, as far as I remember, in the text-books—viz., slight bronchial cough, sore throat, partial deafness, and bad dreams. A patient will frequently admit upon being interrogated that he has slept badly, often during the night waking suddenly with a start in consequence of some transient nightmare which he has probably quite forgotten in the morning until it is recalled to his mind by a leading question. On inquiry into the history of the onset it will usually be elicited that there have been short periods of intermittent diarrhoea, rarely of longer duration than a day or two, which may or may not reappear during the progress of the fever. The fact cannot be too strongly emphasised that diarrhoea is by no means a necessary attendant of enteric fever. If 100 consecutive attacks of all grades of severity be taken it will be found that, in this country at any rate, the large proportion (if we except the slight premonitory diarrhoea referred to) are characterised by constipation throughout and require the routine soap and water enema every third day. If however the severe attacks alone be taken the majority will be found to have been attended by diarrhoea of the usual pea soup character.

Of the other characteristic indications of enteric fever a few words must suffice. The typical daily remittent temperature declines gradually during defervescence. A termination by crisis hardly ever occurs in enteric fever unless the case has been complicated, usually by pneumonia. This may affect a small patch of lung simply and not necessarily an entire lobe. It will have been sufficient to delay the normal defervescence of temperature which would otherwise have taken place, but when the pneumonic crisis occurs the temperature falls suddenly, since the enteric fever may no longer be able to provide for its further sustentation. A slow pulse is occasionally met with, the rate at no time rising above from 44 to 60 beats although the temperature may have ranged from 101° to 103° F. for a considerable time. These "slow pulse" cases in my experience have always done well, though Murchison seems to have regarded them as of unfavourable omen. The eruption is

never seen before about the end of the first week, but specimens were common at that time. The first birds conveyed to me were collected on the twenty of the month, as it does in Cyprus for about 30 to 40 per cent of the cases are attributed by a rash and the large majority of these are in children. One cannot expect to find positive evidence of enlargement of the spleen until the end of the week and the enlargement can rarely be detected later than two or three days after the temperature has begun to fall. Personally, I am very sceptical as to any probability for recognising enlargement of the spleen in enteric fever with certainty unless I can feel the lower border beneath the costal arch. I have often seen the observation as to the absence of enlargement discounted in the post-mortem room. Obvious enlargement occurs in from 30 to 40 per cent of enteric fever convalescents. It is for the most part limited to the trunk, is scaly, and is more, I believe, of the "pin hole" variety.

infections which I have encountered some degree of mental impairment of a regular daily feminine character rarely showing any period of complete involution and still the type, rarely affecting the limbs and still more rarely the paralytic to the fingers 5 A positive reaction with the Wassermann test 6 The onset of intestinal hemorrhage or perforation at a later stage

The appearance of epidemic influenza during the last 10 years has greatly increased our difficulties. There are some characteristics of this epidemic which I will delay any human observer to differentiate from epidemic fever at an earlier stage, that is unless he may have seen very little of the difference between typhus fever and of the same importance in this country as it was 25 years ago when the disease occurs in London, as it occasionally does even now, the earlier cases are usually mistakably for enteric fever, especially in children, in whom the rash is often absent

The following is a list of the names of the persons who have been appointed to the various committees of the Board of Directors of the City of New York, for the year 1901:

SUPERANNUATION ALLOWANCE—Dr Richard Wellgate medical officer of the First District Wells (somerset) Union, has been granted a superannuation allowance of about £70 by the Wells Board of Guardians

PHYSICAL DIAGNOSIS IN THE INSANE

BY JAMES F GEMMEL, M B, O M GLASG,
ASSISTANT MEDICAL OFFICER TO THE COUNTY ASYLUM LANCASTER

NOWHERE perhaps is the importance of physical diagnosis more forcibly presented to our minds than in the insane. In them we have much more frequently than, not it alone to depend upon, and the aid which the general practitioner and hospital physician obtain subjectively, together with the history, is usually wanting or at best unreliable. This of itself is a great disadvantage and we would be grateful were it the only one, for another which the asylum physician has frequently to encounter is the resistance of the patient to examination. Only those who have experienced it know what this really means. The maniacal shouts, turnings, and twistings, to say nothing of more determined efforts to oppose, are circumstances not calculated to facilitate examination. Yet such we have frequently to contend against, not only in diagnosing disease in this class of patient but in treating it. Catheterism, for example, has often to be performed and wounds dressed in patients assuming the most inconvenient postures. Another drawback, the insensitiveness of the insane, from whatever cause arising, to bodily pain and discomfort, is sufficiently well known. The numerous instances of retention of urine suspected by the practised eye from perhaps a change in posture or an alteration in walk, strangulated hernia uncomplained of and discovered on bathing or on attention being called to an attack of vomiting, enteric fever recognised when the eruption is out, and numerous other examples of serious bodily disease to which no attention has ever been directed by the patient himself, are experiences which we have all met with. Hence it is that apparently very trivial circumstances may often give warning and indicate to our eyes grave illness. Notwithstanding, however, the keenest observation we have every now and then disease presented to us in a stage which in sane patients would have been complained of at the outset and have thus afforded an earlier opportunity of diagnosis or at all events an approximate one. For the detection, then, of disease in the insane we have to rely almost entirely upon physical diagnosis. With these preliminary remarks I propose to mention and briefly describe a few cases by way of illustration, some of them interesting from their comparative rarity and all with one exception from the fact that the history and symptomatology were for practical purposes wanting.

Purulent meningitis—The patient in this case was a woman, aged 21 years. Beyond the fact that she was known to have a mitral regurgitant murmur there was nothing in her past history having any bearing on her present ailment, of which the patient was quite incapable of giving any account. She had for a few days previously to Sept 28th, 1898, not been taking her food as well as usual and as she looked generally ill on that morning she was at once sent to the hospital. Her temperature then was 103° F. She gave no indication that she could hear what was said to her, was semi-conscious, and could scarcely be roused. Her muscular system was in a state of extreme irritability and on being raised for purposes of examination she became very stiff and rigid, the head was drawn back, and the muscles of the back of the neck were thrown into a state of tetanic contraction. The pupils were dilated and reacted sluggishly, the gums were spongy and suppurated from decayed teeth, the tongue was dry and coated, and the urine was normal. Nothing was discoverable in the lungs or abdominal organs to account for her condition. Her temperature in the evening rose, to 105° and since admission frequent retching and vomiting had supervened. On the 30th the temperature still continued high (104°), vomiting, irrespectively of the state of the stomach as to food, was persistent, the bowels were confined, there was retention of urine, the pupils were still dilated, the tongue was dry and foul and the lips and gums were covered with sordes. The muscular system was extremely irritable and the patient became rigid on any attempt at movement. The pulse was rapid but regular and the respirations were correspondingly increased. There was a dark trophic patch on each buttock. The patient was quite unconscious. On Oct 1st the temperature was 104.8°, the specific gravity of the urine was 1030, it was albuminous, and contained a trace of sugar, the

head and eyes deviated to the right, the mouth was slightly twisted to the same side, and there was slight facial twitching. The right arm was rigidly flexed and when forcibly extended and let go at once resumed its abnormal position. The eyes were suffused. There were dark trophic areas and bulge on the heels and tarsal prominences. On the 2nd the patient was comatose and rapidly sinking. She died on the evening of the 3rd, the temperature rising to 105.8° some hours before death.

Necropsy—The dura mater was thickened and firmly adherent to the skull cap. The pia arachnoid over the convex and basal aspects of the brain was thickened and infiltrated with a greenish yellow exudation of pus dipping down between the sulci and specially thick and abundant in the track of the larger fissures. The surface and lateral margins of the cerebellum were also invaded. Generally the brain substance was soft and cedematous and the vessels were congested. The grey matter was of a deeper colour than usual. The ventricles were dilated and filled with a dirty yellow fluid. There were hypertrophy of the left ventricle and thickening of the mitral valve. The kidneys were congested and the left one exhibited several recent infarcts.

Phlegmonous gastritis—A man, aged 66 years, on Dec 22nd, 1898, complained of nausea and vomiting. There was nothing, however, in his general appearance to indicate that there was anything very much the matter. His temperature was normal but the pulse was somewhat irregular. The next morning he rose but fell back and suddenly expired.

Necropsy—The heart was found to be enlarged, weighing 14 ounces, the mitral valve was stenosed and the aortic valve was calcareous and incompetent. The stomach was greatly dilated, the mucous membrane was congested, and submucous hemorrhages were present. The stomach wall was greatly thickened and on section large quantities of fluid pus exuded from the submucosa which was in a state of diffuse purulent infiltration.

Malignant endocarditis verrucosa—No detailed description of this case which lasted about three weeks will be entered upon, but only a general survey of its progress from commencement to finish along with the factors contributing to its differential diagnosis. The only clear history obtainable was that some months previously the patient had a severe attack of rheumatic fever from which she slowly recovered, but with an impaired mental condition which gradually becoming more pronounced culminated before admission in an attack of acute delirium. Her condition on admission was one of semi-consciousness, extreme restlessness, incoherent muttering and screaming, loss of control over the sphincters, constant purposeless movements of the limbs and body, and extreme motor irritability. In fact, at first sight the case appeared to be one of severe and fatal chorea which is occasionally to be met with. That there were some grounds for the suspicion I think may not very strongly be objected to. The patient sometimes refused food, but this was not owing to inability to swallow, as the act of deglutition was normally performed even when the general muscular system was in a state of violent movement, the patient tossing her arms and legs about and rolling her head uneasily from side to side. These choreiform movements would suddenly cease and the patient drop into apparently a deep slumber from which, however, she was easily roused. The skin was hot and dry and later exhibited a petechial rash, the tongue and lips were parched and covered with sordes, the pupils were dilated and her general appearance indicated some acute, febrile affection. The temperature was 103° F on the evening of admission and continued more or less elevated throughout, though exhibiting considerable irregularity. The urine contained a large quantity of albumin and there was a loud mitral regurgitant murmur, considerable diarrhoea, slight distension of the abdomen, and gurgling were also present from the beginning. No rose spots or enlargement of the spleen were ever detected. Towards the end the heart's action became extremely rapid, the albumin increased, and coma supervened. Throughout muscular irritability was extreme and any attempt at sitting the patient up was accompanied by tetanic rigidity of the erector spinae muscles. Passive motion of the extremities yielded the same state of matters.

Necropsy—The heart weighed eight ounces. Large warty vegetations were present on the mitral segments and surrounding the mitral orifice. The left kidney and spleen were the seat of infarctions and both the kidneys were cirrhotic.

obstruction in the insane is often discovered so late that for all practical purposes the symptoms would seem to indicate the acute form. No history is obtainable and the earlier symptoms which among the sane would lead one to suspect chronic obstruction have never been complained of by the patient or noticed by the attendant. Vomiting, collapse, and most probably tympanites may, as already suggested, be the indications that first direct attention to the patient. Such is the case presented, what is it? For purposes of limitation I assume that the case is one of intestinal obstruction and the only other condition provocative of somewhat similar symptoms from which it will be attempted to distinguish it is perforation with accompanying peritonitis. In differentiating the various forms of obstruction too much stress must not be laid on the age of the patient, for although an age of 45 years and upwards is suspicious of volvulus or stricture it does not by any means exclude strangulation by bands, &c. With this reservation, then, and taking for granted that the obstruction of the small bowel has been excluded and that the patient's age, &c., suggest volvulus or stricture, I shall discuss only these two causes of obstruction. If the case is seen comparatively early—i.e., before the abdomen is excessively distended—the appearance of fullness extending from the left hypogastric and iliac regions towards the umbilicus, together with a feeling of increased resistance and tension communicated to the hand and a development of hyperresonance in this locality point to volvulus. If upon these signs supervene an increase in the horizontal diameter of the abdomen and of the resonant area of the colon the diagnosis is rendered still more certain. The passage of a long tube or digital examination under chloroform will also tend to confirm. In what way, however, may volvulus be distinguished from stricture of the sigmoid? I am still presuming a case in which the patient is admitted to the hospital with vomiting, distension, collapse, and with no history. The passage of a long tube only reveals the fact that there is an obstruction in the lower portion of the gut and for differential purposes digital exploration is more valuable. If by means of it an irregular hard mass or enlarged glands are felt, the presence of malignant stricture, especially if the left leg and thigh are swollen and the veins are engorged, is practically confirmed. If, however, the stricture lies in the upper portion of the sigmoid, or beyond, digital examination or that by the tube affords little or no information and other features of the case have to be considered in order to arrive at any satisfactory conclusion. In volvulus, again, constipation is absolute from the first, but in stricture, especially malignant stricture, there is often diarrhoea and discharge of blood. Further, in stricture the contour of the colon is better defined and dulness and the feeling of a semi-fluid or mouldable mass limited to the region of the caecum or extending thence in the line of the ascending colon is more significant of this form of obstruction than of volvulus as in the latter these signs are to a considerable extent obscured by the production of gas in a voluminous sigmoid and the lesser likelihood of faecal accumulation owing to more persistent vomiting. To the presence of the same may also be attributed the infrequency of coils and visible movement of the intestine in volvulus as compared with stricture. The excessive accumulation of faeces in stricture is owing to the prolonged previous constipation and to the fact that food is not vomited to the same extent as in volvulus, in which the accumulation if it exists is in the sigmoid and may when this is very moveable even be the cause of the volvulus. Under certain conditions the vomit in stricture may consist almost entirely of blood and that in large quantities. When such is the case stricture may be mistaken for perforation of a gastric ulcer or *vice versa*. In perforation there may or may not be hæmatemesis, but if owing to rapid collapse attention is drawn and the patient seen before distension of the abdomen from peritonitis has set in, we can, from what has already been said on the subject of stricture, affirm pretty confidently that it at least is not present. If, however, the patient comes under observation after peritonitis has set in the diagnosis is rendered more difficult and the probability of ascertaining the state of the colon by palpation is rendered almost impossible by the rigidity of the abdominal walls and great peritonitic distension. The age of the patient and the progress of the case will then be our chief guides. Gastric ulcer occurs at a much earlier age than stricture and when perforation occurs tends to a

more rapidly fatal issue. It is of course obvious that profuse hæmatemesis due to stricture of the colon can only occur when the obstruction is malignant and has become adherent to the wall of the stomach.

Lancaster

ON "CHRONIC VENEREAL SORES," OR "ULCERATING GRANULOMA," WITH AN ILLUSTRATIVE CASE

By J MAITLAND, M D EDIN,
LIEUTENANT-COLONEL, I M S. PROFESSOR OF MATERIA MEDICA AT THE
MADRAS MEDICAL COLLEGE. SURGEON TO THE MADRAS
GENERAL HOSPITAL.

With Note by JAMES GALLOWAY, M D ABERD,
F R O P LOND

THE following case affords a typical example of the disease described by myself in the *Indian Medical Gazette* of May, 1898, under the designation of "chronic venereal sores" and which appears to be identical with the affection prevalent in British Guiana and named by Dr J H Conyers and Dr O W Daniels' "groin ulceration." At the time that the above mentioned article in the *Indian Medical Gazette* was written I had not had the advantage of seeing the description of the disease given by Dr Conyers and Dr Daniels and I was unaware that any notice of it had previously been published. The disease is fairly common in Southern India, and Surgeon Colonel K Macleod's article on the subject in the *Journal of Tropical Medicine* for February, 1899, points to the fact that it is also to be found in Northern India. The following are the notes of the case.

A Hindoo cigar roller, aged 30 years, was admitted into the Madras General Hospital on Feb 14th, 1899, suffering from sores in the groin and on the penis. The history given by the patient was as follows. Six months previously, four days after intercourse, a sore appeared on the glans penis. Ten days later a bubo formed in the right groin, burst, and discharged sanious fluid. Neither the ulcer on the penis nor the bubo ever healed but continued to spread slowly up to the date of admission into hospital. Slight local pain and irritation were experienced but the general health was not affected in any way. The following note was made of the condition of the patient on admission to hospital. "The patient is well developed muscular, and in good health. Situated in the right groin is a sore measuring two and a half inches in length by one inch in width. There is no induration of the base of the sore which can be freely moved to and fro over the underlying structures. The surface, which is raised above the level of the surrounding skin in some places to the extent of a quarter of an inch or more, is irregular, of a dirty pink colour, and somewhat waxy appearance. In consistence it is soft but firm and hairs are seen protruding here and there from the surface. It is almost entirely devoid of discharge. The edges are fairly regular and show no signs either of healing or breaking down. A small zone of epidermis is seen to mount, as it were, into the base of the mass of granulation tissue. Close to the existing sore is the scar of an old bubo. The prepuce is retracted and swollen. Situated on the under surface of the glans and body of the penis is a sore which differs in some respects from the one already described. The surface is smoother and not raised much above the level of the surrounding skin and scattered over it are numerous small white patches of newly formed epithelium. A slightly offensive odour is given off from the sores." On admission to hospital the following treatment was resorted to. The skin surrounding the sore in the groin was shaved and thoroughly purified by means of antiseptic lotions and boric acid dressings were applied. A month after admission an anæsthetic was administered and the whole of the affected skin in the groin together with some of the underlying fat and lymphatic glands were removed by means of the knife. The edges of the resulting wound were then brought together by sutures. It was considered advisable to postpone operation upon the penis until the wound in the groin was healed. Five days later, slight pain being complained of, the dressings were removed, when it was found that suppuration had taken place and two stitches were removed to give exit to the pus.

[illegible]

is furnished by the results of the operation of erosion. In the scrofulous operation all the granulation tissue is thoroughly scraped away and the resulting wound is cauterised with a strong paste of white healing action followed by numerous applications of new epithelium springing up in various directions on the surface of the sore. In respect of this peculiarity and also in the appearance of the sore in its early stages "the affection presents a remarkable resemblance to 'jaws'." So much is this the case that it would be difficult to distinguish the one from the other did the diagnosis rest on the sores themselves. In jaws, as is well known, the lesions of the surface and may be distributed over the whole surface of the body and not confined to one particular region, as in the case of this disease. Moreover, the sores never attain the same size in jaws as they do in the other affection. Dr Gallois¹ states that there is a close histological resemblance between the two diseases. In many of the cases cited by Dr Cooper and Dr Daniells the disease appears to have been complicated by an elephantoid condition of the affected region and Colonel Bramford, M.B., who has met with a considerable number of cases of similar complication in many of the patients who have come under his observation. There is no reason to believe, however, that such a condition is anything more than an accidental complication. In no case which has come under my observation has there been any changes resembling those seen in elephantiasis. In regard to the incidence of the disease our experience in India coincides with that of surgeons in British Guiana. The disease appears to be confined to young adults or middle-aged persons and to be limited to the coloured races. In the matter of treatment also there appears to be a coincidence of opinion between medical men in the two countries. The disease is seldom if ever influenced by any constitutional treatment or by the effects of any local application. Thorough removal of the soft tissue by means of a sharp spoon followed by the application of Vienna paste to the firm and bony-looking structures beneath, is sometimes followed by apparent cure, especially when the sore is limited to the region of the groin. Complete excision of the sore is more effective but cannot be effected in many instances. When the penis is implicated and the disease is of long standing amputation through healthy tissue should be performed.

NOTE BY DR JAMES GALLOIS — Lieutenant Colonel Valland, M.B., has been good enough to send me portions removed from the patient whose case is described in this paper. The skin presents histological changes agreeing with those which I have already described in detail in the *British Journal of Dermatology*.² The portion of skin examined is in a later stage of the disease than the specimen from which my illustrations were drawn. The implication in the cutis is very dense and consists of cells of the same type as those described. The striking feature is the great masses of "plasma cells" and the absence of ordinary macrocytes. The skin is present in the connective tissue is present transforming the cutis and breaking up the new cell infiltration into separate masses. There is almost no tendency to liquefaction or any rapid degeneration in these the nuclei are fragmented and debris of chromatin granules is plentiful. Throughout the cutis the vessels are much dilated and in the lower part this change is so great as to simulate certain of the cutaneous angiomata. In the deeper layers of the skin and subcutaneous glands are seen to be present with apparently healthy epithelium, some have undergone cystic dilatation. The epididymis of the surface is very thin and atrophied, but numerous peg-like processes of epithelium project down into the transformed cutis and possess apparently healthy epithelial cells. These are the relics of the long interstitial processes of epithelium which form so striking a feature in the early stage of the disease. The observations on these tissues corroborate the conclusions previously arrived at, 2. Lenticular Granuloma of the Prepuce (Inverted) British Journal of Dermatology vol. LV. p. 133, 1891. 1 Loc. cit.

that the disease is a chronic "infective granuloma" quite distinct from syphilis and tuberculosis, presenting certain histological peculiarities recalling the structure of frambœsia (yaws) but differing from this disease in its clinical course and general anatomical features and distribution. There can be no doubt that the disease described by Lieutenant-Colonel Maitland and Surgeon Colonel K Macleod in India is identical with the "groun ulceration" described by Dr Conyers and Dr Daniels in British Guiana
Madras.

SOME CASES OF MALIGNANT DISEASE ASSOCIATED WITH OVARIAN TUMOURS.

By JOHN D MALCOLM, M.B., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, MARLBOROUGH ROAD W.

In this paper I propose to record very briefly some cases of malignant disease associated with ovarian tumours. By "malignant disease" I mean either (1) that the tumours have been examined by competent microscopists and have been declared to be malignant in structure (carcinomatous or sarcomatous), or (2) that in addition to ovarian tumours growths have been found in the liver, peritoneum, or other organs when an operation has been performed, or (3) that such growths have developed later and have brought about the death of the patient. In most cases these secondary growths have been examined and found to be of malignant structure, but in some cases there has been no post-mortem examination. When I state the microscopic appearances of a tumour I do so on the authority of Mr Targett or of Mr Corrie Keep and I have to express my thanks to these gentlemen for permission to use their names.

It seems to me that the possibility of an ovarian tumour being malignant is not kept before the profession so prominently as its importance deserves. A large number of papers on ovariectomy are devoted to statistics of mortality, to showing how very easy and satisfactory the operation is, and to proving that the death rate is very low. When these are the objects aimed at the papers may be published so soon after the patients have been operated upon that in a large proportion of the cases there has not been time for secondary growths to develop and, moreover, in discussing the mortality of an operation it is not necessary to bring forward other disagreeable sequelæ. Statistics having scientific value are most difficult to collect and on the question of malignancy in ovarian tumours it is almost impossible to obtain reliable figures. The number of cases which cannot be traced, the number of cases in which the cause of death is not verified by conclusive clinical or post-mortem evidence, and the long time which may elapse between the removal of a tumour and the development of malignant disease are difficulties which can hardly be completely overcome. The question requires many years of careful clinical and pathological work, every tumour being thoroughly investigated and every case being kept under observation for a long period—till death if possible—before even an approximate estimate of the percentage of malignant cases can be obtained. I regret that I have not paid special attention to this subject for more than a few years, its enormous importance having been gradually forced upon my attention. I therefore do not propose to record any statistics of my own. The following instances, are, however, sufficient to prove conclusively that in a number of cases the relationship between an ovarian tumour and malignancy is very intimate.

CASE 1.—On May 8th, 1888, I assisted Mr Knowsley Thornton to remove a rapidly growing, very multilocular cystic ovarian tumour from a woman, aged 42 years. The growth was adherent to everything it touched. The uterus and left ovary were healthy. Mr Thornton in his notes of the case wrote that the tumour "might be malignant." Three and a half months later (on August 23rd) I opened this patient's abdomen on account of obstruction of the bowels and I found several small round growths of from the size of a pea downwards and a mass of about the size of a Tangerine orange implicating two coils of small intestine. I was informed that this patient's father had died from

cancer of the gullet at the age of 68 years. The father's sister had died from a cancer and his mother had died from a tumour. The case is already published in full.¹

CASE 2.—I have published² another case in which I performed an easy ovariectomy on June 6th, 1893, the patient's age being 35 years. There were a few slight pelvic adhesions and I noted that there was a small piece of solid tissue in the base of the tumour. The patient had no trouble for more than two years after the operation. She then became very constipated and this difficulty increased rapidly. On Jan 28th, 1896, I explored the abdomen, the bowel being then almost completely occluded. There were numerous growths studded over the peritoneum and large masses on the under surface of the liver. I made an intestinal fistula which gave temporary relief. A great aunt of this patient was said to have had cancer of the breast.

CASE 3.—On Oct 8th, 1895, I saw a patient, 47 years of age, from whom Dr Pregaldino of Ghent had removed a tumour of the right ovary which, he kindly informed me, was an adeno carcinoma. The patient recovered from the operation quickly, put on flesh, and felt very well until a short time before I saw her when she began to suffer from pelvic pains and a vaginal discharge. She had the appearance of being in excellent health. I found a tumour on the left side of the uterus, rising above the pelvic brim, involving the cervix and fungating into the vagina. It seemed to me to be semi cystic. It extended so far into the tissues on the left side of the pelvis that complete removal was impossible. The patient died nine months later.

CASE 4.—On Aug 16th, 1892, I saw a patient with Mr Crew of Higham Ferrers. She was 25 years of age and was supposed to be quite well on July 30th when she left her home on a visit to friends. She had noticed an enlargement of the body before this but had not spoken of it. On August 1st she was seized with severe pain in the abdomen and on the 11th a medical man said that she was so ill that she could not travel. It was, however, very desirable that she should go home and Mr Crew therefore had her moved on the 12th. On the 16th she was very anæmic with a hectic temperature, profuse perspiration, and an extremely feeble and rapid pulse. There was a very tender pelvic swelling rising nearly to the level of the umbilicus. An opinion had been given that the swelling was a large abscess. I thought that it was most probably an ovarian tumour with a twisted pedicle, or possibly an inflamed dermoid ovarian tumour. If nothing were done the patient's death was certain, so I advised that the abdomen should be opened, although the conditions were most unfavourable for such treatment. On operating I found two ovarian tumours, each solid throughout, but they were both so soft that they broke up under the fingers and had to be removed piecemeal. There were extensive adhesions and much thickened omentum was cut away. The tissue of the broad ligaments was fairly firm where I tied them. After the operation the patient passed through a period of extreme feebleness, but I was able to send her a good nurse and under Mr Crew's guidance a gradual improvement took place. The temperature was normal 12 days after the operation and the strength very slowly increased till November when she began to lose ground. I saw her on Nov 17th. She then had a swelling in the right side of the pelvis which was very difficult to define on account of great intestinal distension. The breathing was rapid and there was a slightly impaired percussion note over the base of the left lung. No further symptoms developed and the patient died on the 24th. There was no post-mortem examination. The tumours were not examined microscopically, but I have no doubt that they were malignant and that infection had already passed beyond their margins before I operated.

CASE 5.—On Oct 14th, 1892, I removed a multilocular ovarian tumour from a woman 60 years of age. The tumour contained much solid tissue and was firmly adherent to the anterior abdominal wall. I saw this patient eight months later and she was then dying with large masses of hard growth in her liver.

CASE 6.—On March 1st, 1892, I removed a tumour³ which had every appearance of a simple ovarian cyst and contained no solid tissue except the cyst wall. This tumour was not adherent anywhere. The patient had also malignant disease

¹ THE LANCET July 18th, 1891 p. 113.

² Twenty-six cases in which an abdominal section has been performed a second time. Case No. 7 Transactions of the Medical Society vol. xx.

the head of the patient. Her father's sister had died

Case 7.—Early in June, 1893, a patient was admitted

Child with an ovarian tumour. She had been tapped

month before. I saw her and again three weeks later. I

very broad base. I had to divide the uterus in the middle

all the primary growths might have been cured but

the ovarian tumours and uterus and I therefore did not think

it right to do more than the double ovariectomy. The

months later.

Case 16.—I operated on Jan 14th, 1895, in another case

in which the uterus was removed with the ovaries. The left

the broad base, but secured otherwise free. The right

there were many adhesions on this side. A coil of intestine

was adherent to and firmly stretched over the front of the

tumour, the adhesions to it being thick and fleshy. I began

to separate this coil, and in doing so exposed a piece of

intestine into which a hard mass was growing from the

tumour. This could not have been separated without a

resection of the gut, and as there were many extensive

adhesions behind and probably other resections would have

been required. I did not think it justifiable to perform an

operation. I have not been able to trace her subsequent

history.

Such cases as this last one never, so far as I am aware, get

into the statistics of ovariectomy, but these extraordinary ex-

ceptions on ovarian tumours are very important. Whether from a

scientific point of view or simply as a guide to the surgeon by

a patient who is told that she has an ovarian cystoma. The

omission of such cases as this and the custom of putting the

statistics of cases in separate lists or omitting them also from

the statistics of the mortality of the operation.

run by a patient with an ovarian neoplasm.

There is another and still more difficult question to the ques-

tion of malignancy in ovarian tumours. There can, I think,

be no doubt that a complete and early removal of a can-

cerous growth—for as much as a century of the breast—does

sometimes effect a permanent cure. There is no organ which

can be more completely removed than an ovary which has

developed a tumour, and very many ovarian tumours have

under such circumstances it would not be

extraordinary if a tumour should be surgically and essen-

ually malignant and yet should not return after removal.

It is sometimes said that an ovarian tumour rarely simply

this may be so and in others the appearances might be

considered as due to a dilatation of follicles together with

a hypertrophy of the cyst walls. But in a large number

of ovarian tumours there is an obvious development of new

run by a patient with an ovarian neoplasm.

There is another and still more difficult question to the ques-

tion of malignancy in ovarian tumours. There can, I think,

be no doubt that a complete and early removal of a can-

cerous growth—for as much as a century of the breast—does

sometimes effect a permanent cure. There is no organ which

can be more completely removed than an ovary which has

developed a tumour, and very many ovarian tumours have

under such circumstances it would not be

extraordinary if a tumour should be surgically and essen-

ually malignant and yet should not return after removal.

It is sometimes said that an ovarian tumour rarely simply

this may be so and in others the appearances might be

considered as due to a dilatation of follicles together with

a hypertrophy of the cyst walls. But in a large number

of ovarian tumours there is an obvious development of new

tissue which is of an adenomatous or papillomatous type

from the naked-eye appearances whether a tumour of the ovary

is malignant or not. Under the microscope adenomatous

next growth is frequently found and this does not seem to

tend to spread beyond the ovary or to recur when removed.

In describing the structure of adenocarcinoma Mr. Morton

Baker and Mr. Bowley state that in these tumours the

issues may be found arranged after the manner of a

simple tubular gland, and also "after the manner of a

typical carcinomatous structure and the adenomatous growth

scirrhous cancer." They add that "between the latter

all intermediate steps may be readily traced." In his book

described as malignant adenoma." From the foregoing it

seems to me that in the ovary there is no absolutely definite

separation possible at present between innocent and malig-

nant tumours, whether they are looked at from the stand-

point of the surgeon or from that of the microscopist. I have

for a short time endeavoured to get a report on the micro-

scopic characters of every tumour which I have operated on,

died and it was found that the new tissue had infiltrated the

tumour. The rectum was opened in doing so. The patient

surface of the growth. I divided this and shelled out the

ligament which was tightly stretched across the upper

pelvis. It was held down by an enormous hypertrophied

pedicular ovarian tumour which was firmly fixed in the

SOME CASES OF MALIGNANT DISEASE ASSOCIATED WITH OVARIAN TUMOURS.

By JOHN D. MALCOLM, M.B., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND
CHILDREN, MARLBOROUGH ROAD W.

In this paper I propose to record very briefly some cases of malignant disease associated with ovarian tumours. By "malignant disease" I mean either (1) that the tumours have been examined by competent microscopists and have been declared to be malignant in structure (carcinomatous or sarcomatous), or (2) that in addition to ovarian tumours growths have been found in the liver, peritoneum, or other organs when an operation has been performed, or (3) that such growths have developed later and have brought about the death of the patient. In most cases these secondary growths have been examined and found to be of malignant structure, but in some cases there has been no post-mortem examination. When I state the microscopic appearances of a tumour I do so on the authority of Mr. Targett or of Mr. Corrie Keep and I have to express my thanks to these gentlemen for permission to use their names.

It seems to me that the possibility of an ovarian tumour being malignant is not kept before the profession so prominently as its importance deserves. A large number of papers on ovariectomy are devoted to statistics of mortality, to showing how very easy and satisfactory the operation is, and to proving that the death rate is very low. When these are the objects aimed at the papers may be published so soon after the patients have been operated upon that in a large proportion of the cases there has not been time for secondary growths to develop and, moreover, in discussing the mortality of an operation it is not necessary to bring forward other disagreeable sequelæ. Statistics having scientific value are most difficult to collect and on the question of malignancy in ovarian tumours it is almost impossible to obtain reliable figures. The number of cases which cannot be traced, the number of cases in which the cause of death is not verified by conclusive clinical or post-mortem evidence, and the long time which may elapse between the removal of a tumour and the development of malignant disease are difficulties which can hardly be completely overcome. The question requires many years of careful clinical and pathological work, every tumour being thoroughly investigated and every case being kept under observation for a long period—till death if possible—before even an approximate estimate of the percentage of malignant cases can be obtained. I regret that I have not paid special attention to this subject for more than a few years, its enormous importance having been gradually forced upon my attention. I therefore do not propose to record any statistics of my own. The following instances, are, however, sufficient to prove conclusively that in a number of cases the relationship between an ovarian tumour and malignancy is very intimate.

CASE 1.—On May 8th, 1888, I assisted Mr. Knowsley Thornton to remove a rapidly growing, very multilocular cystic ovarian tumour from a woman, aged 42 years. The growth was adherent to everything it touched. The uterus and left ovary were healthy. Mr. Thornton in his notes of the case wrote that the tumour "might be malignant." Three and a half months later (on August 23rd) I opened this patient's abdomen on account of obstruction of the bowels and I found several small round growths of from the size of a pea downwards and a mass of about the size of a Tangerine orange implicating two coils of small intestine. I was informed that this patient's father had died from

cancer of the gullet at the age of 68 years. The father's sister had died from a cancer and his mother had died from a tumour. The case is already published in full.*

CASE 2.—I have published* another case in which I performed an easy ovariectomy on June 6th, 1893, the patient, age being 35 years. There were a few slight pelvic adhesions and I noted that there was a small piece of solid tissue in the base of the tumour. The patient had no trouble for more than two years after the operation. She then became very constipated and this difficulty increased rapidly. On Jan. 28th, 1896, I explored the abdomen, the bowel being then almost completely occluded. There were numerous growths studded over the peritoneum and large masses on the under surface of the liver. I made an intestinal fistula which gave temporary relief. A great aunt of this patient was said to have had cancer of the breast.

CASE 3.—On Oct. 8th, 1895, I saw a patient, 47 years of age, from whom Dr. Pregaldino of Ghent had removed a tumour of the right ovary which, he kindly informed me, was an adenocarcinoma. The patient recovered from the operation quickly, put on flesh, and felt very well until a short time before I saw her when she began to suffer from pelvic pains and a vaginal discharge. She had the appearance of being in excellent health. I found a tumour on the left side of the uterus, rising above the pelvic brim, involving the cervix and fungating into the vagina. It seemed to me to be semi-cystic. It extended so far into the tissues on the left side of the pelvis that complete removal was impossible. The patient died nine months later.

CASE 4.—On Aug. 16th, 1892, I saw a patient with Mr. Crew of Higham Ferrers. She was 25 years of age and was supposed to be quite well on July 30th when she left her home on a visit to friends. She had noticed an enlargement of the body before this but had not spoken of it. On August 1st she was seized with severe pain in the abdomen and on the 11th a medical man said that she was so ill that she could not travel. It was, however, very desirable that she should go home and Mr. Crew therefore had her moved on the 12th. On the 16th she was very anæmic with a hectic temperature, profuse perspiration, and an extremely feeble and rapid pulse. There was a very tender pelvic swelling rising nearly to the level of the umbilicus. An opinion had been given that the swelling was a large abscess. I thought that it was most probably an ovarian tumour with a twisted pedicle, or possibly an inflamed dermoid ovarian tumour. If nothing were done the patient's death was certain, so I advised that the abdomen should be opened, although the conditions were most unfavourable for such treatment. On operating I found two ovarian tumours, each solid throughout, but they were both so soft that they broke up under the fingers and had to be removed piecemeal. There were extensive adhesions and much thickened omentum was cut away. The tissue of the broad ligaments was fairly firm where I tied them. After the operation the patient passed through a period of extreme feebleness, but I was able to send her a good nurse and under Mr. Crew's guidance a gradual improvement took place. The temperature was normal 12 days after the operation and the strength very slowly increased till November when she began to lose ground. I saw her on Nov. 17th. She then had a swelling in the right side of the pelvis which was very difficult to define on account of great intestinal distension. The breathing was rapid and there was a slightly impaired percussion note over the base of the left lung. No further symptoms developed and the patient died on the 24th. There was no post-mortem examination. The tumours were not examined microscopically, but I have no doubt that they were malignant and that infection had already passed beyond their margins before I operated.

CASE 5.—On Oct. 14th, 1892, I removed a multilocular ovarian tumour from a woman 60 years of age. The tumour contained much solid tissue and was firmly adherent to the anterior abdominal wall. I saw this patient eight months later and she was then dying with large masses of hard growth in her liver.

CASE 6.—On March 1st, 1892, I removed a tumour* which had every appearance of a simple ovarian cyst and contained no solid tissue except the cyst wall. This tumour was not adherent anywhere. The patient had also malignant disease

* THE LANCET July 18th 1891, p. 113.

* THE LANCET Sept. 8th, 1894 p. 573.

and I hope that in this way interesting information may be obtained. I feel sure that every tumour should be examined. The case above recorded of an apparently simple ovarian tumour and cancer of the head of the pancreas would seem to indicate that even the most innocent looking tumours of the ovary may be associated with cancerous formations. I do not discuss the question of the possibility that the ovarian tumour and the cancer may be independent phenomena occurring coincidentally. The points which I wish to emphasise are that ovarian tumours are malignant in a considerable number of cases and that the gradations from innocent to malignant tumours are so insensible that it is not always easy, and perhaps not always possible, to separate them definitely.

A consideration of the foregoing cases leads to one conclusion so obvious that it might almost be considered unnecessary to state it—viz., that the removal of an ovarian tumour should be advised whenever its existence is diagnosed. This is undoubtedly the proper course to pursue and yet I sometimes see cases in which the existence of an ovarian tumour has been recognised for months or years and operation has been delayed until urgent symptoms have arisen. The dangers of the formation of adhesions, of twisting of the pedicle, of the occurrence of pregnancy, of the development of suppuration, &c., should urge the surgeon to immediate action. But of all the arguments in favour of early operation the possibility that the tumour may be malignant, or that it may become malignant, seems to me to be the most forcible and urgent and at the same time the least considered.

Portman street W

ON THE DANGER OF HIGH ALTITUDES FOR PATIENTS AFFECTED WITH ARTERIO-SCLEROSIS

By TH. FINDLATER ZANGGER, M.D.,

LATE ASSISTANT PHYSICIAN, UNIVERSITY HOSPITAL, ZÜRICH.

WE are living in days when the struggle of life and therefore the strain on our nerve power grow more and more intense. To counteract these detrimental conditions changes of scene and air at seaside and Alpine health resorts have to play their part and no one better than the weary practitioner can estimate the value of even a couple of days' rest thus indicated as a necessity to prevent a breakdown. But the practice of patients going up to Alpine heights without medical advice has its grave dangers which year by year come more clearly to my view and into which a long practice at Alpine health resorts has given me a good insight. The public are careless, almost reckless, in this matter, they often disregard judicious medical advice, with the result that serious or even irreparable damage may be done, and sometimes death ensues—a catastrophe easy to be predicted by a careful family physician.

The public, and sometimes the inexperienced physician—in experienced not in general therapeutics but in the physiological effects of altitude on a weak heart—make light of a danger they cannot understand. But if an altitude of from 4000 to 5000 feet above the sea level puts a certain amount of strain on a normal heart and by a rise of the blood pressure indirectly also on the small peripheral arteries, must not this action be multiplied in the case of a heart suffering from even an early stage of myocarditis or in the case of arteries with thickened or even calcified walls?

It is especially the rapidity of the change from one altitude to another with differences of from 3000 to 4000 feet which must be considered. There is a call made on the contractibility of the small arteries on the one hand and on the amount of muscular force of the heart on the other hand, and if the structures in question cannot respond to this call rupture of an artery or dilatation of the heart may ensue. In the case of a normal condition of the circulatory organs little harm is done beyond some transient discomfort, such as dizziness, buzzing in the ears, palpitation, general malaise, and this often only in the case of people totally unaccustomed to high altitudes. For such it is desirable to take the high altitude by degrees, in two or three stages, say first stage 1500 feet, second stage from 2500 to 3000 feet, and third stage from 4000 to

6000 feet, with a stay of one or two days at the intermediate places. The stay at the health resort will be shortened, it is true, but the patient will derive more benefit. On the return journey one short stay at one intermediate place will suffice. Even a fairly strong heart will not stand an overstrain in the first days spent at a high altitude. A Dutch lady, about 40 years of age, who had spent a lifetime in the lowlands, came directly up to Adelboden (altitude 4600 feet). After two days she went on an excursion with a party up to an Alp 7000 feet high, making the ascent quite slowly in four hours. Sudden heart syncope ensued, which lasted the best part of an hour, though I chanced to be near and could give assistance, which was urgently needed. The patient recovered, but derived no benefit from a fortnight's stay, and had to return to the low ground the worse for her trip and her inconsiderate enterprise.

Patients between the ages of 45 and 70 years who are the subjects of arterio sclerosis can often stand altitudes of 4000 feet and higher, this depends on the degree of the sclerotic process and especially on the localisation, though patients in advanced stages all do better at altitudes of not over 3000 feet, and the reason is fairly simple. Take Engelberg, for instance, which corresponds to this height, it is obvious that the patient will want to go for walks and that not only on level paths. He will soon get to altitudes of from 4000 to 5000 feet, even if warned to keep from climbing, sent to a place already 4000 feet high he will take walks to 5000 and 6000 feet and damage may ensue, for if a company one cannot always choose the pace one wishes. I have had patients with arterio sclerosis coming year after year to Adelboden (4600 feet) and only after four or five years symptoms would ensue, and I was obliged, not actually send the patients away, but to confine them to the level walks. In a couple of years the same patients will have chosen an altitude not above 3000 feet if they are to derive benefit. The question must in each case be answered separately and only general rules can be laid down. Patients with arterio sclerosis should not attempt a residence at a high altitude without medical advice. The family medical attendant is the best judge of the possibility, danger, but sometimes nothing short of a trial will decide and the patient must be put under the care of a medical man at the health resort in question.

In any case the patient should take medical advice. Symptoms show themselves, such as sleeplessness, dyspepsia, giddiness, buzzing in the ears, palpitation, paræsthesia, shortness of breath, or definite slight angina pectoris. I have to decide the question in Zürich the altitude of the place (1400 feet) comes to my assistance and by letting the patient ascend the hills around up to 3000 feet, combined with an examination of the blood pressure by means of the Riva-Rocci sphygmomanometer, I can arrive at a safe opinion on the advisability of a stay above an altitude of 3000 feet. Rapid ascents to a high altitude are very injurious to patients with arterio sclerosis and the mountain railways to 7000 feet and 10,000 feet are positively dangerous to the unsuspecting public, for many persons between the ages of 55 and 70 years consider themselves to be hale and healthy and are quite unconscious of having advanced arterio sclerosis and perchance contracted kidneys. An American gentleman, aged 58 years, was under my care for slight symptoms of angina pectoris pointing to sclerosis of the coronary arteries. A two-months' course of treatment in Zürich with massage, baths, and proper exercise and diet did away with all the symptoms. I saw him by chance six months later. "My son is going to St. Moritz (6000 feet) this summer," said he, "may I go with him?" "No, certainly not," was my answer. The patient then consulted a professor who allowed him to go. Circumstances, however, took him for the summer to Sachseln, which is situated at an altitude of only 2000 feet, and he spent a good summer. But he must needs go up the Pilatus by rail (7000 feet) relying on the professor's permission, and the result was disastrous, for he almost died from a violent attack of angina pectoris on the night of his return from the Pilatus and vowed on his return to Zürich to keep under 3000 feet in future.

I may here mention that bad results in the shape of heart collapse, angina pectoris, cardiac asthma, and has not least, apoplexy, often occur only on the return to the lowlands and that patients with cirrhotic kidneys are in the greatest danger. In the case of apoplexy it is generally the combined influence of a few things slight

In one case the external muscles which are stretched in drawing the eyes into line are thin and narrow, yielding readily, in the other they are broad, thick, and tendinous, offering much greater resistance, so the amount of deviation or anatomical defect does not determine the stress or strain. If this evolution of the optic axis was complete there would be no eye strain and the energy now required to sustain it could be utilised in performing other functions more perfectly, thus adding comfort and years to life. How much this strain is, or how much life is shortened and our peace and happiness are disturbed by it, is impossible to calculate, but it must be great from the fact that the nerve centres of vision are so extensive—in fact they are many times greater in area than those which furnish energy for our legs, and the legs may use more than a million foot-pounds of energy in a day.

ON THE EFFECTS OF PRIMULA OBCONICA ON THE SKIN

By ROBERT KIRK, M D EDIN, F F P S GLASG,
PHYSICIAN TO THE DISPENSARY FOR DISEASES OF WOMEN, GLASGOW
WESTERN INFIRMARY.

IN THE LANCET of March 4th, 1899, I recorded a case of myxœdema in which the irritant principle of primula obconica was suspected of having given rise to severe stomatitis and an acute eczematous eruption on the skin. Having now made a few experiments with this plant and having found the results of more interest than I could have anticipated I here propose briefly to notice them.

I first of all began with an experiment on myself by rubbing a small part of the leaf of a primula on the inner aspect of the forearm for a few minutes. No effect ensuing I repeated the process three or four days afterwards, employing more vigorous and prolonged friction. This still remaining without result I rubbed the leaf against the skin on a third occasion by means of a flat bottle containing hot water so as to make sure of breaking up the glandular hairs in which the irritant has been supposed to reside and to increase its effect by the heat if it were a volatile body like toxicodendric acid. Still the result was nil. Becoming now more confident I ventured to apply the leaf on several patients by gentle rubbing but without any result in a single instance. In the course of these experiments I had a visit from the myxœdematous patient whose case was recorded in my former paper and in her presence I rubbed a part of the leaf several inches square against the skin of my forearm for 10 minutes by means of the hot-water bottle as above described. She looked on with astonishment, but said that she would try it once more to convince me. She then took a small part of a primula leaf barely an inch square and with a gloved finger of her right hand rubbed it gently on the inner aspect of her left forearm for not more than a few seconds and then did the same with a few blossoms of the plant on a spot at a little distance remarking that she thought that would do. I should here state that only two days before she had recommenced taking thyroid tabloids after an interval of several weeks during which the use of them had been left off and at the end of which she had swollen perceptibly. Next morning, feeling no effect on myself, I thought no more of the matter until I received a visit from the lady in the evening. I was now surprised to learn that she had not slept since two o'clock in the morning on account of a hot and tingling sensation in the sites of the application and I could scarcely believe the evidence of my senses when I saw that these were the seat of redness and inflammation, this being most marked on the part to which the leaf had been applied, where one border was distinctly raised above the surrounding skin. I applied some bella donna ointment, but the smarting getting worse on the same evening she washed it off, thinking it was doing harm. On the next day I found that the inflammation had subsided a little, but on the following afternoon a crop of vesicles appeared on the site where the blossoms had been applied, although the inflammatory symptoms had throughout been least pronounced there. Some of the vesicles had coalesced and it appeared that if the application had been more prolonged the result would have been a single bulla over the

entire area. I punctured some of the vesicles, when a little thin serum exuded and flowed freely over the arm. I left the patient in the belief that the effects were at an end, but fortunately, although she had not sent for me, I chanced to call upon her a week afterwards when another surprise was in store for me. Both areas were now raw and emitting copiously at various points a thin, pale, watery serum, which showed no tendency to coagulate. She stated that the site of application of the primula blossoms had never ceased to discharge since I had punctured it and that the other surface had risen in blisters two days or so afterwards and had broken and become ulcerated as I now saw it. Both surfaces were itchy and irritable, and she said that she had found the application of very hot water gave her more relief than anything else. The parts healed up a few days later and the patient was positive that this had been mainly due to the applications of hot water which perhaps had tended to coagulate the proteids in the effused serum. They were now covered by a pale brown epidermis resembling a scab, which was interspersed here and there with silvery streaks of whitened scales.

In the course of these observations I had continued experiments upon myself, being convinced that the difference between this patient and other individuals could be only one of degree. Accordingly I next scratched my skin gently as in the operation of vaccination and rubbed a part of the leaf of a primula firmly on by means of a spatula for five minutes and as no effect appeared in two days I repeated the process with several blossoms on the same spot but with out refreshing it. This remaining equally without effect I finally increased the raw area by scratching round its circumference and after rubbing on the flowers as before retained them in position overnight by two strips of adhesive plaster arranged crosswise. On removing these next morning the surface beneath was pale, no doubt from pressure. The same evening I was gratified to find some appearance of inflammation with a sense of heat and itching and next day a few small vesicles actually made their appearance. On puncturing these some serum escaped but not more than a drop or two and it was very different in character from that in the case of the patient whose symptoms I have described, for it was slightly yellowish, viscid, and highly coagulable. On applying some cotton wool and removing it a few hours afterwards I found some fibres of it sticking to the surface which was now practically healed. A scab or two now formed and did not drop off till the tenth day and, what is more interesting, a red areola developed which was at first of a punctate appearance, but gradually became uniform. This continued to spread till the ninth or tenth day and was always itchy, especially at night. It was most marked at parts where it showed most tendency to spread, but was never very severe, so that it was not difficult to resist any desire to scratch. There never was any induration or any elevation of the surface and no constitutional effects were manifested in either of the two cases. I may add that one evening when my arm was itching and I thought the effects had reached a climax, I applied thyroid extract over it with the effect of obtaining almost complete relief after a few minutes' smarting and some considerations lead me to suppose that it would have been a good application to the ulcerated surface in the myxœdematous patient.

A further observation remains to be stated. In my earliest experiments I had one evening applied part of a primula leaf over the pit of the stomach and this also seemed to have no effect, but 10 days afterwards my attention was called to the part by a feeling of tenderness and itching and on inspection it was found to be reddened. It continued red and itchy for two weeks afterwards. Besides this two reddish and itchy spots appeared on the arm not far from the site of application there, to which the irritant had evidently been carried by the movements of the investing sleeve of flannel. It now seemed to me certain that it could not be a chemical compound which had produced these effects on myself and singled out a special constitutional state in such an extraordinary manner as I had just witnessed. Moreover, in the course of the inquiry I had twice made a cold infusion of both the leaves and the blossoms, and found that neither of them yielded to water any free acid whatever, at least any that could be detected by test paper. I could hardly resist the conviction that these effects could only be explained by the action of some germ or micro-organism derived from the plant and I ventured to express this suspicion to two of the pathologists of the Glasgow Western Infirmary to whom I showed my

hospital, it was very distressing and continued to the end. The colour of the vomited material changed from green to brown, there was never any faecal smell and the vomiting could not be stopped. The tongue from start to finish was moist and clean and there was no odour from the breath or sordes. Two days before death hiccough developed. The pulse varied from 60 to 100 and was always strong and of high tension. The temperature gradually rose till the third day when it reached 100°F and afterwards gradually fell to 98.2° on the seventh day and never again rose to normal. The patient's aspect was clear and singularly unlike that of an intestinal case. He was able to move about, was quite clear in his mind, and refused all operative interference, saying that he had always got over similar attacks before. On the evening of the ninth day his pulse suddenly failed and one hour before death he had a convulsive seizure from which he recovered and passed gradually into a comatose condition.

Necropsy—At the post-mortem examination it was found that the abdominal cavity was full of urine, the intestines being congested, especially the sigmoid flexure and the last 10 inches of the ileum. The appendix was perfectly healthy and no constriction of any kind was found throughout the entire length of the alimentary canal. On the fundus of the bladder a perforation was found in the centre of a cicatrix over half an inch in thickness with a second old depressed cicatrix on the mucous surface of the bladder. The aperture had been closed by an adhesion to the sigmoid flexure, as was evidenced by a few remaining adhesions and the corresponding marks on both bladder and gut. The remainder of the bladder was quite healthy.

Remarks by Dr JOYNT and Dr GREEN—The above case is of interest owing to the difficulty of diagnosis. Attention was directed mainly to the symptoms of obstruction which, however, was never absolute, and as the patient had been able to take or retain only a small quantity of fluid and had passed unaided a reasonable quantity of urine no estimation was made of the total quantity of urine which was passed daily. The nature of the vomited material and the patient's aspect and liveliness were not in keeping with anything but a very chronic condition. Undoubtedly the only correct surgical procedure would have been an early laparotomy, but this, unfortunately, was refused. As to the cause of the perforation which was in the centre of an old cicatrix it would be hard to give a definite opinion. The patient had met with two severe abdominal injuries either of which might have caused intra-peritoneal rupture of the bladder, the wound being subsequently closed by adhesion of the sigmoid flexure. Beyond this there was no other sign of old inflammation of the peritoneum which there probably would have been had there been extensive leakage of urine. The patient was on three separate occasions sounded for stone in various hospitals, so that his symptoms must at some time have pointed to calculus, none, however, was found nor was any operation undertaken, and it is most improbable that the bladder was perforated by the injudicious use of instruments. The difficulty of defecation can be explained by the kink in the sigmoid flexure. Possibly over distension of the bladder may have caused the adhesion closing the aperture to give way.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE

A CASE OF ANKYLOSIS OF THE RIGHT TEMPORO-MAXILLARY ARTICULATION, EXCISION OF THE RIGHT CONDYLE, RECOVERY

(Under the care of Mr FREDERICK PAGE)

FIXATION of the lower jaw can be treated either by excision of the condyle or by Esmarch's operation of removal of a wedge of bone from the body of the mandible. Esmarch's operation is more applicable to cases where the fixation is due to cicatricial contraction. Resection of the condyle for bony ankylosis was first performed by Gross of Philadelphia in 1874, though the condyle had been removed 20 years earlier for osteo arthritis. The operation is far from difficult and the only complication which is likely to follow it is paralysis of the facial nerve.

In January, 1898, a young man was sent by Mr R. Taylor Manson of Darlington to the Royal Infirmary, Newcastle on Tyne, suffering from inability to open his

mouth beyond the extent shown in Fig 1. The fixation was due to ankylosis the result of suppurative inflammation of the

FIG 1

right temporo maxillary articulation and the condition was one of great discomfort and inconvenience. The right condyle was excised by a transverse incision when the mouth could at once be fully opened. Fig 2 is a reproduction

FIG 2

of a photograph which was taken eight months after the operation and shows the very satisfactory result which this simple operation gives.

Remarks by Mr PAGE—I believe that excision of the condyle is by far the best method of treating ankylosis of the temporo-maxillary articulation and this is the third case which I have published of a successful result.

DANGEROUS FEEDING BOTTLES.—An inquest was held at Bath on June 7th respecting the death of an infant, aged six months. The mother had taken the child to a medical practitioner and also to the hospital, as she believed the infant had swallowed the regulator on the tube of the feeding bottle. Nothing, however, could be discovered, but two days later the child was admitted into the institution suffering from an obstruction of the larynx. Tracheotomy was performed and the regulator was found firmly fixed in the back of the throat. A verdict of "Accidental death" was returned.

¹ Die Behandlung des narbigen Kieferklemme durch Bildung eines künstlichen Gelenkes um Unterkiefer Kiel, 1860

of the other—that is to say, the heart becomes really hypertrophied. This leads in some way to increased uptake of fluid in the placenta and so to increased exudation by this twin. This increased exudation takes the form of excessive secretion, certainly from the kidneys, probably from the skin, and possibly also from the portion of placenta belonging to the affected foetus, and the accumulation of these discharges leads rapidly to enormous hydramnion of the same foetus. The diagnosis can often be completely made by observing that the signs of a foetus are limited to a small portion of the circumference of a hydramnionic cyst. The appropriate treatment consists in the induction of premature labour by puncture of the membranes. Case 1.—Seventh pregnancy, symptoms beginning at the fourth month, labour induced by puncture of the membranes at five and a half months. The larger foetus was contained in 19 pints of amniotic fluid, with large heart and kidneys and thick umbilical cord with dilated vessels. The smaller twin was in a separate amnion with a normal amount of fluid, the umbilical cord was long, thin, and velamentous, common placenta. Case 2.—Third pregnancy, symptoms beginning at three and a half months, labour spontaneous at five months, enormous gush of fluid followed by birth of twins contained in their membranes. The larger twin was hydramnionic and the smaller one showed marked atrophy of the wall of the left ventricle, common placenta and chorion.

Dr HERBERT SPENCER congratulated Dr Wilson on the full account which he had given of this interesting condition. With reference to the clinical aspect of the subject he (Dr Spencer) had found that ballottement, impossible to obtain in the dorsal position, could readily be got by placing the patient in the knee elbow position when the foetus sank to the dependent part of the abdomen and could be readily felt there. Adverting to the differential diagnosis between hydramnion and an ovarian tumour he suggested in difficult cases the passing of a bougie. He thought that Dr Wilson took somewhat too limited a view of the causation of the hydramnion in these cases. It was evident that the theory given by him would not explain cases of hydramnion in cases of single foetus and according to that theory hydramnion ought to be excessive in cases of acardiac foetus where the circulation of the two foetuses was carried on by the heart of one, this, however, was not the case. He thought that it was a difficult thing to diagnose hypertrophy of the heart in premature foetuses, the size of the viscera varying very much in foetuses of the same size. In one of his own cases of acute hydramnion with homologous twins the foetuses were almost of the same weight (one just over, the other just under, 1 lb 4½ oz) and the hearts appeared to be normal. In this case the cord of the hydramnionic foetus was much twisted near the foetus and oedematous beyond (the placenta and cords weighed 1 lb 7 oz), the oedema thus produced would, he thought, possibly explain the hydramnion in this case, but he did not see how a hypertrophied heart could explain its occurrence. As fluid was found experimentally to exude into the amnion whether injected into the foetal or natural circulation it was possible that hydramnion might arise from abnormalities in either. He agreed with Dr Wilson in regarding the urine as one of the sources of the liquor amnii, if the foetus did not pass urine into the amnion foetal hydro-nephrosis, of which he had seen several examples, would not occur.

Dr A. ROUTH thought that the question of the etiology of hydramnion would not be established without reference to its occurrence in single ova and he did not think that Dr Wilson's theory would explain many of such cases. It did not account for hydramnion occurring in the acardiac twin instead of the hypercardiac, or for the majority of such cases being female and often puny and lacking vitality where the arterial tension must be below normal, or for its frequent occurrence in cases of anencephalus, spina bifida, anophthalmos, &c. He thought the diagnosis by means of uterine contractions most helpful and if abdominal ballottement was obtained over all parts of the abdomen by putting the patient in the knee chest position on either side it proved not only hydramnion but the absence of any complicating ovarian cyst.

Dr GRIFFITH characterised the paper as one of the most valuable contributions to the subject. His own observations had led him to the same conclusions up to a certain point, but he was unable to accept as proved the view that the renal kidneys were sources of liquor amnii. It had never

been demonstrated that it was possible for a foetus to overcome the tension of the liquor amnii and to pass its secretion, if any, into this sac and there was evidence that it could not do so. The determination of such minute quantities of urea or similar substances was difficult.

Dr WILSON, in reply, emphasised the fact that hydramnion, like dropsy and jaundice, was a symptom which might depend on some one or more of a variety of causes. His contribution was intended to deal with one group only of the cases and no attempt had been made to discuss the causes of hydramnion in general. The number of facts in favour of the renal origin of at least part of the liquor amnii left little room for doubting the truth of the theory. Intermittent contractions of the uterus were important in diagnosis. Treatment by rupture of the membranes could only be undertaken when urgent symptoms in the mother demanded it.

The following specimens were exhibited—

Mr MALCOLM 1 Macerated Foetus from Extra Uterine Gestation retained about a year. 2 Macerated Foetus from Extra uterine Gestation retained seven years. 3 Multilocular Tumour growing from the front of the Bladder, containing papilloma and not connected with either ovary.

Dr STEVENS Drawings of Vaginitis caused by Bacillus Coli Communis.

OPHTHALMOLOGICAL SOCIETY

Obliteration of a Branch of the Retinal Artery—Recovery of Sight after Temporary Occlusion of the Central Artery—Traumatic Division of both Optic Nerves

An ordinary meeting of this society was held on June 8th, Mr H. R. SWANZY, the President, being in the chair.

Dr C. E. BERRY and Mr MARCUS GUNY described a case of Obliteration of a Branch of the Retinal Artery following frequent attacks of Temporary Amblyopia. The patient, a man, aged 34 years, had suffered since childhood from temporary attacks of amblyopia lasting a few minutes, and involving especially the right eye, but unattended by headache. About nine months ago, after violent exercise, he had an attack in which the blindness of the right eye was followed by loss of the superior half of the visual field of the right which had persisted and part of the periphery of the lower half of that field. At present on ophthalmoscopic examination there was atrophy of the lower half of the right disc with shrinking of the branches of the lower half of the arteria centralis retinae. He had had occasional attacks affecting the left eye and in one he temporarily lost the lower half of the field of vision of the left eye. There were no other symptoms except that the right knee-jerk was very deficient and very difficult to obtain. The case was considered to be an unusual condition of complete obstruction of a retinal artery which had previously been liable to recurrent temporary constriction.

Mr J. B. STORY reported two cases of Recovery of Sight after Partial Occlusion of the Central Artery. Case 1 was that of a man, aged about 35 years, who was attacked with blindness of the left eye on Dec 28th, 1898, and was first seen on Jan 5th of this year. Externally the eye was normal in appearance, but the pupil did not act to light, vision was reduced to a perception of light. The optic disc was hazy, the arteries were threadlike, and there was a slight cherry colour at the macula, as is seen in typical cases of embolism. Inhalation of nitrite of amyl produced some redness of the fundus and arterial and venous pulsation could be produced by pressure. The patient was apparently healthy and was not rheumatic, his heart was not examined. Iodide of potassium was ordered internally, with daily inhalations of amyl nitrite. After six days he could count fingers at three metres, small doses of corrosive sublimate were ordered. Two weeks after, on Jan 23rd, the pupil was active and vision had become $\frac{1}{2}$, the improvement had begun suddenly four days before. On Feb 7th vision had further improved to $\frac{3}{4}$ and on April 18th it was $\frac{5}{6}$, ophthalmoscopically the eye appeared to be normal.

of the other—that is to say, the heart becomes really hypertrophied. This leads in some way to increased uptake of fluid in the placenta and so to increased exudation by this twin. This increased exudation takes the form of excessive secretion, certainly from the kidneys, probably from the skin, and possibly also from the portion of placenta belonging to the affected foetus, and the accumulation of these discharges leads rapidly to enormous hydramnion of the same foetus. The diagnosis can often be completely made by observing that the signs of a foetus are limited to a small portion of the circumference of a hydramnionic cyst. The appropriate treatment consists in the induction of premature labour by puncture of the membranes. Case 1—Seventh pregnancy, symptoms beginning at the fourth month, labour induced by puncture of the membranes at five and a half months. The larger foetus was contained in 19 pints of amniotic fluid, with large heart and kidneys and thick umbilical cord with dilated vessels. The smaller twin was in a separate amnion with a normal amount of fluid, the umbilical cord was long, thin, and velamentous, common placenta. Case 2—Third pregnancy, symptoms beginning at three and a half months, labour spontaneous at five months, enormous gush of fluid followed by birth of twins contained in their membranes. The larger twin was hydramnionic and the smaller one showed marked atrophy of the wall of the left ventricle, common placenta and chorion.

Dr HERBERT SPENCER congratulated Dr Wilson on the full account which he had given of this interesting condition. With reference to the clinical aspect of the subject he (Dr Spencer) had found that ballottement, impossible to obtain in the dorsal position, could readily be got by placing the patient in the knee elbow position when the foetus sank to the dependent part of the abdomen and could be readily felt there. Adverting to the differential diagnosis between hydramnion and an ovarian tumour he suggested in difficult cases the passing of a bougie. He thought that Dr Wilson took somewhat too limited a view of the causation of the hydramnion in these cases. It was evident that the theory given by him would not explain cases of hydramnion in cases of single foetus and according to that theory hydramnion ought to be excessive in cases of acardiac foetus where the circulation of the two foetuses was carried on by the heart of one, this however, was not the case. He thought that it was a difficult thing to diagnose hypertrophy of the heart in premature foetuses, the size of the viscera varying very much in foetuses of the same size. In one of his own cases of acute hydramnion with homologous twins the foetuses were almost of the same weight (one just over, the other just under, 1 lb 4½ oz) and the hearts appeared to be normal. In this case the cord of the hydramnionic foetus was much twisted near the foetus and oedematous beyond (the placenta and cords weighed 1 lb 7 oz), the oedema thus produced would, he thought, possibly explain the hydramnion in this case, but he did not see how a hypertrophied heart could explain its occurrence. As fluid was found experimentally to exude into the amnion whether injected into the foetal or natural circulation it was possible that hydramnion might arise from abnormalities in either. He agreed with Dr Wilson in regarding the urine as one of the sources of the liquor amnii, if the foetus did not pass urine into the amnion foetal hydro-nephrosis, of which he had seen several examples, would not occur.

Dr A. ROUTH thought that the question of the etiology of hydramnion would not be established without reference to its occurrence in single ova and he did not think that Dr Wilson's theory would explain many of such cases. It did not account for hydramnion occurring in the acardiac twin instead of the hypercardiac, or for the majority of such cases being female and often puny and lacking vitality where the arterial tension must be below normal, or for its frequent occurrence in cases of anencephalus, spina bifida, exomphalos, &c. He thought the diagnosis by means of uterine contractions most helpful and if abdominal ballottement was obtained over all parts of the abdomen by putting the patient in the knee-chest position on either side it proved not only hydramnion but the absence of any complicating ovarian cyst.

Dr GRIFFITH characterised the paper as one of the most valuable contributions to the subject. His own observations had led him to the same conclusions up to a certain point, but he was unable to accept as proved the view that the foetal kidneys were sources of liquor amnii. It had never

been demonstrated that it was possible for a foetus to overcome the tension of the liquor amnii and to pass its secretion, if any, into this sac and there was evidence that it could not do so. The determination of such minute quantities of urea or similar substances was difficult.

Dr WILSON, in reply, emphasised the fact that hydramnion, like dropsy and jaundice, was a symptom which might depend on some one or more of a variety of causes. His contribution was intended to deal with one group only of the cases and no attempt had been made to discuss the causes of hydramnion in general. The number of facts in favour of the renal origin of at least part of the liquor amnii left little room for doubting the truth of the theory. OPHTHALMOLOGICAL SOCIETY

Obliteration of a Branch of the Retinal Artery—Recovery of Sight after Temporary Occlusion of the Central Artery—Traumatic Division of both Optic Nerves

An ordinary meeting of this society was held on June 8th. Mr H. R. SWANZY, the President, being in the chair.

Dr C. E. BEEYOR and Mr MARCUS GUNV described a case of Obliteration of a Branch of the Retinal Artery following frequent attacks of Temporary Amblyopia. The patient, a man, aged 34 years, had suffered since childhood from temporary attacks of amblyopia lasting a few minutes, and involving especially the right eye, but unattended by headache. About nine months ago, after violent exercise, he had an attack in which the blindness of the right eye was followed by loss of the superior half of the visual field of the right which had persisted and part of the periphery of the lower half of that field. At present, on ophthalmoscopic examination there was atrophy of the lower half of the right disc with shrinking of the branches of the lower half of the arteria centralis retinae. He had had occasional attacks affecting the left eye and in one he temporarily lost the lower half of the field of vision of the left eye. There were no other symptoms except that the right knee-jerk was very deficient and very difficult to obtain. The case was considered to be an unusual condition of complete obstruction of a retinal artery which had previously been liable to recurrent temporary constriction.

Mr J. B. STORY reported two cases of Recovery of Sight after Partial Occlusion of the Central Artery. Case 1 was that of a man, aged about 35 years, who was attacked with blindness of the left eye on Dec 26th, 1898, and was first seen on Jan 5th of this year. Externally the eye was normal in appearance, but the pupil did not act to light, vision was reduced to a perception of light. The optic disc was hazy, the arteries were threadlike, and there was a slight cherry colour at the macula, as is seen in typical cases of embolism. Inhalation of nitrite of amyl produced some redness of the fundus and arterial and venous pulsation could be produced by pressure. The patient was apparently healthy and was not rheumatic, his heart was not examined. Iodide of potassium was ordered internally, with daily inhalations of amyl nitrite. After six days he could count fingers at three metres, small doses of corrosive sublimate were ordered. Two weeks after, on Jan 23rd, the pupil was active and vision had become $\frac{1}{2}$, the improvement had begun suddenly four days before. On Feb 7th vision had further improved to $\frac{3}{4}$ and on April 18th it was $\frac{1}{2}$, ophthalmoscopically the eye appeared to be normal.

patient presented. In this case Dr. Thomson thought that the alterations on the bone were more marked at first and then became less so, not on account of any absorption, but because the surrounding parts of the bone underwent a thickening. The mass was seen in the middle of the crania of syphilitic children where the lancet-shaped bosses gradually disappeared by reason of the filling up of the valleys between, the whole bone becoming thickened and cancellated. Mr. Caird thought that the section of bone exhibited presented nothing of a special type, but said that if the patient had lived if might have become denser than any other bone, much as was met with in the case of septic bone disease. Mr. ALFRED THOMSON said that one saw similar conditions in bones and specially in the tibia in other bone diseases. He objected to the term "syphilitic osteitis"—Dr. JAMES replied.

KIDNEY-DISEASE ALLEGEDLY SOCIETY—A meeting of this society was held on May 26th. Mr. E. H. Addison, President, being in the chair.—Mr. J. Lionel Street showed—A young woman, aged 21 years, upon whom he had operated 10 weeks previously for Tuberculous Peritonitis. She walked about out-of-doors and expressed herself quite well, the abdomen appeared to be normal, and she had gained 12 pounds in weight. She had been taking creosote in doses increasing by one minim each day and was now taking 60 minims three times a day. On several occasions disappeared in a day or two without disclosing anything to the medicine. A portion of the omentum was sent to the Clinical Research Association and they reported as follows: "This tissue is infiltrated with an abundance of grey and caseous material. The giant cells of grey and caseous infiltrates. The giant cells systems are well developed." 2 The pyloric end of the stomach with part of the Duodenum removed from a man, aged 67 years. He had suffered from gastric symptoms for some months and had been an in-patient the early part of the year, during which time he was thoroughly examined under an anæsthetic with a negative result. Although somewhat relieved by treatment his symptoms soon returned when he went out. He chiefly complained of severe pain in the stomach which was increased during the night, he stated that he had never had hæmatemesis, but that he vomited at times, though this never occurred while he was in the hospital, and he had lost flesh. The abdomen was opened in the middle line above the umbilicus, there was a considerable thickness of fat and the omentum was bulky. Tucked up beneath the liver was a large mass of growth involving the pyloric end of the stomach which after separating the whole circumference of the organ, but the larger portion was on the lesser curvature. The whole of the diseased part was excised which involved the removal of one-third of the stomach and one and a half inches of the duodenum. The stomach was closed with sutures except the lower angle which was joined to the duodenum with a Murphy's button. He bore the operation well and passed a comfortable night, the next day he was quite himself and had rallied from the shock, but at 3 p.m. the following morning he had a sudden attack of cardiac failure and died in spite of all efforts to revive him. Nothing was found post mortem to account for death. The stomach was resected and held water without leak. The chief points of interest were (1) the slight symptoms, (2) the negative results of abdominal examination due to the thickness of the walls and the position of the growth, and (3) the sudden death. Although attributed to cardiac failure there was no evidence of its cause and everything had been done to guard against it.—Mr. F. OUPHANT read notes of a case of Pyramis treated with anti-streptococcal serum. The man, aged 23 years, was admitted with stiffness and swelling in the left side of the neck which commenced two days previously. At first it was regarded as a case of inflammation of the lymphatics, but pyramis symptoms soon developed. On April 17th and there following days he had an injection of serum (10 cubic centimetres). There was not much effect upon his general condition, though the local symptoms were decidedly improved, and he died on the 24th. Mr. OUPHANT considered that he was benefited by the treatment and it had been given earlier a favourable result might have been obtained.—Mr. W. JAMES read a paper on Adenoid Vegetations in the

Reviews and Notices of Books.

A CLASS BOOK OF ELEMENTARY PRACTICAL PHYSIOLOGY By DR. BURGH BIRCH, M.D., C.M., F.R.S. Edin., Professor of Physiology in the Yorkshire College of the Victoria University, London. J. A. Churchill 1899. Pp. 273. Price 6s. 6d.

THIS work is an expansion of the notes which the author places before the students attending his course of practical physiology in the Yorkshire College and is divided into three sections. The first deals with histology, the second with chemistry in so far as it is required in medicine, and the third is devoted to a description of the more simple and fundamental physiological experiments. The size of the volume precludes the giving of details of the structure of the several organs, but the names applied to the parts are mentioned to indicate to the student the points for which he must look, as, for example, in the case of the bones, the lamellæ and their disposition, the ground substance lacunæ Haversian spaces and the appearances presented in ossifying cartilage. In the preliminary exercises with the microscope the method of employing a warm stage is well described, but the mode of measurement of an object is overlooked, the method of measuring a simple appliance for fixing animal tissues by injection and a considerable number of formulae for hardening and staining tissues is given, such for example, as Weigert's album stain, Golgi's chromate of silver process and Ramon y Cajal's double impregnation method. The various tests for glycogen, saccharose, and amyloses, and for fats and proteins are fully and satisfactorily, though briefly, described. The chapter on Normal and Abnormal Urine is very good. The principal apparatus required in physiological experiments are described and illustrated by very good woodcuts and the fundamental experiments of physiology are given. There are several errors which require correction, Hensen being spelled Hensen, Engelmann, Engelmann, Hensen. There are several errors which require correction, Hensen being spelled Hensen, Engelmann, Engelmann, Hensen.

WIGAN MEDICAL SOCIETY—A meeting of this society was held on June 8th, Mr. C. R. Graham occupying the chair in the unavoidable absence of Mr. L. Cooke (the President).—A vote of condolence was unanimously passed to Mr. W. Mitchell Hooper and family on the death of his father, Mr. William Hooper, J.P., a former President of the society.—It was proposed by Dr. Benson and seconded by Mr. ALMON, and carried with acclamation, that the society tender its hearty congratulations to Sir William Mitchell Banks on the mark of distinction accorded him recently by Her Gracious Majesty the Queen.—The Secretary read the following resolution on vaccination which had been received from the honorary secretary of the Medical Institution, Liverpool.—

That the members of the Liverpool Medical Institution are of opinion that the Vaccination Act of 1853 was enacted in direct opposition to the findings of the Royal Commission and that the operation of the Act will be prejudicial to the public safety and that the amendment is urgently required.

It was proposed by Dr. Benson and seconded by the Honorary Secretary that the society support the resolution of the Liverpool Medical Institution. It was then proposed that the letter and resolution lie on the table, an interesting discussion followed, a further amendment being proposed and carried unanimously to the following effect:—

That this meeting is of opinion that Parliament should make efficient vaccination compulsory, that the sanitary authority should have the carrying out of the Vaccination Act that the cost of vaccination should be a matter of local charge and that private practitioners and public vaccinators should be paid the same fees from the Exchequer fund.

The following members took part in the discussion: Dr. Benson, Dr. Hees, Mr. Bradbury, Mr. Parker, Mr. Brady, Mr. Wilding, Mr. Graham, Mr. Almon, and the Honorary Secretary. The President's address was postponed till the next meeting.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

Exhibition of Cases and Specimens—Congenital Syphilitic Osteitis

THE ninth ordinary meeting of this society was held, on June 7th, Dr CRAIG being in the chair.

Mr SHAW M'LAREN showed a boy on whom he had performed Disarticulation at the Hip. The lad, was a pit-head worker who was caught by the hitches and driven through a narrow opening, subsequently falling a considerable height. The accident produced what was really an amputation through the middle of the right thigh. The operation was performed 12 hours after the accident. Hæmorrhage was completely and most satisfactorily prevented by digital pressure on the abdominal aorta by an assistant. The lad was young, however, and as the abdominal walls were thin compression was easily effected. At the end of the operation, though very little blood had been lost, the patient was pulseless. A pint of saline fluid was then injected into his median basilic vein, and together with enemata of hot coffee (no alcohol was employed) his condition soon improved. Parts of the flaps had been badly crushed by the accident and later these sloughed and prevented union by first intention.

Mr OATHCART showed a patient after operation for a Perforated Vermiform Appendix with General Peritonitis. Recovery after such a state of affairs was infrequent. The woman was admitted to the Royal Infirmary five days after the first onset of the symptoms, but as these symptoms were very slight during the first two days it may be said that she was admitted on the third day really. Her condition then was very critical, there seemed to be general peritonitis with a localising towards the right side. The incision was therefore made to the right of the median line and the appendix was found to have sloughed as far as its junction with the caecum. Very fetid pus was present as well as a small concretion in the pelvis. As each loop of intestines was investigated a pocketful of fetid fluid escaped. As had been recommended, the intestines were then pulled out loop by loop from the wound and thoroughly washed, as was also the abdominal cavity. The caecum was so distended that it required to be punctured. As the wound which remained after the sloughing of the appendix was soft and friable it was not sutured but the neighbourhood was packed with gauze. No peritonitis ensued subsequently, but pieces of the right rectus muscle sloughed away during the healing process. This showed that the peritoneum was much less susceptible to infection than were the other tissues, as the rectus was only once touched by the septic fluid during its escape. At present a small valvular sinus remained in the wound and apparently communicated with the bowel, as when coloured fluid was injected it appeared in the motions, though none of the faeces ever escaped.

Mr CAIRD exhibited a man who evidently had suffered from Congenital Syphilis. At present he possessed a hard sore on the penis, he had a secondary syphilitic rash and was losing his hair. The case was apparently one of congenital together with secondary syphilis.

Dr SHENKIN exhibited the following specimens—1 Malignant Pustule. The specimen was characteristic—sloughy centre and oedematous surroundings, and ifogy of section through it the anthrax bacilli could be seen lying to the tissue spaces. 2 Sarcoma in the Tip of the Pa that Dr sphenoidal Lobe. 3 Calcareous Deposit in an cases. It did and extending into the Tunicæ. The size in the cardiac twin old man, aged 75 years, and resulted for the majority of such culous deposit. 4 Extensive & puny and lacking vitality. Men was from a woman whose be below normal, or for its freck became uranic. She of anencephalus, spina bifida, axomphalic face or limbsight the diagnosis by means of uterine conxvoman died & helpful and if abdominal ballotte ment was obtanf hender all parts of the abdomen by putting the patient in the knee chest position on either side it proved not only hydramnion but the absence of any complicating ovarian cyst.

Dr GRIFFITH characterised the paper as one of the most valuable contributions to the subject. His own observations had led him to the same conclusions up to a certain point, but he was unable to accept as proved the view that the foetal kidneys were sources of liquor amnii. It had never

Dr ALEXANDER JAMES communicated a paper on a Case of Congenital Syphilitic Osteitis. The patient was a lad, aged 18 years. His family history was distinctly syphilitic. His mother had a son by her first husband and he seemed to have suffered from a similar disease to the present patient's, and died when 13 years of age. Of the same family as the patient a boy died when seven weeks old from some unknown cause, next a boy was born with some swelling on his back and he only lived six days, next came a miscarriage at the third month, followed by a son who died 11 weeks later. Two abortions followed and then four children who were alive and healthy. Dr. James had noted that in such families great fecundity was the rule. As an infant the patient had neither snuffles nor rash. When two years old, however, he had keratitis. The present illness began when he was nine years of age subsequently to an attack of measles and whooping-cough. He then began to suffer from pains in the arms and legs and a swelling (node) at the middle of the right tibia. The latter enlarged and was painful at intervals. In 1892 Dr John Thomson saw the patient and found that the lower ends of both humeri were enlarged and that there were localised swellings (nodes) on both tibiae and on the right scapula. Under iodide of potassium the patient improved. In 1897, when he was first admitted to the ward, he had great pain in the right leg and there was a diffuse thickening of the right tibia. The left tibia was also enlarged. At this time he complained of no arm trouble and again improved under iodides. In May, 1898, he first noticed that the index and middle finger of the right hand had become weak and this weakness soon affected all the fingers of that hand. For five weeks before admission he had suffered from headaches which were always worse at night. Twitchings of the right hand and arm followed. On admission he was found to be a badly grown lad of five feet four inches, his muscular development was poor and he was dull and apathetic. There was no rise of temperature. The right tibia was thickened throughout its length and slightly curved inwards. It was also about three quarters of an inch longer than the left, as may also have been the case with the right femur as contrasted with the left. There were no special changes in the sensory functions but loss of motion was present in the right forearm and hand. His vision was blurred and especially in the left eye, optic neuritis was present. The plantar and epigastric reflexes were more marked on the left side but the deep reflexes were all absent. The lymphatic glands in either groin were enlarged, as were others also, and the spleen measured seven and a half inches in length by five inches in breadth. The arterial walls were thickened and this thickening was especially marked in the veins of the leg, the saphenous vein standing out like a tendon. The diagnosis was that of hereditary syphilis. Nodes had been present previously but these had disappeared, leaving a diffuse osteitis (local gantism). There was also a tumour in the left Rolandic area affecting the right hand and arm centre. Under large doses of iodide he improved somewhat but went home and died on Jan 15th, 1899. The post-mortem examination was imperfect but a tumour of the size of a golf ball was found as diagnosed and a disc like portion of the right tibia was removed. The latter showed that the tibia consisted of a thin rim of dense bone at the periphery with the interior entirely filled up with cancellated tissue, leaving no medullary cavity. Under a higher magnification much fat and marrow cells were seen to be present in the bone. The disease was evidently one of distinct specific disease. The case had been formed and had then disappeared. The nodes of which were present were rather parasymphilitic than Jan 5th of Still later, however, the hereditary disease appearance, but the shape of the cerebral gumma. Such reduced to a pld such a patient take syphilis afresh? the arteries were in syphilis any connexion colour at the mac of osteitis? might be asked. This Inhalation of nit an increase in quantity at the of the fundus ant had caused a reversion to an earlier be produced by pn the bone. There had also been an healthy and was of the bone. It was said that general examined Iodide from such osteitis and it was true that with daily inhalation exhibited as such were syphilitic. On he could count finger, they found dwarfism as a result of rovie sublimate weilon of the bone might have resulted 23rd, the pupil was which produced its increase in thick- improvement had been thought that what Dr James 7th vision had fue merely limited patches of osteitis and was &, ophthalmic also objected to the term "parasymphilitic" but there had been no gap in the symptoms which this

The Practice of Obstetrics By American Authors Edited by CHARLES JEWETT, M.D. Illustrated with 441 Engravings, 34 of which are in colours, and 22 Coloured Plates 8vo London Henry Kimpton 1899 Pp 770 Price 25s net

THIS volume is described as the work of obstetric teachers and of other experts in the cognate lines on which they have written. It is, as such books usually are, of very unequal merit, and while some of the contributions are of great value others by no means reach the same standard of excellence. The book is divided into eight parts, dealing respectively with Anatomy, the Physiology and Pathology of Pregnancy, Labour and the Puerperium and Obstetric Surgery. The chapter upon Anatomy is good and clear and contains a full account of the anatomy of the contents of the pelvis.

In Part II we are inclined to think that the section devoted to the Development of the Ovum is too full and detailed for a work of this kind. It is pretty certain to be skipped by the average student, while the practitioner desiring a complete account of the subject would do better to refer to a work dealing especially with embryology.

The rest of the chapters upon the Physiology of Pregnancy contain all the essential details. The anatomical description of the bony pelvis is good and we are glad to see that the author gives the measurements both in inches and in centimetres. The mechanism of labour is but poorly described and no account appears to have been taken of the valuable results obtained by the study of frozen sections in this connexion. The description of the mechanism of the third stage of labour is no better and a student reading the short paragraph devoted to this important subject would quite fail to get any clear idea of the various views held at the present day as to how the separation of the placenta really occurs. In the management of normal labour the use of antiseptics is fully discussed and due stress is laid both in this chapter and in that upon Puerperal Infection upon the great importance of abdominal palpation and the avoidance of unnecessary vaginal examinations. Walcher's position is illustrated by a full page photograph of a patient in that posture and is recommended in several places in the book, but no mention is made of the fact that the increase in the conjugate diameter is not believed in by everyone and is, indeed, denied by some obstetricians of note. The chapter upon the Care and Management of the New born Child contains a very good account of infant feeding upon a scientific basis. The sections upon the Anomalies and Diseases of the Fœtus, consisting as they do of little more than a catalogue of names, are of little value, although illustrated by some good photographs from Hirst and Piersol's Atlas.

We entirely agree with the recommendation that a sharp and not a blunt curette should be used in the treatment of cases of incomplete abortion. With a sharp instrument the amount of force employed can be carefully graduated and the decidua can be more certainly and just as safely removed as with the blunt curette. The chapter upon Puerperal Infection is from the pen of Dr. Whitridge Williams. As might be anticipated the bacteriological and pathological aspects of the subject are very fully considered and a very interesting review is given of the work done upon the question of the presence or absence of pathogenic organisms in the vagina and the possibility of auto-infection. Dr. Williams draws attention to the important difference between cases of septic and putrid endometritis and the uselessness of local treatment in cases of acute septicæmia with few or no local changes. He does

not regard with favour the operation of hysterectomy in the early stages of puerperal infection and, as he points out, if the operation be done sufficiently early a large number of uteri will be removed unnecessarily, while if it be put off until other organs are involved it will in the majority of cases prove useless. This is one of the best accounts of puerperal infection which has so far been written and will well repay perusal. A slight typographical error is to be noted on pp 571 and 572, the descriptions of Figs 353 and 354 having been transposed. The best part of the chapter upon Obstetric Surgery is the account of Version and of Symphysiotomy. The illustrations are mainly derived from other sources, so that many of them are familiar, but a good choice has been made. The book is one which will be found very useful for purposes of reference and does credit to the editor and the gentlemen who have contributed to its production.

Life of Man on the High Alps By ANGELO MOSSO Translated from the Second Edition of the Italian by E. LOUGH KIESOW 1898 London T. Fisher Unwin Pp 342 Price 21s

THE barometric conditions under which the vast majority of the human race live and work are on the whole so very uniform that much interest naturally attaches to an investigation into the differences resulting from any considerable variation in the atmospheric pressure. Professor Angelo Mosso has devoted much time and care to the question as to the effect on the human body of greatly reduced pressures and his results are presented in this volume. Early in 1894 the Regina Margherita hut was completed on the summit of Monte Rosa, at a height of 4560 metres (15,000 feet), and the author decided to undertake a series of researches into the effects on human beings produced by this altitude. By the permission of the Italian Minister for War he was permitted to take with him 10 men of the Alpine regiment under the command of an army surgeon. A number of soldiers at once volunteered and some preliminary investigations were undertaken with the object of ascertaining the physiological conditions of the men under ordinary circumstances. It is so very easy to confuse the effects of fatigue with those of lessened barometric pressure that Professor Mosso took special care to avoid this error. In addition to the author and the soldiers the party contained the author's brother, Ugolino Mosso, Professor of Pharmacology at the University of Genoa, Dr. Vittorio Abelli, an army surgeon, and a medical student, Signor Beno Bizzozero, to whom are owing most of the numerous photographs which adorn the book. Unfortunately he died a year after the expedition returned.

It has always hitherto been stated that at great altitudes respiration is more rapid and more profound, but this error is due to the long duration of the disturbing influence of the ascent, for in persons in complete repose dwelling at great heights the breathing has been found by the author not to increase either in frequency or in depth, but even to diminish, and a careful measurement of the quantity of air expired showed that less air was inhaled at these great altitudes. The effect on the heart and circulation is but slight unless the change from a low to a great altitude has been made rapidly, in that case there may be a considerable increase in the number of pulsations of the heart and the blood pressure is diminished. In order to register the mechanical work of the muscles the author devised a machine which he called an "ergograph," it registered the contractions of the middle finger which were executed rhythmically following the movements of a pendulum. It was found that on Monte Rosa the force of the muscles was slightly diminished, but that the total amount of the work accomplished was only slightly less than in the

plasm. In addition to these original articles there are
included in the part the Proceedings of the Physiological
Society

NEW INVENTIONS.

AN IMPROVED NEEDLE-HOLDER.

HITHERTO needle-holders of any use have been too
expensive and not always capable of being readily rendered
aseptic. The illustration below shows an improved form
of aseptic needle-holder which has been introduced by
Messrs Arnold and Sons of West Smithfield and which
possesses distinct advantages over those at present in
use. (1) It is made in two pieces only, (2) it is
very simple in construction and there are no complicated

Holder holding needle. Holder taken to pieces for cleaning.

The jaws open by compressing the spring handle. This being the case
I think it possible that their grip might loosen if the
operator were trying to pass the needle through very tough
tissue for he would instinctively tighten his grip on the
handle. To obviate this we would suggest the addition of a
stop-plate or catch, easily removable, which would prevent
when necessary the sliding of the one blade on the other.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

On the recommendation of the Council was held on June 8th,
the President, Sir William MacCormac Bart., K.C.V.O.,
being in the chair.

On the recommendation of the Council of Examiners the
Council amended Clause 4 Section 1 of the regulations for
the Diploma of Fellow. The effect of the alteration is that
the first winter session spent at a recognised science insti-
tution may be counted in lieu of one of the three winter
sessions at a recognised medical school required for the first
examination for the Fellowship of the College.

A draft memorial was received from some members of the
College recently endorsing the proposal.

be obtained to confer the Fellowship of the College upon
persons who are not Members and asking the Council to
include in the proposed supplementary charter some scheme
for the representation of Members of the College upon the
Council. The Secretary was directed to write in reply that
it had been determined to include only one matter in the
application for a new charter as it was inappropriate to intro-
duce anything else.

The draft petition and draft charter relating to the insti-
tution of an Honorary Fellowship were presented to the Council
and were approved with the exception that Members of the
College are to be eligible for the Honorary Fellowship and
that the number of Honorary Fellows is never to exceed 50.
It was resolved that a meeting of Fellows and Members
should be summoned for Wednesday, July 5th, 1899, at 3 p.m.
to consider the draft petition and charter, and that copies of
these documents should be supplied to Fellows and Members
applying for them.

The following examiners were appointed—
Examiners in Elementary Biology under the Examining Board in
England—Reginald F. B. Bate, F.R.S.E., Guyer Parsons Thomas
William Shore, and Thomas George Stevens.
Examiners in Anatomy and Physiology under the Examining Board
in England—Alexander Standen Boyd William Bruce Clarke, Arthur
Robinson, and Arthur Thompson. Physiology John Rose Bradfield.
George Alfred Buckmaster and Leonard Brinkne Hill.
Members of the Board of Examiners in Anatomy and Physiology for
the Fellowship of the College—Anatomy James Ernest Lane, Berkeley
G. A. Moynihan F.R.C.S., Guyer Parsons and Alfred Harry Kemp.
Physiology Thomas Edgar Brodie Darcy Power Ernest Henry
Selling and William Henry Thompson.
Examiners in Midwifery under the Examining Board in England—
William Bradford Davis, Walter S. A. Gushie Arthur H. V. Leaver, and—
Honorary British Specialist
Examiners for the Diploma in Public Health—Part I. Arthur
Pearson Part II. Sydney Arthur MacCormac Copeman.

Mr Henry Morris was elected a member of the Court of
Examiners.

The Secretary laid before the Council a letter from the
Royal Institute of Public Health forwarding a copy of a letter
to the Council relative to the appointment of a medical officer
to the Education Department and asking the College to make
a similar representation

On the occasion of the presentation at the Baron Hall, Aberaman,
on May 31st, of certificates to the ambulance students Mr.
Thomas Finney, L.R.C.P., L.R.C.S. Edin., L.F.S. Glasg.,
the instructor, was the recipient from the class of a valuable
waiding stick as a token of appreciation of his services.—
On May 31st Mr C. T. Dingle, M.D., B.S. Durm., who
12 months since left Newcastle to take the position
of medical officer of health of the Middlesbrough Cor-
poration, was the recipient of a testimonial on the occasion
of his approaching marriage from the public officials
of the former town and the chairman of the Sanitary Com-
mittee as a mark of esteem and goodwill. The testimonial
consisted of a silver tea service.—Mr Charles White,
M.R.C.S. Eng., the senior medical practitioner of War-
rington, attended on June 5th his seventieth year and his
professional brethren marked the event by making him
a presentation of plate. Mr J. H. Gortall the medical
officer of health, made the presentation at Mr White's
residence, Dr G. W. Joseph and Mr J. S. Sphenant and
Mr E. A. Fox being present and joining in the congrat-
latory address.—Mr White on the auspicious anniversary
Mr White is not only well known but highly respected in
the borough.—Dr J. Scott Hiddell, teacher of the Aberdeen
city police ambulance class, has received from the officers
and men a gift in the shape of a silver cigarette-case
inscribed as follows: "Presented to J. Scott Hiddell,
Esq., M.D., by Aberdeen Police Ambulance Class 1899."

The presentation was made by Constable Wynnes
on the occasion of the distribution of certificates.

POISONING BY SALTS—At St Marychurch,
Torquay, on June 5th, an inquest was held upon the body of
a man, aged 71 years. The evidence showed that a few days
previously the deceased purchased some sausages at Torquay
and after having eaten them he was taken ill and eventually
died. A post-mortem examination showed that death
resulted from eating unwholesome food which caused
poisoning. A verdict of "Death from mis-
adventure" was returned and the jury awarded £100 to
be paid to the executor of the deceased at the time of
sale during hot weather.

going on for some time between these two psychologists¹ is accounted for and the differences are reconciled.

The Mechanism of Reasoning is treated (Chapter iv) in an admirable way, and the discussion is illustrated by concrete instances and by experiments designed to explain the operations involved. Dr. Here is strongly influenced by the psychology of the English and American schools, and frequent are the references to Herbert Spencer and Galton, as well as to Bain and William James. It is difficult to give within the limits of this review an outline of this chapter. It is one which will repay careful study.

We must add that in the general body of the work many examples chosen (and in the majority of instances very happily) from the domain of mental pathology and of hypnotism are used to explain and illustrate the author's meaning. The work is throughout distinguished by that lucidity and proportion characteristic of the best work of the French school, and this little book can be heartily recommended to readers interested in the study of psychology who wish for something more solid than academic speculations and theories.

The Foundations of Zoology. By W. K. BROOKS, Ph.D., LL.D., Professor of Zoology in the Johns Hopkins University. London: Macmillan and Co. Pp. 339. Price 10s. 6d.

THIS volume consists of reprints of a course of lectures delivered at Columbia University on the Principles of Science as Illustrated by Zoology. Some of these lectures have already appeared in various ways, but there can be little doubt that the author has been well advised in presenting them to the scientific world in a complete form. Perhaps we cannot give an idea of the scope of the work in a small space better than by quoting the titles of the 13 lectures of which it is made up. They are: 1. Introductory. 2. Huxley and the Problem of the Naturalist. 3. Nature and Nurture. 4. Lamarck. 5. Migration and its Bearing on Lamarckism. 6 (Part 1). Zoology and the Philosophy of Evolution. 6 (Part 2). A Note on the Views of Galton and Weissman on Inheritance. 7. Galton and the Statistical Study of Inheritance. 8. Darwin and the Origin of Species. 9. Natural Selection and the Antiquity of Life. 10. Natural Selection and Natural Theology. 11. Paley, and the Argument from Contrivance. 12. The Mechanism of Nature. 13. Louis Agassiz and George Berkeley.

It will be seen from the foregoing list that many of the most interesting questions of modern zoology are discussed in this volume and the work gives a fair summary of the views of eminent men of science who have turned the thoughts of zoologists in different directions. At the same time it expresses the author's views, sometimes clearly, sometimes obscurely, to those who have not hitherto devoted much time to the study of the factors which govern animal life. From our point of view the thing to be considered is how the work is likely to interest and to be of value to men whose powers of observation have been sharpened by continual use but who have not had time to devote to deep abstract thought on metaphysical subjects.

From such a standpoint we should say that many of the author's ideas are not to be grasped without considerable mental strain and even then it is difficult to be sure that one rightly apprehends them. Perhaps his meaning is not always expressed in the happiest and most lucid form, perhaps more illustrative examples of his contentions would have been advantageous, although it must be confessed that his pages are by no means lacking in these. Much space is rightly given to the subject of Natural Selection and if we understand him aright the author leans to the conviction that while this is the chief factor in the evolution of species

there may still be a residuum to be accounted for by the inheritance of acquired characters.

We feel sure that while there may be much in this book with which all will not agree, even much which all will not understand, the mental exercise of honestly attempting to master all the arguments in it cannot fail to do good.

Aseptic Duties of a Surgical Nurse or Dresser. By JOHN O'CONOR, M.A., M.D. Dub., Senior Medical Officer, British Hospital, Buenos Ayres. Buenos Ayres: John Grant and Sons.

THIS little book, as the author tells us in his preface was originally written for the use of the nurses at the British Hospital at Buenos Ayres but is now published in the hope that it may have a wider field of usefulness. It will undoubtedly, we think, be of service to nurses in out-of-the-way places, to say nothing of dressers even in large hospitals. The directions are very clearly given and the author, although not claiming that his methods are the only ones, yet gives no choice of details, for, as he very truly says, "If one has two or more methods of asepsis sepsis generally results." The book is, we believe, about to be published in England by Mr. H. K. Lewis.

JOURNALS

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. WELDON, F.R.S. New Series, No. 166. Vol. XLII. Part 2. London: J. & A. Churchill. 1899. Price 10s. —A notice is given in this part that the issue of the *Quarterly Journal* will not be limited as heretofore to four parts or numbers in the year, but that as there is an accumulation of material in the hands of the editors additional parts will be published at such intervals as may appear advisable. The present part contains a Memoir on the Development of the Parietal Eye and Adjacent Organs in *Sphenodon* (Hatteria), by Professor Arthur Dendy, F.L.S., of the University of New Zealand. Professor Dendy has been fortunate in securing a considerable number of the eggs of the *Sphenodon* and has extracted from them a very good series of embryos. The article is illustrated with 28 figures, showing the median eye of this lizard in all stages of development. The second article is a continuation of the memoir by Mr. J. E. S. Moore on the Mollusks of the Great African Lakes, in which descriptions and drawings are given illustrating the form and structure of the *Tanganyika rufofilosa*, *Melania episcopalis*, *Littorina littorea*, *Spekia zonatus*, *Nassopis*, *Bythocaras*, and others. The next article is by Lily H. Huie who dates from the Physiological Laboratory, Oxford, and writes on the Further Study of Cytological Changes produced in *Drosophila*, giving some good coloured illustrations of the changes in the cells of the *Drosophila* at different periods after feeding. The last article is by Dr. Arthur Willey, M.A., and is entitled Remarks on Some Recent Work on the Protochorda, with a Condensed Account of Some Fresh Observations on the Enteropneusta.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, M.D. Lond., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. xxiv. No. 2. May 11th, 1899. London: C. J. Clay and Sons. Price 7s. —The articles contained in this part are: 1. W. M. Bayliss and E. H. Starling. The Movements and Innervation of the Small Intestine, with 30 figures in the text. 2. A. E. Boycott. Note on the Muscular Response to two Stimuli of the Sciatic Nerve in the Frog, with six figures in the text. 3. A. Haig, M.D. Oxon. Some Remarks on the Excretion of Uric Acid and its Relation to

¹ *Revue Philosophique* 1883 and 1884 *passim*.

AN IMPROVED NEEDLE-HOLDER

HITHERTO needle-holders of any use have been too
expensive and not always capable of being readily rendered
aseptic. The illustration below shows an improved form
of aseptic needle holder which has been introduced by
Messrs Arnold and Sons of West Smithfield and which
possesses distinct advantages over those at present in
use (1) It is made in two pieces only, (2) it is
very simple in construction and there are no complicated

parts to get out of order, and (3) it is very cheap. The jaws
open by compressing the spring handle. This being the case
we think it possible that their grip might loosen if the
operator were trying to pass the needle through very tough
tissue for he would instinctively tighten his grip on the
handle. To obviate this we would suggest the addition of a
stop-plate or catch, easily removable, which would prevent
when necessary the sliding of the one blade on the other.
The instrument may be easily boiled when taken to pieces.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council was held on June 8th,
the President, Sir William Mac Cormac, Bart, K C V O,
being in the chair.

On the recommendation of the Court of Examiners the
Council amended Clause 4 Section 1, of the regulations for
the Diploma of Fellow. The effect of the alteration is that
the first winter session it spent at a recognised science insti-
tution may be counted in lieu of one of the three winter
examinations at a recognised medical school required for the first
examination for the Fellow ship of the College.
A draft memorial was received from some Members of the
College cordially endorsing the proposal that power should

be obtained to confer the Fellowship of the College upon
persons who are not Members and asking the Council to
include in the proposed supplementary charter some scheme
for the representation of Members of the College upon the
Council. The secretary was directed to write in reply that
it had been determined to include only one matter in the
application for a new charter as it was inappropriate to intro-
duce anything else.

The draft petition and draft charter relating to the insti-
tution of an Honorary Fellowship were presented to the Council
and were approved with the exception that Members of the
College are to be eligible for the Honorary Fellowship and
that the number of Honorary Fellows is never to exceed 50.
It was resolved that a meeting of Fellows and Members
should be summoned for Wednesday, July 5th, 1899 at 3 p. m.
to consider the draft petition and charter, and that copies of
these documents should be supplied to Fellows and Members
applying for them.

The following examiners were appointed—

*Examiners in Elementary Biology under the Examining Board in
England.*—Section 1: B Beale, Frederick Gymer Parsons, Thomas
William Shore, and Thomas George Stevens.
*Examiners in Anatomy and Physiology under the Examining Board
in England.*—Anatomy: Stanley Boyd, William Bruce Clarke, Arthur
Robinson, and Arthur Thompson. Physiology: John Rose Braden, Hill,
George Alfred Buckmaster, and Leonard Brinkley Hill.
*Members of the Board of Examiners in Anatomy and Physiology for
the Fellowship of the College.*—Anatomy: James Ernest Lane, Berkeley,
G. A. Molyneux, Frederick Gymer Parsons, and Alfred Harry Young.
Physiology: Thomas Grigor Brodie, David Fowler, Ernest Henry
Blaith, and William Henry Thompson.
Examiners in Midwifery under the Examining Board in England.—
William Radford Dakin, Walter S. A. Grimthorpe, Arthur H. N. Leaver, and
Herbert Ritchie Spencer.
Examiners for the Diploma in Public Health.—Part 1: Arthur
Pearson Lund. Part 2: Sydney Arthur Monkton Copeman.

Mr Henry Morris was elected a member of the Court of
Examiners.

The Secretary laid before the Council a letter from the
Royal Institute of Public Health forwarding a copy of a letter
to the First Lord of the Treasury and the Lord President of
the Council relative to the appointment of a medical officer
to the Education Department and asking the College to make
a similar representation.

PRESENTATIONS TO MEDICAL MEN—On the
occasion of the presentation at the Baron Hall, Aberaman,
on May 31st, of certificates to the ambulance students Mr.
Thomas Finney, L R O P, L R O S Edin, L R P S Glasg,
the instructor, was the recipient from the class of a valuable
walking stick as a token of appreciation of his services.
12 months since left Newcastle to take the position
of medical officer of health of the Middlesbrough Cor-
poration, was the recipient of a testimonial on the occasion
of his approaching marriage from the public officials
of the former town and the chairman of the Sanitary Com-
mittee as a mark of esteem and goodwill. The testimonial
consisted of a silver tea service—Mr Charles White,
Mr R O S Eng, the senior medical practitioner of War-
thington, attended on June 5th his seventieth year and his
professional brethren marked the event by making him
a presentation of plate. Mr J H Gornall, the medical
officer of health, made the presentation at Mr White's
residence, Dr G W Joseph and Mr J S Sherratt and
Mr E A Fox being present and joining in the congrat-
ulations offered to Mr White on the auspicious anniversary.
Mr White is not only well known but highly respected in
the borough—Dr J Scott Riddell, teacher of the Aberdeen
city police ambulance class, has received from the officers
inscribed as follows: "Presented to J Scott Riddell,
Esq, M D, by Aberdeen Police Ambulance Class 1899"
on the occasion of the distribution of certificates
POISONING BY SAUSAGES—At St Marychurch
Torquay, on June 5th, an inquest was held upon the body of
a man, aged 71 years. The evidence showed that a few days
previously the deceased purchased some sausages at Torquay
and after having eaten them he was taken ill and died.
A post-mortem examination showed that a condition
resulted from eating unwholesome food which had
poisoned poisoning a verdict of "Death from food-
poisoning" was returned and the jury warned to be careful
as to the condition of the sausages at home who was
able during hot weather.

going on for some time between these two psychologists' is accounted for and the differences are reconciled.

The Mechanism of Reasoning is treated (Chapter iv) in an admirable way, and the discussion is illustrated by concrete instances and by experiments designed to explain the operations involved. Dr Fere is strongly influenced by the psychology of the English and American schools, and frequent are the references to Herbert Spencer and Galton, as well as to Bain and William James. It is difficult to give within the limits of this review an outline of this chapter. It is one which will repay careful study.

We must add that in the general body of the work many examples chosen (and in the majority of instances very happily) from the domain of mental pathology and of hypnotism are used to explain and illustrate the author's meaning. The work is throughout distinguished by that lucidity and proportion characteristic of the best work of the French school, and this little book can be heartily recommended to readers interested in the study of psychology who wish for something more solid than academic speculations and theories.

The Foundations of Zoology By W. K. BROOKS, Ph.D., LL.D., Professor of Zoology in the Johns Hopkins University, London. Macmillan and Co. Pp. 339. Price 10s. 6d.

THIS volume consists of reprints of a course of lectures delivered at Columbia University on the Principles of Science as Illustrated by Zoology. Some of these lectures have already appeared in various ways, but there can be little doubt that the author has been well advised in presenting them to the scientific world in a complete form. Perhaps we cannot give an idea of the scope of the work in a small space better than by quoting the titles of the 13 lectures of which it is made up. They are: 1. Introductory. 2. Huxley and the Problem of the Naturalist. 3. Nature and Nurture. 4. Lamarck. 5. Migration and its Bearing on Lamarckism. 6 (Part 1). Zoology and the Philosophy of Evolution. 6 (Part 2). A Note on the Views of Galton and Weismann on Inheritance. 7. Galton and the Statistical Study of Inheritance. 8. Darwin and the Origin of Species. 9. Natural Selection and the Antiquity of Life. 10. Natural Selection and Natural Theology. 11. Paley, and the Argument from Contrivance. 12. The Mechanism of Nature. 13. Louis Agassiz and George Berkeley.

It will be seen from the foregoing list that many of the most interesting questions of modern zoology are discussed in this volume and the work gives a fair summary of the views of eminent men of science who have turned the thoughts of zoologists in different directions. At the same time it expresses the author's views, sometimes clearly, sometimes obscurely, to those who have not hitherto devoted much time to the study of the factors which govern animal life. From our point of view the thing to be considered is how the work is likely to interest and to be of value to men whose powers of observation have been sharpened by continual use but who have not had time to devote to deep abstract thought on metaphysical subjects.

From such a standpoint we should say that many of the author's ideas are not to be grasped without considerable mental strain and even then it is difficult to be sure that one rightly apprehends them. Perhaps his meaning is not always expressed in the happiest and most lucid form, perhaps more illustrative examples of his contentions would have been advantageous, although it must be confessed that his pages are by no means lacking in these. Much space is rightly given to the subject of Natural Selection and if we understand him aright the author leans to the conviction that while this is the chief factor in the evolution of species

there may still be a residuum to be accounted for by the inheritance of acquired characters.

We feel sure that while there may be much in this book with which all will not agree, even much which all will not understand, the mental exercise of honestly attempting to master all the arguments in it cannot fail to do good.

Aseptic Duties of a Surgical Nurse or Dresser By JOHN O'CONOR, M.A., M.D. Dub., Senior Medical Officer, British Hospital, Buenos Ayres. Buenos Ayres. John Grant and Sons.

THIS little book, as the author tells us in his preface, was originally written for the use of the nurses at the British Hospital at Buenos Ayres but is now published in the hope that it may have a wider field of usefulness. It will undoubtedly, we think, be of service to nurses in out-of-the-way places, to say nothing of dressers even in large hospitals. The directions are very clearly given and the author, although not claiming that his methods are the only ones, yet gives no choice of details, for, as he very truly says, "If one has two or more methods of asepsis sepsis generally results." The book is, we believe, about to be published in England by Mr H. K. Lewis.

JOURNALS

The Quarterly Journal of Microscopical Science Edited by D. RAY LANKESTER, F.R.S., and ADAM SEDGWICK, F.R.S., and W. WELDON, F.R.S. New Series, No. 166. Vol. XLII. Part 2. London. J. & A. Churchill. 1899. Price 10s.—A notice is given in this part that the issue of the *Quarterly Journal* will not be limited as heretofore to four parts or numbers in the year, but that as there is an accumulation of material in the hands of the editors additional parts will be published at such intervals as may appear advisable. The present part contains a Memoir on the Development of the Parietal Eye and Adjacent Organs in *Sphenodon* (Hatteria), by Professor Arthur Dendy, F.L.S., of the University of New Zealand. Professor Dendy has been fortunate in securing a considerable number of the eggs of the *Sphenodon* and has extracted from them a very good series of embryos. The article is illustrated with 28 figures, showing the median eye of this lizard in all stages of development. The second article is a continuation of the memoir by Mr J. E. S. Moore on the Mollusks of the Great African Lakes in which descriptions and drawings are given illustrating the form and structure of the *Tanganyika rufiflosa*, *Melania episcopalis*, *Littorina litteria*, *Spekia zonatus*, *Nassopsis*, *Bythocaras*, and others. The next article is by Lily H. Huie who dates from the Physiological Laboratory, Oxford, and writes on the Further Study of Cytological Changes produced in *Drosera*, giving some good coloured illustrations of the changes in the cells of the *Drosera* at different periods after feeding. The last article is by Dr Arthur Willey, M.A., and is entitled Remarks on Some Recent Work on the Protochorda, with a Condensed Account of Some Fresh Observations on the Enteropneusta.

The Journal of Physiology Edited by Sir MICHAEL FOSTER, M.D. Lond., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. xxiv. No. 2. May 11th, 1899. London. C. J. Clay and Sons. Price 7s.—The articles contained in this part are: 1. W. M. Bayliss and E. H. Starling. The Movements and Innervation of the Small Intestine, with 30 figures in the text. 2. A. E. Boycott. Note on the Muscular Response to two Stimuli of the Sciatic Nerve in the Frog, with six figures in the text. 3. A. Haig, M.D. Oxon. Some Remarks on the Excretion of Uric Acid and its Relation to

mention. But it will be generally approved by the profession, as will any future action that may be taken against 'Pharmacopœia Committee,' and in favour of this movement. It is the obvious fact that the reports will be submitted to criticism and, if need be, to further investigation prior to the incorporation of the results in an authoritative work where, whether right or wrong, they must remain until a new Pharmacopœia is issued. It is even possible that when the credit and the responsibility are thus definitely assigned to individuals the work will be approached in a somewhat different spirit.

It will be remembered that in a report to the General Medical Council last November some indications were given of the probable scope of the proposed Indian and Colonial Addendum. This report has been very widely circulated under official conditions which should entail prompt attention, and already a large number of letters has been received from many of the medical and pharmaceutical authorities in India and the British Colonies. The interest which is now being shown in tropical diseases may perhaps add largely to the amount of material which must be considered by the Pharmacopœia Committee, since it is reasonable to suppose that many medical men in this country who have had experience in our colonies will be anxious to coöperate with those who are still locally engaged in active work. We gather from the report that Surgeon-General G. BIRDIE has already led the way in this direction.

LAST week, as our readers know, those who took part in the campaign on the Nile of 1896-97-98 which culminated in the battle of Omdurman, the capture of Khartoum, and the overthrow of the power of the KHALIFA, received a Parliamentary vote of thanks for their services. In the Commons the thanks of the House were embodied in the form of a series of resolutions introduced in an eloquent and excellent speech from the First Lord of the Treasury, and seconded by Sir H. CAMPBELL-BARNESMAN, the Leader of the Opposition. There was, however, one very striking and disappointing feature connected with the proceedings. The labours of the medical officers accompanying the army on the occasion in question were not recognised and the list of names of those who had rendered distinguished services did not include that of a single medical officer. The Surgeon-General upon whom the responsibility falls is the representative of the medical branch of the service, the work done was eminently satisfactory, and in the words of Lord KITCHENER, "the medical arrangements were so conducted as to afford the maximum of comfort with the minimum of suffering."

Independent statesmen his political opponents as well as his party followers generally recognise, but he was, we may assume, simply the mouthpiece of the military and War Office authorities on the occasion and followed, we regret to say, the traditional line of action where the medical service is concerned. It seems to us that the explanation which he proffered to the House in reply to Dr FARQUHARSON'S protest on behalf of the medical profession was a singularly weak and unsatisfactory one. Surgeon-General TAYLOR, upon whom the responsibility fell of directing all the field medical arrangements and who was

actioners who continue to offend against the sound and recent opposition of the profession to advertisement.

The report of the Pharmacopœia Committee to the General Medical Council touches upon many points of interest both to medical practitioners and to pharmacists, and in its opening sentence it also serves to relieve any lingering anxiety about the reception of a work marked by such radical changes. The Pharmacopœia Committee have no report upon the reception accorded to the volume, upon the steps being taken to accumulate material for the next Pharmacopœia, and upon the work which has already been done in connexion with the promised Indian and Colonial Addendum. The reception of the volume must have surprised and gratified all who remember the somewhat chequered career of former Pharmacopœias. It has been submitted to rigorous criticism without the detection of any errors of fundamental importance, but the success of a book is really to be gauged not by the criticisms but by the sale. Notwithstanding the increase in the price—an increase necessitated by the cost of production—the report states that 25,225 copies have passed into circulation and that the stock in hand is running low. These figures no doubt represent the first great rush for the new standard and it is not to be expected that they can be kept up in ensuing years, but they must have sufficed to clear the expenses incurred and to leave a margin of profit which will doubtless be applied to the preparation of the next Pharmacopœia. It is true that the circulation to a large extent depends upon the number interested in maintaining their stock in trade up to the official standard, but an important and flattering criticism, which has increased the circulation, is afforded by the official adoption of the Pharmacopœia by two colonies, Queensland and Victoria.

At the November meeting of the General Medical Council there were indications of a desire to obtain the frequent, or even constant, coöperation of the pharmaceutical societies of Great Britain and Ireland. These societies have appointed Mr O. ELLIS, Dr W. LUGG, and Mr R. J. DOWNES to confer with members of the Pharmacopœia Committee and already one conference has been held at which the chairman, Dr LEECH, presided. These meetings must add largely to the value of the next volume, since they afford opportunities for the interchange of ideas between physicians and pharmacists and for the discussion and the estimation of the value of sundry criticisms.

A most important innovation has been recommended by the Committee and adopted by the Council in connexion with the investigations in pharmacy and pharmacopœia, although such work was generally undertaken at the suggestion of the General Medical Council or of the Pharmaceutical Society, the results were considered to be credited with the good work performed. The materials supplied were duly considered and utilised and acknowledged in the preface. It is now proposed that the publication

THE LANCET.

LONDON SATURDAY, JUNE 17, 1899

THE recent session of the General Medical Council was remarkable not only for the length of time over which it extended—10 days—but for the nature of the business which occupied the attention of the members. It is becoming more and more evident that the General Medical Council is a semi public body, intermediary as it were between the State and the public on the one hand and the medical profession and its various organisations and corporations on the other. Hitherto it has kept well within the bounds of its most obvious functions as defined in the Acts and has even, perhaps, been slow to recognise all that was involved in its responsibilities, being disposed to take an easy view of its duties and to let the great profession over which (in a sense) it presides take its own course and look after its own interests and morals. The Council has now found out that Parliament did not create it for strictly limited purposes and that more is expected of it than the merely clerical duties of registration or a formal and courteous peep into the methods of examination employed by the various educational bodies. Both the Government and the profession are now looking to the Council for the solution of difficult questions and on the wisdom and moderation with which it treats these questions will depend in a great measure its future history. If it is to act effectively and withal promptly and justly it will have to procure some amendment of the Acts under which it works, while the concession of such amendments will depend on the use which the Council makes of its present powers. "To him that hath shall be given." The most serious lesson of the late meeting was the demonstration that the function of the Council is hindered by the limited and uncertain powers of the individual bodies represented so powerfully in the Council. No time must be lost in the adjustment of these powers and of the machinery for bringing them into coördination with the central power of the General Medical Council, and there is reason to hope that by November a moderate Amendment Bill may be prepared which the Government will be willing to accept, especially if in the meantime the profession displays unanimity and supports the Council in the wise use of its present authority.

In the multifarious business of the late meeting on which it is our duty to comment the first place must be given to the action of the Council in regard to medical aid associations. Whether we regard the conciliatory action of the Council in respect of medical aid associations composed of friendly societies in whose ordinary procedure the paid assessor does not appear, or its more stern attitude towards associations promoted by commercial companies and by wholesale processes of advertising and canvassing their case we cannot fail to see that the Council

has taken a large view of its powers. Therefore the Board of Conciliation has our best wishes, but we must make this proviso—that the question of wage limit be sooner or later, formally or informally, brought into the purview of the Board. But while we think so we would urge on the profession not to make this a hindrance to the constitution of such a Board. We speak with some authority on this subject. It is recognised that through our Special Commissioner we have illustrated the wide and various bearings of this question throughout the land and even in foreign countries. And we have shown that if the profession is driven to it it can hold its own and put the medical associations and friendly societies in an isolated and unfavourable position. The Board of Conciliation should end all this strife, the more so if, as the General Medical Council tells us, the leaders of friendly societies recognise the inadequate treatment of their medical officers and are anxious to deal more liberally with them. It will be time enough after the Board has been constituted to show that only by the introduction of a wage limit can fair treatment be ensured to the medical officers of these societies. In the interval between now and November the various medical, defence, and medico-ethical societies will have the opportunity of considering the whole question and of suggesting nominations for the Board. They should confer with each other and agree on half a dozen names. For this purpose the whole profession is before them, excepting the members of the General Medical Council who are excluded by the fact of their judicial functions. It is a significant fact that there was no vote taken against the Board of Conciliation in the Council. The division was between those who voted for it—20—and those who did not vote at all—eight. Our columns will be open to discussion of the best method of constructing this Board and we look hopefully towards the friendly settlement of questions which now cause much friction. Of one thing we are certain—the medical profession only wants justice.

The Council showed proper discrimination in dealing with this matter. It passed a very significant resolution in connexion with another set of medical aid associations—those promoted by commercial companies who send the professional canvasser round the town and urge the patients of other practitioners to join their associations. Dr GLOVER read to the Council a graphic illustration of this system which in some districts threatens to ruin medical practice and to demoralise practitioners who have to contend against it as well as those who profit (save the mark) by it. The Council has given notice that any practitioner who abets this system of canvassing and is proved to do so will incur its strong disapproval, and after due warning may be charged with infamous conduct in a professional respect, with its inevitable punishment of erasure from the Medical Register. It is for the medical officers of these associations to protect themselves. They would not personally canvass the patients of another medical man. It is intolerable that they should do so under cover of a commercial company. They may have acted inconsiderately. But the resolution of the Council should open their eyes, as it will leave them without pity for any punishment which they may incur. This resolution is expressed in terms of studied

of their duties, we have recognised that it is right that the committee should not seek a remedy only in the multiplication of sanitary inspectors. We have therefore written the vestry asking for the material which would have enabled us to form some opinion on the matter but have been unable to obtain it as the report is out of print. I much regret that this is the case, for while we are serious of doing full justice to the St Pancras Vestry and its special committee we are, in the absence of this evidence, unable to accept the committee's conclusions, which are widely different from those of Dr Hamer. The vestry have had in Dr Sykes an officer whose capacity and zeal are generally recognised by those familiar with sanitary administration, and the special committee's condemnation of the vestry's staff will not alone suffice to shake the confidence of the public in the officers. There is, indeed, not sufficient reason for doubting the soundness of Dr Hamer's conclusions and the only question which remains is whether the London County Council will be satisfied with the small addition to the staff which the vestry has decided to make. Judged by the reports before us we fail to see how with this addition St Pancras sanitary administration will materially differ in the future from the administration of the past.

PRECAUTIONS IN COAL-MINES

In 1894 the report was issued of the Royal Commission on

under much less risk. As was shown early in the same year by Mr Henry Hall, one of Her Majesty's Inspectors of Mines coal-dust is frequently the cause of disastrous explosions. The experiments upon which Mr Hall based his valuable conclusions related to the causes which led to the ignition of the finely suspended coal dust in the air of coal-mines. The use of gunpowder was recommended, as the flame of the gunpowder was as safe as the flame of the gas-lamp, "blowing" out the gas, rather, the latter, if rightly used, is a safe and effective method of extinguishing the gas. The use of gunpowder is recommended for the purpose of extinguishing the gas, rather, the latter, if rightly used, is a safe and effective method of extinguishing the gas. The use of gunpowder is recommended for the purpose of extinguishing the gas, rather, the latter, if rightly used, is a safe and effective method of extinguishing the gas.

explosives. This conclusion led to an express order being issued to the Home Secretary Mr. Hall not ago. Withing to his report for the year 1898 that 'it has proved success beyond all expectation and you, Sir, are to be congratulated on having initiated the legislation which has achieved such glorious results. The deaths from explosions of gas and dust for the last two years are a record of the two years together have only killed 46 persons of a figure less than that recorded for any *single* previous year. The most favourable year was 1886 when 49 persons were killed, and taking any two previous consecutive years the best were 1891 and 1892, when 111 lives were lost, as against 46 for 1897 and 1898, thus have apparently attained that which in the past has been furthering still and care at distance'. It is remarkable that "no doubt there will still be people who will prove impertinuous to the logic of these facts and they will tell us it is a mere coincidence, a fluke, and they will still try to maintain that view". One of the chief objections raised against the employment of gunpowder instead of explosives was that the formation of the evolution of consciousness came, but it appeared to me that the only complaint made about gunpowder was that the explosion used in the case of the explosion was the same as the explosion used in the case of the explosion.

CHARNOT, BILLET, DUTIL, and others were the first to point out this fact and to give isolated cases thus-treating of the same and altogether some nine cases have thus far been published. The clinical symptoms indicate an extensive affection of the motor cells of the spinal cord, every sensory symptoms being entirely absent, and in every case, with the doubtful exception of one case recorded by LAUREN in *Charité Annalen*, 1894, the diagnosis of progressive muscular atrophy, mostly of the Aran-Duchenne type, could be made. There is, however, an interesting difference among these cases as to their relation to previous infantile paralysis. Thus, in CHARNOT's case, for instance, the infantile paralysis affected the lower extremities, while the later disease began in the muscles of the shoulder. In other cases the atrophy of the later (adult) disease started in the parts previously affected as well as in the healthy parts, while in LAZARUS' case, in which the polymyositis had affected both right extremities and a small portion of the left leg, the later disease was strictly confined to the muscles of the same parts.

The pathogeny of the later disease was generally accepted in the form propounded by CHARNOT, according to whose views there existed in some individuals a certain disposition, a kind of vulnerability of the ganglion-cells of the anterior horns which at one period of life might give rise, under the influence of morbid agencies, to an acute anterior poliomyelitis and at another and later period to a progressive muscular atrophy, the two diseases being thus manifestations of a single and fundamental original morbid condition. Further, the originally damaged parts, though apparently restored to health, might under later attacks of illness reveal themselves also as fresh foci of disease. This view has been accepted by BILLET, DUTIL, GRIFFITH, and others and seems to accord best with known facts.

THE SANITARY CONDITION OF ST PANGRAS

— "No gold mine."

In our last two issues we have referred to a report by Dr. Hamer, assistant medical officer of health of the London County Council, on the sanitary condition of St. Pancras and to a report by a special committee which was appointed by the vestry of St. Pancras to inquire into the subject matter of Dr. Hamer's report. Dr. Hamer had found in St. Pancras many insanitary conditions requiring remedy and had come to the conclusion that a committee, however, has recommended the appointment of only two additional inspectors and has we must presume, satisfied itself that its existing staff is numerally sufficient to deal with the conditions which Dr. Hamer has pointed out. The committee has laid stress on the "demonstration" of the sanitary staff has referred to their "discontent" and "absorption" and, in so far as these "demonstrating" instances have prevented the proper carrying

2. Alle les uns, Polémiques et les autres
3. L'opéra du Maréchal

in command of his own branch of the service, has, the rank of a general officer, the distinction between combatants and non combatants has moreover been abolished by recent regulations, and we should therefore have thought that the Government would have seized the first opportunity of giving practical effect to their own measures. It is all very well to talk of the great and distinguished profession to which the honourable Member for West Aberdeen belongs, but why should every opportunity be neglected of showing that it is so regarded? If the custom of the service be such as that laid down in the House of Commons all we can say is that it is a custom to be more honoured in the breach than in the observance and the sooner that the tightness of this piece of red tape be loosened the better. The army medical services admittedly did excellent, very arduous, and long sustained work in Egypt, without which Lord KITCHENER and his troops would never have accomplished what they did, and medical officers naturally expect to receive the thanks of Parliament in common with other officers by the selection and inclusion of the name of one of themselves in the list.

Now that we are touching upon this subject, we may add that the amount of work and responsibility which fell to the lot of the medical services during the late campaigns on the North West frontier of India in 1897-98 was enormous. Whether those expeditions were politically wise or not, or whether all the generals did their work equally well, are matters of opinion with which the medical services have nothing whatever to do. We have never heard, however, at there was any failure in the field medical organisation or in the provision of hospitals and a hospital service on a very large scale, but the Surgeon General of Her Majesty's Forces in India upon whom all the labour and responsibility devolved cannot be said to have been extravagantly rewarded by having the honour of a Companionship of the Bath conferred upon him.

DURING recent years the investigation of the life histories of certain diseases, notably of the nervous system, has gradually brought about a conviction that the starting-points in the etiology of nervous diseases in an adult must sometimes be looked for in the affections of childhood in which the nervous system has been involved. In the *Journal of Nervous and Mental Disease* (May, 1899) Dr WILLIAM HINSON gives very full records of an interesting case and calls attention to the fact that infantile spinal paralysis may give rise to spinal disease in later life. The case is as follows:

A man, 45 years old, a tailor, and free from indications of syphilis, twice married and in the enjoyment of perfect health up to three years previously, began at first to notice a stiffness and weakness in the left leg which gradually became worse. After some time the right leg also became affected. He soon became unable to use his leg in working his sewing machine and he was not able to stand or walk for any length of time. The upper extremities remained unaffected and there were no sensory symptoms whatever. The functions of the bladder and rectum were unimpaired and sexual power was not diminished. Examination revealed an atrophy of some of the trunk and shoulder muscles and especially of the deltoid,

supra spinatus, and infra spinatus of the right side. These muscles also exhibited fibrillary tremors and the reaction of degeneration. There was no atrophy in the muscles of the lower extremities and their electrical reactions were normal. The knee-jerks were exaggerated and there was ankle clonus on both sides. The plantar, cremasteric, and abdominal reflexes were present. The reflexes in the upper limb were not increased. Sensation to touch, pain, and temperature was normal in all parts of the body and the muscular sense was unimpaired. Both speech and pupillary reactions were normal and the ophthalmoscope revealed nothing abnormal. Besides the atrophied shoulder muscles above mentioned there was marked atrophy also in the biceps, triceps, and pectoral muscles, also on the left side. (It appears that when the patient was a child of two years of age he had an attack of infantile paralysis which left behind a partial atrophy of the left upper extremity.) The lower limbs now gradually became more spastic and rigid so that within a few months he was unable to walk at all and he began to suffer from shooting pains in the legs. These pains were so intense that he had to be given hypodermic injections of morphia at frequent intervals. Both sets of symptoms progressed in severity and he became completely bedridden. The lower limb muscles atrophied and assumed a condition of marked contracture (extreme extension and adduction), and a progressive paralysis of the upper limbs also now supervened till both arms were completely paralysed and only the fingers and one wrist could be moved at all. Cutaneous sensibility was retained and the functions of the bladder and rectum were unaltered. He now developed a bulbar paralysis with difficulty of swallowing and died without developing any other symptoms.

The necropsy which was made eight hours after death showed the following changes in the nervous system. The brain seemed normal in colour, consistency, vascularity, and general appearance. The bulb and spinal cord, however, showed changes and on microscopical examination the following lesions were found. The cervical cord from the second to the fifth segment showed a considerable atrophy and destruction of the cells in the left anterior cornu, with dilatation of pericellular and perivascular lymph spaces and proliferation of blood vessels. There was marked degeneration in Goll's column, especially next the septum. On the right side similar changes but to a far less extent were present. In the fifth, sixth, and seventh cervical segments similar changes were found and in addition a degeneration in the lateral columns (pyramidal tracts) most marked on the left side. At the eighth cervical segment (which supplies the fingers) the grey matter and most of the cells appeared to be normal, the degeneration being limited to the white substance (pyramidal tract). In the dorsal segments there was much diffuse degeneration throughout all the grey substance and at the seventh dorsal segment the degenerations were so extensive that they had the aspect of a transverse myelitis. In the lumbar cord the degenerations were still abundant, but less so in the right half, which contained a fair number of undestroyed cells. Finally, the bulb showed marked degeneration and loss of cells in the hypoglossal, vago-glossopharyngeal and ambiguous nuclei, and in adjacent parts of the substantia reticularis.

dinner which took place on June 8th at the Trocadero Restaurant. The President of the Institute, Dr. Thomas Stevenson, was in the chair and there were present representatives of the Board of Agriculture, certain of the Presidents of the learned societies, and several distinguished men of science. The progress of the Institute was the subject of the many speeches which were made. We cordially join in congratulating the Institute on this progress and not the less because it aims at raising the chemical profession to the same level of dignity as other learned professions.

THE CASE OF DOCKRELL & DOUGALL A TESTIMONIAL TO DR DOCKRELL

READERS of THE LANCET will remember the details of this case and that in extending our sympathy to Dr Morgan Dockrell in the matter we felt bound to record a protest

and do not, against the treatment which he had received. We did not, after the judges in the Appeal Court really understood the deep importance of the matter at issue. We are therefore glad to learn that a testimonial fund has been started with the object of making a presentation to Dr Dockrell "which" to quote the letter of those responsible for the movement, "shall express the admiration of his medical brethren for his courage and public spirit and in some measure recompense him for the very heavy costs in which he has been mulcted." The case involves a principle of the highest importance to all our readers, for Dr Dockrell's two attempts to secure by law the exclusive right to control the use of his own name were made in the interests of every member of the profession. We hope, therefore, that many favourable responses will be sent to Mr Ernest Clarke, 3, Chandos street, Cavendish-square, W., who is acting as honorary treasurer of the fund.

VITAL STATISTICS OF THE BURGH OF GOVAN

THE burgh of Govan on the Clyde is fortunate in numbering among its inhabitants a member of our profession who possesses the inclination as well as the ability to prosecute an independent and laborious inquiry into the causes of mortality in that burgh. Dr W. G. Barras of Bellahouston has forwarded to us a copy of a lengthy report which he has recently presented to the provost, magistrates and commissioners of Govan, in which he gives very complete particulars of the local vital statistics, and he has been careful to make his book as interesting as possible to dwellers in parts of the kingdom which are remote from Govan by the addition of a valuable introduction which gives a general and topographical history of the burgh from very early times. On the authority of Fordon we learn that the first historical reference to Govan dates back to A.D. 565, in which year a monastery was founded there by Constantine, of which he was the first abbot and in which he was buried after having suffered martyrdom. As early as the sixteenth century Govan, or Little Govan as it was then called appears to have ranked among the largest towns of Scotland. At the period referred to what is now the flourishing city of Glasgow was no more than a village situated above Govan on the Clyde both places owing their prosperity to the coal and iron industries of Lanarkshire, aided, of course, by their commanding position on the banks of a navigable river. Govan at its largest was a hamlet numbering but a few hundred inhabitants, mostly engaged in agricultural pursuits or in supplying the Glasgow market with fruit and vegetable. Another of its staple industries was that of salmon fishing, for which it was long famous, and this occupation was continued down to a period within the memory of persons still alive. In the first decade of the

the pressure of poverty or of vice and the other survivals of savagery which remain in it, cannot always be trusted even with its own most natural change. We may hope that ultimately the moral forces which have refined the manners of a majority will be able to civilize the mass and that cruelty will become practically extinct. In the meantime, however, it will be happily furnished with the instruments of law, must be allowed to operate for the protection of the weak against the strong and brutal. Among the most efficient of such instruments is the National Society for the Prevention of Cruelty to Children which needs no stronger commendation than the record of its doings.

THE APPROACHING ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

MONDAY, June 12th, was the last day on which the nominations of candidates for the two vacancies on the Council could be received and the names of four candidates have been given in. The two vacancies arise from the terms of office of Mr T. H. Jessop of Leeds and Dr Ward Cousins of Southsea having come to an end, these two gentlemen, however offer themselves for re-election and the two other candidates are Mr H. W. Page, surgeon to St Mary's Hospital, London, and Mr Jordan Lloyd of Birmingham. The election will take place on Thursday, July 6th, and voting papers will be sent to all Fellows in the British Isles. It will not be necessary to apply for them, Fellows may, if they prefer it, vote personally.

THE INSTITUTE OF CHEMISTRY

AFTER some years of struggle the Institute of Chemistry has at length attained an importance amongst examining bodies which is now being generally recognized. The Institute of Chemistry was founded with the object of conferring some qualifying mark upon those following chemistry as a profession. It was not until 1885 that a Royal Charter was obtained, in consequence of which the Institute rapidly assumed the position of a governing and examining body comparable in character with those of the medical profession. The examinations, which are thoroughly practical in character, have been brought up to a high standard, while amongst other worthy aims not the least commendable is that of establishing a code of professional conduct. The Fellows of the Institute now number nearly 1000. The examination laboratories were especially designed some years ago for the practical examination in the premises of the Institute in Bloomsbury square. Each candidate presenting himself for examination must first satisfy the examiners that he has been through a thorough course of systematic study at an institution of recognized educational standing. We have frequently referred in these columns to the fact that no definite qualifications or simply stated that he must be a person possessing competent knowledge, skill, and experience, without any Act are required. In a clause in this Act it is the public analyst appointed under the Food and Drugs Act are required. In a clause in this Act it is referred to the possession of a diploma. We have consequently reported that the Fellowship of the Institute of Chemistry might meet the case. As a matter of fact, the Local Government Board have comparatively recently announced that they will accept the qualifications of Fellowship and Associateship of the Institute of Chemistry as satisfactory evidence of competence in chemistry, and in order to meet the further requirements of the Board have lately decided to establish an examination in therapeutics, pharmacy, and microscopical anatomy. That the Institute of Chemistry is well supported was evident on the occasion of its last annual

that in regard to fumes gunpowder is worse than the nitro-explosives and Mr Hall quotes an example of a gunpowder pit which he inspected where the fumes were so thick and blinding that the manager lost his way and he had some difficulty in finding it again. We expressed the opinion in these columns more than five years ago that if the recommendations of the Royal Commission could be put in force without delay there would be little doubt that the risk of explosions in coal mines would be greatly limited. Soon after the report of the Royal Commission was issued a terrible explosion occurred in the Albion Colliery in South Wales by which nearly 300 lives were lost. This was known to be a fiery and dusty mine and it was not certain whether the preventive measures of using exclusively high explosives for "blowing-out" purposes and of keeping the mine watered had at that time been taken. Mr Hall's report deals with only one colliery district, the Liverpool district, and it is to be hoped that the reports from other districts may be equally satisfactory. We imagine that this must be the case, for happily we have heard less frequently of late of those frightful disasters to which the colliery districts are liable. If so, the importance of the experiments which suggested the preventive measures indicated and now enforced cannot be too highly estimated.

TYPHOID FEVER IN HOLBORN-CIRCUS

DR SEDGWICK SAUNDERS, the medical officer of health of the City of London, in his report on the health of the City for the five weeks ended May 27th, 1899, gives an account of an outbreak of enteric fever in a large business house in Holborn circus which presents points of some interest. The outbreak occurred between Jan 23rd and Feb 16th and during that time 53 of the inmates were attacked, the greatest number of cases in any one day being eight. The total number of persons employed in the establishment was 620, but of these only 416 slept on the premises, though an additional 71 took dinner and tea in the establishment. The attacks were apparently confined to the 416 persons who resided on the premises, there being, it seems, no cases among the remaining 204. In other words, the 416 residents were presumably exposed to some conditions which were foreign to the remaining 204. Dr Sedgwick Saunders has been unable to discover any connexion between the outbreak and polluted water or milk, and although the inquiry is still incomplete suspicion appears to attach to the drainage system which is manifestly defective. There would, however, be a difficulty in explaining the outbreak by a thesis of this nature since the exemption of the 204 non residents would militate against its acceptance. The outbreak has, too, some of the characters more commonly associated with specifically polluted food of some kind than with one due to drainage defects. The sex distribution of the attacks does not throw much light on the matter, as although but five females were attacked the percentage incidence on males was but slightly in excess of that upon females, a circumstance which in itself tends to discredit a view that contaminated milk was the cause of the outbreak. Bacteriological examinations were made by Dr Washbourn of specimens of water, milk, and butter, but with negative results and clearly but little value is to be attached to bacteriological investigations in an outbreak of this kind, since the specific pollution of whatever may have been the causative agent was evidently of a transitory nature, indeed, it is even possible that all the cases may have been infected before the first of the group was recognised. Evidence must be sought for rather in the distribution of the cases and in a detailed examination of the several articles of food consumed by those attacked as contrasted with those who escaped. Dr Sedgwick Saunders acted with great promptitude and at once took all precautionary and preventive measures. The milk was sterilised

and the supply was changed, the water cisterns and mains were cleansed, and the patients were rigidly isolated and carefully nursed, the fatality rate amounted to 11 per cent.

THE BIRTHDAY HONOURS

In the list of birthday honours which we published last week we inadvertently omitted two names—those of Dr John Sibbald, M D Edin, F R S Edin, &c., and Major William Babbie, R A M O. Dr Sibbald, who lately retired from his position as Commissioner in Lunacy for Scotland and who is well known as an authority in questions connected with lunacy, particularly with regard to administrative matters, received the well deserved honour of knighthood. Major Babbie has been made a O M G in recognition of his services in Crete in connexion with sanitary matters. We congratulate Sir John Sibbald and Major Babbie, O M G, and regret the week's delay in the expression of such congratulation.

A SINGULAR CASE OF MASTOID ABSCESS

It is a generally accepted fact that the cells in the mastoid process do not develop until after the third year of life and it follows that mastoid abscess of the kind found in the adult is practically unknown in infancy. An apparent exception to this rule is quoted in the *Journal de Clinique et de Thérapeutique Infantiles* of June 1st, 1899. The case was reported by Dr Lermoyez to the Société Française d'Otologie, Laryngologie, et Rhinologie and was that of a child, aged two and a half months. The starting point of the trouble as usual was an acute purulent otitis. After three weeks an abscess was found beneath the upper extremity of the sterno-mastoid. A cavity in the mastoid process full of carious bone and pus communicated on the one hand with the mastoid antrum and on the other by a small opening in the digastric fossa with the abscess just described. The whole end of the process was removed, the cells and antrum were cleared out, and the child was well in six weeks. This morbid condition which is known in France as the mastoiditis of Bezold is very rare if not unique in an infant and its occurrence almost at the time of birth is of equal interest to the anatomist and the surgeon.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN

FROM details recently published we are pleased to note that the progress of this society during the past year has been satisfactory. The net income has amounted to £51,319 as compared with £47,917 in the previous year, and it is a significant fact that the increase from ordinary contributions alone is £4925. The expenses for all purposes amount to £52,773 as against £53,000 for the year before. These proofs of the society's continued popularity and of the economy observed in its administration are not discounted by the measure of success which has attended its efforts. As many as 28,165 cases of alleged improper treatment have been investigated. In 21,096 of these, with some unavoidable exceptions, the offenders were cautioned and in 18,223 cases subsequent supervision showed that the warning had been effectual. In 2873 cases the offenders were prosecuted, a conviction being obtained in 96.27 per cent of this number. By far the most prevalent forms of cruelty, as we have had occasion to note before, are neglect and starvation. These together account for 21,755 of the whole number of wrongs recorded. Ill treatment and assault come next with a total of 3748, then 1240 cases of exposure for begging purposes, then various less common forms of evil doing. It is therefore abundantly proved even by the statistics of a single year that human nature, exposed to

sub-conscious state is not at all uncommon in the post-epileptic stage. The condition is in many respects like that in somnambulism. Both bigamy and perjury (one case each), given in the above list, show that these offences may be committed by epileptics in the automatic stage where the patient loses all recollection of his previous history or surroundings after a fit, and, moreover, that such a condition of amnesia and alteration of personality may in some cases persist for a considerable time (days or even months) before recovery (which may sometimes, also, be equally sudden) takes place.

DEATHS UNDER ANÆSTHETICS

A DEATH under chloroform occurred on April 18th. The patient, a woman, aged 24 years, was to be operated upon for varicose veins at the Stanley Hospital, Liverpool. A "very slight dose" was given, unusual excitement appeared towards the end of the first stage of anaesthesia, and respiration stopped. We are not informed what method was employed, what was the duration of the anaesthesia, or who administered the chloroform. It would appear that an overdose was taken during the patient's struggles and the respiratory centre was paralysed. Dr David Morgan of Liverpool favours us with a brief note of a death under chloroform which occurred in Liverpool on April 6th. The patient, aged 72 years to a "decachem" of chloroform. The eyeball was removed and cardiac syncope occurred, proving fatal. Did this patient die from chloroform or because she had too little chloroform? Unless the nature of such cases furnish needless to speculate upon the cause of death. Cause must antipate effect and there is no doubt a very adequate cause, for death under chloroform can always be traced. The records of such cases would only reason out the facts and help their fellow practitioners by care fully and logically detailing their experiences. A death which occurred recently at St. Mary's Hospital illustrates the extreme difficulty of deciding whether chloroform can be safely administered for either in the later stages of an operation. The patient, a woman, aged 34 years, suffered from malignant disease of the mamma and was given ether with a view to removing the breast. During the progress of the anaesthesia some coughing occurred and chloroform was therefore substituted for ether. The patient's colour changed, a rescopy was held and she died apparently from circulatory failure. A post-mortem examination of the heart was found to be fatty. A post-mortem examination of a patient who died under an anaesthetic at King's College Hospital recently showed masses of undigested food in the stomach, some of which had entered the trachea and bronchi causing suffocation. The patient, a worker at a newspaper office had his arm broken by machinery and he was taken to the hospital to have his injuries treated. As he had had a heavy meal he was allowed to wait two hours in the hope that his food would become digested. The A.C.E. mixture was given with the result mentioned above. In the case of a healthy man surely lavage or a hypodermic injection of apomorphine to empty the stomach is a safer proceeding than inserting the risks of vomiting during semi-anaesthesia. In the present case large masses of meat had passed into the air passages. A fatality under chloroform is reported as having occurred at the Ophtalmic Hospital, Gray's Inn road. The patient, a man, aged 41 years, was placed under chloroform by the house surgeon for the removal of a diseased eye. At the commencement of the operation the patient died suddenly. We have no particulars to guide us in attempting to explain the death. The same remarks apply to the death of a child, aged 16 months which occurred at the Charing-cross Hospital on May 8th. Two deaths in military hospitals of troops are reported from Kilrea and Dublin.

CHANGES IN THE SALIVARY GLANDS IN DIABETES

IN the *Boston Medical and Surgical Journal* of May 18th Dr H. F. Harris has published an interesting paper on this comparatively unknown subject. His attention was first directed to a possible relation between morbid conditions of the salivary glands and pancreas by the following cases in which diabetes followed mumps. The patient was a farmer, aged 42 years, who had had no illness until an attack of mumps three years before. About a month after recovery he noticed that he was passing more urine than formerly, and since then the increase had slowly but steadily progressed and the other symptoms of diabetes appeared. He was much emaciated and passed in the 24 hours 6440 cubic centimetres of urine containing 4.6 per cent of glucose. His subsequent history is unknown. The writer found in literature several references to the fact that diabetes sometimes follows mumps. He also ascertained that by the removal of all the salivary glands in a dog slight transient glycosuria could be produced—a conclusion which had been previously established by Reale (Congress of Berlin, 1890). Furthermore, the latter experimenter produced glycosuria in this way in dogs when he had failed to do so by removing the pancreas. Since the publication of the pancreas the possibility of pancreatic disease arising from mumps has been admitted, but there is some doubt as to the nature of the case to which he referred. Dr Harris could not find another case of pancreatic disease due to mumps. But when it is remembered that sublingual and submaxillary adenitis, orchitis, prostaticitis, ovariitis, mastitis, nephritis, and thyroiditis, have been observed, it seems probable that a gland so closely resembling the pancreas as does the pancreas would at times be involved. If so, as in the parotid and testis, atrophy might ensue. That functional alterations in the salivary glands occur in diabetes has long been known, but the condition has received little attention from clinicians and pathologists. The following case shows that profound changes sometimes occur in the pancreas. A man, aged 63 years, died from diabetes complicated with pulmonary tuberculosis and gangrene of

current century handloom weaving was the chief industry of the village, but about the year 1850, when ship-building began to revolutionise the trade of the district, Govan suddenly sprang into importance and in the year 1864 it acquired the dignity of a burgh. Ever since that date the town has rapidly and steadily increased in size, until at the present time it stands seventh in the list of large Scottish towns and contains a population of nearly 73,000. In the course of the last 35 years, which is the period covered by Dr Barras's inquiry, the mortality of Govan, like that of Glasgow and most other large towns in England and Scotland, has varied considerably. The mortality reached its highest point in 1864—namely, the year of incorporation—when it amounted to a rate of 33.2 per 1000, it was lowest in the year 1894 when the rate fell to less than half, or 15.5 per 1000, the rate in the entire period of 35 years having averaged 22.5. The tables which illustrate Dr Barras's report are systematically arranged, the classification adopted being that of the Registrar General, and a useful summary is inserted giving a general idea of the teaching of the tables, without this summary the entire report would lose much of its value and interest to the general reader. In the first of his tables Dr Barras shows the mortality from all causes and also from infectious diseases in quinquennial periods from the year 1864 onwards. From this table it appears that there has been a marked decrease in the later five year periods as compared with the earlier, both in the deaths from all causes and in those from diseases of the zymotic group. Calculated on the present population of 73,000 the difference between the mortality in the first and in the last quinquennium represents a saving of 803 lives per annum. Taking the average for the 10 years 1889-98 it appears that Govan has shown a death rate which is lower than that of all Scotland and also lower than that of the eight principal towns in the aggregate. Considering the occupation of its inhabitants and the conditions under which some of them live such a rate reflects great credit on the local public health department, who are evidently doing their utmost to improve the health and prolong the lives of the people. In quoting the mortality at ages under five years and above 70 years Dr Barras puts the rate at 12.1 and 1.2 respectively per 1000 of the population. We presume, however, that the deaths at these ages are calculated on the total population and not on the population at corresponding groups of ages as is the case in England, for otherwise it would be difficult to understand how the above exceptionally favourable proportions could have been arrived at. As regards the prevalence of particular forms of disease Dr Barras has much to say which is highly important but mainly of local interest, there is nothing which calls for particular comment in the incidence of the ordinary infectious diseases and his remarks on diseases of the constitutional and other principal classes, although of great importance to the people of Govan, are scarcely of sufficient general interest to need special notice in our pages.

TYPHOID CHOLECYSTITIS

In recent years cholecystitis in typhoid fever has attracted some attention. But although it was observed as long ago as 1836 by Louis only a limited number of cases have been recorded. This complication seems to be commoner than might be supposed,¹ but it rarely gives rise to distinctive symptoms. In the *American Journal of the Medical Sciences* for March Dr O. Camac has published the following case which was under the care of Professor Osler at the Johns Hopkins Hospital. The patient was a coloured woman, aged 24 years, who was admitted to hospital after an illness

of three weeks' duration marked by sudden onset, with headache and chill, vomiting, epistaxis, and abdominal pain. The chill recurred every day. On admission the temperature was 104° F. 13 intensely green watery stools were passed in one day. The abdomen was not distended or tender. On the fifth day abdominal tenderness was noticed for the first time, particularly in the right upper quadrant, where there was also dulness. About nine centimetres below the costal margin and about three centimetres from the umbilicus a rounded, fairly resistant mass was felt. In consequence of the profuse diarrhoea amoebic abscess was thought of. The Widal reaction, however, was well marked at a dilution of 1 to 70. Typhoid cholecystitis was suspected. As a means of diagnosis a long hypodermic needle was inserted into the mass, it drew off about 15 cubic centimetres of a clear urine like fluid. The patient became more comfortable. Numerous motile bacilli suggesting typhoid bacilli were found in the fluid. As there was no evidence of suppuration operation was deferred in the hope of resolution. On the following day the patient was worse. There was great tenderness in the right hypochondrium and she was apparently suffering pain. In view of the relief afforded in Mason's case² a second puncture was made at the same point. But the tumour was not to be felt and only blood was withdrawn. Laparotomy was then performed by Dr Cushing. The gall bladder was greatly distended, the surface was dark green, the vessels were injected, and there were a few fibrous shreds at one spot. After the gall bladder had been loosely attached to the abdominal wall 120 cubic centimetres of fluid similar to that previously withdrawn were aspirated. On opening the gall bladder no necrotic area was found. A drainage tube was inserted and the wound was partially closed and packed with gauze. Death occurred on the following day. At the necropsy Peyer's patches were found to be congested and ulcerated. Dr Camac appears to regard laparotomy as the best treatment in these cases, but he admits that the results are probably as bad as in cases not operated on. Tapping he deprecates as likely to lead to peritonitis.

CRIMES COMMITTED BY INSANE EPILEPTICS

THE mental alienation associated with epileptic insanity often carries with it tendencies to violence, brutality, and crime. The epileptic is prone to such excess at two particular periods of the disease—viz. (a) during an attack of so-called "psychical" epilepsy (epileptic furor), or (b) in the post epileptic automatic stage succeeding severe fits. It has generally been noted that as regards acts performed by the patient in the latter stage there is but little or no recollection of the deed when the patient has recovered from this condition of temporary mental automatism. Hence crimes committed by epileptics have important medico-legal aspects. In the *Transactions of the American Medico-Psychological Association* (1898, p. 203) Dr H. E. Allison gives a valuable record of observations made by him on this subject based upon cases admitted to the Matteawan State Asylum. Out of 2080 insane offenders committed to this institution there were 70 epileptics convicted of crimes as follows: for assault, 16, for larceny, 14, for murder, 11, for burglary, eight, for robbery, rape, and forgery, four each, for arson, two; for unnatural crimes, two, and for bigamy, mayhem, perjury, vagrancy, and injury to property, one each. It will be seen that crimes against the person in the form of assault, murder, rape, unnatural crime, and mayhem constitute a total of 34, or almost exactly 50 per cent of all the offences, and that assault and murder are the commonest forms of crimes against the person committed by epileptics. It is to be noted that vagrancy occurs but once, yet there can be no doubt that the act of wandering at large in a dreamy,

¹ THE LANCET, June 12th, 1897, and July 9th, 1898.

² THE LANCET, June 12th, 1897.

Journal of Public Health Within two years of this we find Dr Brehmer at Göbersdorf opening the first sanatorium on a carefully thought out organization. From this point the success of the treatment has been continuous, and we are preparing to welcome back into England a system which we ought to have accepted and developed nearly 60 years ago. Probably others before Dr Bodignon have at various times advocated the rational treatment of consumption, but he is the first whose advocacy though bitterly opposed was successful in gradually, if slowly, changing the whole current of popular and medical opinion on the subject. One of his patients whose case he describes in his book, a young lady in the third stage of consumption, whom he treated in 1837, is still living at Cheltenham, a grateful witness of his skill.

IMPORTANT DECISION AS TO INFECTIOUS DISEASES

AN important case known as that of "Warwick v. Graham" was decided on June 11th by Mr Justice Day in appeal against the interpretation put upon Section 124 of the Public Health Act, 1875, by two justices for the county of Cumberland. The section deals with the power of compulsory removal of a sick person to a hospital for infectious diseases. It has often been held that, although the section allows of such removal by order of any justice when the person suffering from an infectious disease "is" in the section, a such accommodation has to do with the welfare of the patient and not with the protection of other persons. This view is taken because the clause further states that one of the conditions under which the removal may be effected is that the sick person "is" lodged in a room occupied by more than one family. This has been held to imply that protection against infection is not contemplated in the section so long as members of only one family are in the house. But others have contended that the use of the word "or" in the section shows that there were two different sets of circumstances, in either of which removal of the patient under a magistrate's order could be carried out, and, further, it has been urged that the general intention of the Act is not the welfare of the individual but that it has concern with the public health and hence with the protection of the public against infection. Magisterial decisions have varied accordingly as one or other of these views has been pressed upon the justices, but hitherto no decision on appeal has been available for general guidance. In the case in question a boy in Workington was suffering from scarlet fever and it was not pretended that he had not proper lodging and accommodation as was necessary for his own welfare, but the corporation insisted that, owing to the position of the room which the patient occupied with respect to other rooms in the house, including the kitchen, it was impossible to isolate him in the sense of preventing the spread of infection to others. The magistrates declined to regard Section 124 as applicable to such a case. They held that the proper lodging and accommodation which was necessary furnished no more than that the patient was provided with ordinary habitation, clean, and comfortable quarters such as are requisite for a sick person, and they refused to grant an order of removal to hospital. This decision was appealed against and although I have not yet before us the revised judgment of Mr Justice Day the brief account of it already published shows the case to be of sufficient importance to warrant our calling immediate attention to it. For the judgment on appeal is to the effect that Section 124 was clearly directed to the protection of persons from infection and not merely to the protection of the sick person himself. This judgment is in accordance with common sense, it is in accordance with the general necessities

of the case as set out again and again by medical officers of health, but it is opposed to a number of opinions which have been given by legal members and officers of different sanitary authorities. This difference of opinion has now prevailed ever since the Act of 1875 was passed, it has in many cases hindered the proper administration of the law against the spread of infection, and therefore we are glad that a decision has at last been given which must be regarded as settling the matter at rest.

"CRUELTY TO WOMEN"

THE temperance and wisdom which characterized the proceedings of the first meeting of the League which has just been formed to secure seats for women in shops and of which the Duchess of Westminster is president afford a good omen for the realisation of the necessary reform which the new League has at heart. Since this meeting, which was held under the presidency of the Dean of Westminster in the Jerusalem Chamber on the 8th inst, the Seats for Shop Assistants (England and Ireland) Bill has passed through committee, has been reported without amendment to the House of Commons, and has been read a third time. There is reason to hope, therefore, that the realisation of the wishes of the kindly ladies who form the League is near at hand. That in some cases women should be compelled to stand in shops for from 12 to 14 hours daily with only two intervals of half an hour for dinner and 20 minutes for tea all the year round regardless of temperature is a standing disgrace to a country like England, and this is emphasised by the fact that in New Zealand a law already exists by which an employer is rendered liable to a penalty if he does not provide seats for his female assistants. It is unnecessary to point out to our readers either the harm that is done to the women or the lessened capacity for work which is the outcome of thoughtless employers by employers in this connection. The present Bill before the House deals with England and Ireland only and it will be remembered that the Lords have recently thrown out a Bill on the same subject dealing with Scotland. It is to be hoped, however, that legislation will not eventually be restricted to any particular divisions of the United Kingdom. At the meeting above referred to it was unanimously resolved that efforts should be made to form an advisory committee composed of medical men and the proprietors of shops and that the wives of proprietors of some of the shops should be asked to join the League. With this suggestion we are in full accord and we heartily wish success to a movement which we have always strongly supported.

CHINESE PREVENTIVE MEDICINE!

WHETHER it be from the fact that the Chinese physicians consider that man is influenced by heat and humidity, the harmony of which constitutes life, or whether it be that they consider the human body as a harmonious instrument which is affected by the vibration of the muscles, tendons, nerves, and arteries, we know not, but the Sanitary Board of Hong Kong has just had a curious application made to them for permission to hold a procession of a somewhat corporant nature to frighten away the plague which is increasing in Hong Kong, though we are glad to learn from a correspondent that it remains localised in No 9 hospital district, a part of the town rarely visited by Europeans. As was pointed out by Dr Atkinson, principal civil medical officer, it is certainly not advisable for large crowds to gather in a part of the town affected with the plague, but the application was granted on the understanding that the firing of crackers and the beating of gongs should cease at nine o'clock in the evening, moreover, no noise was to be made within a certain distance of the

the foot The body was much emaciated The pancreas was found to be very small, weighing only 35 grammes It was hard and nodular and on section showed numerous fibrous bands There was evidently atrophy secondary to old interstitial pancreatitis All the salivary glands were small Microscopically both the pancreas and salivary glands showed identical changes There was marked thickening of the trabeculae which bind the lobules together In some parts all the nuclei of a lobule were destroyed and replaced by newly formed fibrous tissue The parotid acini had a diameter from 10 to 20 μ (In a normal parotid the diameter was from 20 to 25 μ) Microscopical examination of the other organs showed them to be normal

PRESENTATION TO MR G A SYME OF MELBOURNE

MR G A SYME of Melbourne, whose approaching marriage has been taken advantage of as a fitting opportunity to testify to the esteem and honour in which he is held by his brother practitioners in Melbourne, was entertained at the Vienna Café in that city on May 4th, when he was presented with a piece of plate In a congratulatory letter his fellow practitioners, after referring to his personal qualities and his surgical ability, address him as a representative and leading man of the profession No such compliment has previously been paid to any of the younger men in Melbourne and the occasion was made the more interesting by the circumstance that Mr Syme was quite unprepared for such a demonstration of regard and affection His work as a teacher both at the university and at the Melbourne and other hospitals has given him a wide area of influence and has gained him a great reputation for accuracy and thoroughness as well as for lucidity of thought and expression Mr Syme is to be congratulated on having earned such a demonstration of goodwill on the part of his *confreres*

THE SANITARY INSTITUTE

THE preliminary programme of the Eighteenth Congress of the Sanitary Institute, to be held in Southampton from August 29th to Sept 2nd, has now been issued and includes three general addresses and lectures Three sections will meet for two days each dealing with Sanitary Science and Preventive Medicine, presided over by Sir Joseph Ewart, M D St And, Engineering and Architecture, presided over by Mr James Lemon, M Inst C E, and Physics, Chemistry, and Biology, presided over by Professor Percy F Frankland, F R S There will be also eight special conferences—viz Municipal Representatives, presided over by Alderman T Walton, Chairman of the Southampton Health Committee, Port Sanitary Authorities, presided over by Mr Millar Wilkinson, Chairman of the Port of London Sanitary Authority, Medical Officers of Health, presided over by Dr T Orme Dudfield, Medical Officers of Schools, presided over by Dr C E Shelly, consulting medical officer to Haileybury College, Engineers and Surveyors to County and other Sanitary Authorities, presided over by Mr E P Hooley, Veterinary Inspectors, presided over by Mr W Hunting, Sanitary Inspectors, presided over by Mr C MacMahon, chief sanitary inspector at Torquay, and Domestic Hygiene, presided over by Mrs Patey The local arrangements are in the hands of an influential committee, presided over by the Mayor of Southampton, with Mr A Wellesley Harris, M R O S Eng, Mr W B G Bennett Assoc M Inst O E, Mr W Matthews, M Inst O E, and Mr C H Russell, M R O S Eng, as honorary secretaries The President of the Congress is Sir W H Preece, K O B, F R S, Pres Inst O E Mr Malcolm Morris will deliver the inaugural lecture, and Bailie J Dick, chairman of the Health Committee, Glasgow, will deliver the popular lecture

We understand that over 300 authorities, including several county councils, have already appointed delegates. In connexion with the Congress a health exhibition of apparatus and appliances relating to health and domestic use will be held as a practical illustration of the application and carrying out of the principles and methods discussed at the meetings It not only serves this purpose, but also an important one in diffusing sanitary knowledge among a large class who do not attend the other meetings of the Congress

THE STUDY OF TROPICAL DISEASES IN GERMANY

THE new German School for the Study of Tropical Diseases is to be established at Hamburg Professor Koch to whose initiation the school is due, designed at first to locate the school in Berlin, but the great port of Hamburg has been wisely substituted so that a patient can be transferred directly from the ship to the hospital bed Accommodation is being provided for 30 patients

THE OPEN-AIR TREATMENT OF CONSUMPTION

IT is, perhaps, not sufficiently well known to the profession that it is to the initiative of the late Dr George Bodington of Sutton Coldfield, near Birmingham, that we owe the introduction of the open air treatment of consumption In 1840 he published a small book entitled, "The Treatment and Cure of Pulmonary Consumption" For some years he had been treating consumptive patients upon the open air and over feeding system and this book was the outcome of his researches and experience He protested most earnestly against the then prevailing plan of carefully confining such patients from fear of the evil influence of cold fresh air and so "forcing them to breathe over and over again the same foul air contaminated with the diseased effluvia of their own persons" He opposed vigorously the prevalent lowering treatment by antimony, calomel, and bleeding, and urged the administration of plenty of good solid food combined with exercise in pure air He advocated "frosty" air if possible and preferred the dry air of inland districts to that of the seaside His great specific was cold, dry air which he considered had a most powerful influence in "healing and closing the cavities and ulcers of the lungs" It is certainly remarkable, as we have already pointed out, "that a village doctor should have arrived in 1840 at these conclusions which anticipated some of our most recent teachings" As might have been expected such novel teaching met with the bitterest and most violent opposition and this openly expressed dissent and disapproval by the profession had the natural result of making patients averse to undergo the treatment, with the result that Dr Bodington was not able to pursue his investigations But he had sowed the good seed which henceforth began to spring up and propagate, he had lighted a lamp which has never since been put out Only six years after this book appeared Dr John Hughes Bennett, who must have been well aware of Dr Bodington's work and the great controversy it raised, became a convert to his views Writing in 1871 in "Reynolds's System of Medicine," Vol III, page 578, he says "It is now 25 years since I became convinced of the injury of shutting up patients in their rooms during winter and regulating the temperature as was formerly the custom" Some years after Dr Hughes Bennett's conversion to open air treatment, we find a far greater publicity being given to Dr Bodington's views by a very favourable though tardy review of his book by Dr Benjamin Ward Richardson in 1857 in the January number of the

Sensitive putrefactive gases, although on opening the coffin some months afterwards very little remained of the body if the rabbit except fur and bone

DISINFECTING THE AIR OF THE HOUSE OF COMMONS

WE announced a short while ago that it was proposed to try the effect of ozonizing the air of the House of Commons,

since apparently the idea gained ground that the air of the House was the source of the epidemics of influenza which prevailed annually and markedly amongst the members. In spite of the statement of Mr. A. K. Douglas that the experiment could not be entertained on the score chiefly of expense, while there was no certainty of the practical merits of the process, we believe on very good authority that some steps are being undertaken for ozonizing the air on an experimental scale. In the meantime a correspondent has suggested that for this purpose nitric peroxide would serve as an excellent gaseous disinfectant. The gas is cheap and easily obtained. Moreover, it acts as a carrier of oxygen, for as soon as it has done its work of disinfection and reduction of nitric oxide may be made to take up oxygen again by simply allowing it to come into contact with the air. This is very ingenious, but we fear that the method would be far too drastic for the purpose. Nitric peroxide in contact with moist air has a tendency to form nitric acid and its use in the House of Commons might prove the remedy to be worse than the disease. The effect of nitric acid upon the ornaments (and especially metal) parts of the chamber may be imagined. For other purposes the proposal may be valuable. Thus our correspondent records an experiment in which a very offensive public latrine was purged and made clean. In another experiment the results distinctly showed a purifying effect upon the air. It is conceivable that with special precautions the method could be applied to the air of public buildings with some advantage.

IN his letter to the press on behalf of the Metropolitan Hospital Sunday Fund and the Lord Mayor refers to a matter to which attention has been called at meetings of the Metropolitan Hospital Sunday Fund—namely, the loss to charity by reason of many of the old and wealthy firms being turned in to limited liability companies which have no power to contribute from their corporate incomes to purposes of charity. It is, of course, no part of the duty of the directors of such companies to propose that any part of the dividends should be set aside for charitable purposes, but it is possible, and even probable, that if the Lord Mayor were to address a letter to such companies asking for subscriptions to the Fund the matter would be discussed at the meetings and a donation granted.

Mrs W. M. HARRISON, C.I.E., was the guest of the Lancers at a dinner held on Monday last at the L. James's Restaurant under the chairmanship of Mr. Fielden, F.R.S. Lord Lisser who was present gave a brief and clear explanation of Mr. Haffkine's methods of prophylactic inoculation against cholera and concluded his remarks with an eloquent expression of contempt for the unworthy persons who begrudge all sorts of success to members of the Jewish race.

At Grosvenor House on Wednesday next the Duke of Westminster will present the Rev. Canon Fleming, B.D. with a testimonial which has been subscribed for by many of the well known clergyman's friends and admirers. We are glad to learn of the recognition of Canon Fleming's splendid work and all who have the welfare of the sick at heart.

ANNUAL REPORT OF THE SCOTISH LOCAL GOVERNMENT BOARD

THE fourth annual report of the Local Government Board for Scotland has been issued. It is divided into six parts—Poor law, Audit, Local Government Public Health, Vaccination, and Departmental. Under the first heading a summary is given of Sheriff Campbell's report on the conduct of officials in an outbreak of typhoid fever in South Fife. It is in this outbreak that the then medical officer, Mr. Lamont (whose personification with regard to another matter has recently been so well exposed in the House of Commons by Sir Charles Cameron), figures not only prominently but heroically. "He got no instructions, information, or guidance from the parish council or inspectors as to the health or condition of the people or patients. He was on duty practically night and day, in frequent storms and rains over moors and across dangerous fords all over the parish, from the island of Birsay in the south to the island of Benbecula in the north—38 miles apart. Notwithstanding this he paid six visits to the deceased Mary Holmes during the 12 days she lived after his first visit. He ministered to her professionally and in many mental services without aid and on her death he also practically unaided, prepared her body for interment under extraordinary and exceptional difficulties." Mr. Lamont well deserves the "high appreciation of his conduct" formally recorded by the Local Government Board for Scotland.

In the vaccination returns a very striking fact is the remarkably small part which public vaccination (in the sense of the Scottish Vaccination Act) plays in Scotland. The total number of persons operated on by the official vaccinators in the year ending June 30th, 1898 was only 2173 in the whole country. In the half year January to June, 1898, there were eight counties—some of them, it is true, very small counties—without a single official vaccination. It is not to be understood, however, that all the rest of the nation in Scotland are done by medical men in their capacity of private practitioners. In the large towns there are

THE second annual conversation of the Royal Society (Ladies night) will be held on Wednesday evening, June 21st, at Burlington House.

H.R.H. THE DUCHESS OF YORK will open the new Nurses' Home of Queen Charlotte's Hospital in the Marylebone road on July 17th.

CHOLERA in a severe form has broken out in Buxarache. The mortality has reached alarming figures, over 200 deaths per diem occurring during the week.

WE desire to draw attention to an advertisement now appearing in our columns (p. 91) headed, "To the Benevolent." The case is a thoroughly deserving one.

SIR WILLIAM MACCOWAN has been elected an Honorary President of the Thirteenth International Congress of Medicine to be held in Paris from August 2nd to August 9th, 1900.

THE DUCHESS OF YORK will open the new building of the Royal London Ophthalmic Hospital in City road on Tuesday afternoon, June 27th, and not on June 26th, as previously arranged.

WE regret to announce the death at the early age of fifty-four years of Mr. Lawson Tait. He had not been in good health for some months, but the end was sudden and unexpected. We shall publish an obituary notice in an early issue.

REMEMBERING his efforts in behalf of the Metropolitan Hospital Sunday Fund, will share our feeling

hospital. It is not only in "ways" that are dark and tricks that are vain" that the heathen Chinese is peculiar, but also in his methods of medicine. He possesses the notion that the devils of disease can be frightened away in the same way that young Hodge in England frightens away birds from the growing corn, hence the application to cure the plague by a wild procession through the infected quarter with shrieks and yells and a noise suggestive of an unloosed pandemonium. According to the *China Mail* of May 9th the plague is more than recrudescing in many of the towns and villages of the delta. In Canton and Fatshan it is reported as "bad" but not so bad as in some of the inland cities. The city of San Ning might correctly be named at present "the city of death." The plague is raging with special virulence and carrying off its victims in large numbers. Shops and dwelling houses are closed and their inhabitants have fled into the country. Business is for the present paralysed. The streets, meanwhile, are reeking in filth and all drains are choked with rubbish. In one street, no less than three mat sheds were erected, in which were seated in calm complacency many idols, which are implored to exert their power to stem and turn back the tide of death. Almost every door is hung with branches of cactus or other thorny shrubs, a piece of fine netting, and a bag of small cockle-shells. It is believed that the malignant devils cannot well avoid all these obstacles and enter the house. If the devils yet attempt to enter they must pass through the mass of thorns but can scarcely avoid the small netting.

THE DEVELOPMENT OF THE MOTOR CAR

THE fête held this week in the Tuileries Gardens at Paris appears to have been highly successful from the point of view of its promoters, and the flower decked cars combined with fine weather no doubt attracted a large concourse of sightseers. France is admittedly ahead of us in the building of these vehicles and we note that a prominent feature of the fête was supplied by an electric car owned by M. Tenetzy, which is cigar or torpedo shaped and is said to travel on a good road at any pace up to 65 miles an hour. Even with the customary grain of salt necessary for the appreciation of novelties in our neighbours' locomotion, aerial, terrestrial, or submarine, 65 miles an hour is good going and most of us would be happier at a less startling pace. We fail, however, to see that any substantial progress has been made towards perfecting a motor car of practical utility to the work-a-day man, who may perchance take a loving pride in his horse and trap, but to whom a higher rate of speed, or the same measure of usefulness at a less cost, would turn the scale in favour of the motor car. Of all the professions the medical profession was the one from which inventors of horseless carriages might well expect support; provided they could furnish them with what they needed. It had to combine speed, simplicity, and cheapness, with moderate comfort in travelling. Electricity, speedy and clean as it is, was and is still practically out of the question in most districts. The provision of charging stations and the weight of accumulators for country by-roads in wet weather, besides the jar of a heavy vehicle moving rapidly over an uneven surface, were obstacles not to be easily overcome. If all oil motors do not smell abominably we certainly meet many that do, while if their unsightliness is a matter of taste the weight of some of them is only too apparent, but at the same time their fuel is everywhere obtainable should the supply carried run short on an unexpectedly prolonged journey. Meanwhile, all roads are not main roads, and those who travel for business and not for pleasure cannot always choose their way or their weather. Motor cars can never be a fashionable craze with a horse loving people, and their practical usefulness, except

perhaps as weight carriers on roads ascertained to be suitable, has yet to be demonstrated by a vehicle which has not, so far as we know, at present appeared.

THE TEACHING OF PATHOLOGY AT OXFORD

FOR a long time the accommodation placed at the disposal of the teacher of pathology at the Oxford University has been inadequate to meet the requirements of the students attending the courses. From time to time the University has been urged, first by Sir Henry Acland and more recently by Sir John Burdon Sanderson, to provide suitable laboratories, but the impoverished condition of the University chest has been such that although these proposals were sympathetically received the funds were not forthcoming. Recently, however, the matter has been taken up with renewed energy owing to the kindness of an anonymous donor who has promised a sum of £5000 provided that within a certain date the University carries out the plan of the suggested laboratories. Such a scheme entails the expenditure of £10,000 on buildings and the first stage was reached last Tuesday when Congregation passed a grant of £5,000 to supplement the sum already subscribed by the anonymous donor. The circumstances of the vote were particularly pleasing, for whereas it was announced that opposition from various sources would be raised, the house, which was well attended, passed the decree without any discussion whatever. At the same time an annual grant of £250 for upkeep and maintenance was passed without opposition. In view of the friendly attitude of the University it is most probable that these decrees will be presented to Convocation during this term, and in all likelihood, if no opposition be encountered, building operations will be started in the long vacation. In little over a year's time Oxford will be provided with a pathological department second to none in regard to convenience of arrangement and fittings. Already a further fund for the purchase of apparatus is being generously contributed to, so that in this respect also the laboratory will be well equipped.

SEWER VENTILATORS

SEWER ventilators are an abomination but a necessity of the modern system of sanitation, so that any proposal to reduce the nuisance without interfering with the proper function of the ventilators will be welcomed. Sir Charles Camm has suggested employing porous cylinders as a kind of lid placed in the crown of the sewer. As is well known, plaster of Paris or unglazed porcelain is sufficiently porous to allow of the escape of gas through the material. While these cylinders therefore would allow air to pass freely through them they would effectually bar the passage of micro organisms and at the same time there would be no greater pressure in the sewer air than in the street atmosphere. Indeed, the action is twofold, diffusion and filtration simultaneously taking place. Air thus continuously comes out of the sewer filtered through the cylinders, and on well known principles of diffusion air as continuously enters the sewer through the porous vessel. It is stated that this method has given satisfaction in Dublin and has proved effective, having been in use for the last two years, the porous ventilators being quite clean at the end of that time. It is possible also that some amount of deodorisation is effected since the oxygen and putrefactive gases in passing through a porous material are brought into very intimate contact and the gaseous organic matters are thus oxidised. We have had some evidence on this point in some experiments with coffins made of porous ware. When the body of a dead rabbit was placed in a porous coffin and the latter was sealed with plaster of Paris there was hardly any evidence of the evolution of

What perhaps interested him most was the large number of general practitioners of all ages whom he saw present. He reminded members of the Legislature that the work which was proposed to be done was of no ordinary kind and was not taken up for the benefit of any individual or number of individuals. The work had been taken up by reason of the fact that a large number of persons in the medical profession needed a certain amount of help owing to the great progress made by medicine in these days. Medical education—long protracted as it now is—did not give a man a few years the country practitioner felt himself to be behindhand. It would be the object of the College to enable such men to acquire in the easiest way new knowledge and technical skill.

The Hon ALFRED LYTTELTON, M.P., in an amusing speech responded for the two Houses.

Sir JOHN LUBBOCK, in proposing "The Medical Graduates' College and Lyceum," said that as a general rule when it was proposed to found a new institution the object was to give a stimulus to some languishing cause or because existing institutions had failed in their duties. Neither of these reasons applied in the present case.

The existing colleges and hospitals were admirably and efficiently fulfilling the dearest duties for which they were constituted and it was their very success and the marvellous progress of medical science which had led to the formation of the Polytechnic College. As evidence of progress he mentioned the invention of complex and ingenious instruments such as the stethoscope, the ophthalmoscope, the laryngoscope, the cardiograph, the sphygmograph, the pneumograph, and others.

There were also the applications to medicine of other physical appliances and discoveries, such as the clinical thermometer, the microscope, and the Roentgen rays, the discovery of many new and important drugs, the use of anaesthetics and the antiseptic treatment, the new modes of treatment, the operations which were formerly impossible, especially in brain and abdominal surgery. There was also the discovery of new branches of science, such as anatomy, physiology, pathology and bacteriology. The mere mention of these things, he knew, very imperfectly showed the marvellous progress of medical science during the last half century.

Though the course of study had been prolonged from four to five years no student however diligent or able could hope to master in the time so vast a range of subjects. But even if that were possible science was still advancing, new discoveries were being made new methods and new inventions were being devised, and in a few years the student would find himself left behind. The aim of the Polytechnic College would be to facilitate the life-long education of medical men in all directions and to give them the opportunity of making themselves acquainted with all fresh discoveries. It would contain a collection of instruments and appliances and a first-rate library. Special lectures would also be given within its walls. All this could be effected in one central and special institution which would not come in conflict or competition with the various medical schools but in which it was hoped would work in close association with them.

The arrangements of modern life and the rapidity of communication had made schemes now possible which would formerly have been out of the question. Medical men resident in the country in all parts of England could easily make short visits to London and avail themselves of the opportunities which the College would afford. It was hoped also that some would come from abroad and from our colonies. It was also proposed to organize a certain number of daily consultations. These would be open to all medical men who had joined the College, and they were designed for the double purpose of giving advice to patients and at the same time of affording medical men opportunities of becoming practically familiar with exceptional forms of disease and with the best and most modern methods of diagnosis. It was proposed to provide hospital accommodation or to undertake continuous treatment. In this matter the Polytechnic would act in concert and consultation with the hospitals and with private practitioners. It would not compete with hospitals but to some extent supply them and assist their work. The institution had been practically founded by Mr Hutchinson who was generously going to deposit in its museum his unique collection of clinical material and a splendid collection of books, and he

was devoting to it much of his invaluable time. It certainly seemed to him (the speaker) that this institution had been admirably devised and would be most useful. His opinion, however, was worth little, but their opinion was worth much and they had shown it to be the same by their presence that evening. With the toast he coupled the names of Sir William Broadbent and Mr Hutchinson.

Sir WILLIAM BROADBENT, in his reply, said Sir John Lubbock had rated his judgment on the work of the medical profession as not of any practical value, as a matter of fact, however, the medical profession appreciated his judgment and the commendation which he had given to their work very highly and they could have no better judge of the value of the institution which he had proposed. The number of medical men present was a sufficient answer to the question, "Is this association likely to be of use?" and was a sufficient demonstration of the interest which it excited. Whenever he went he heard of the value which general practitioners attached to the association, and it was most interesting to notice the zeal of the general practitioner for medical knowledge and his desire to keep up in every respect with the advances of medical science.

Mr HUTCHINSON, in the course of a long and interesting speech, spoke warmly as to the benefits which would accrue to the community from the Polytechnic. He said that Dr Ord, the chairman, and Sir William Broadbent had described the advantages of the institution to medical men and he would like to point out that this institution much concerned the public. It was greatly in the interests of the public that the profession should be well educated and it was a medical practitioner was willing to spare the time to keep himself abreast with the advance of knowledge the public ought to support him.

Sir JOSEPH FARRER, Bart., in proposing "The Medical Schools," looked forward to the time when the students at the medical schools of London would be considered as much as undergraduates as if they belonged to the ancient universities and would eventually become graduates of the University of London.

Dr STEPHEN MACKENZIE replied and other toasts were given. In the course of the evening an enjoyable evening. The course of the proceedings subscriptions amounting to 4000 guineas were announced, including £1000 from Mr Hutchinson.

ROYAL ARMY MEDICAL CORPS DINNER.

THE annual dinner of the Royal Army Medical Corps took place at the Whitehall Rooms, Hotel Metropole, on June 12th, Surgeon General J JAMESON, C.B., the Director-General, being in the chair. There was a large attendance of officers and the evening proved a very pleasant and successful one. After the toast of "The Queen" the Chairman gave "The Health of the Chairman" and alluded to the great services which the Director-General had rendered in connection with the reforms which had enabled them to become a Royal corps with army rank—placed them in connection with the reforms which had rendered them the result of his labours. The following is a list of names of officers present: Surgeon General J JAMESON, C.B. (Director-General), A. A. Gore, O.B., R. Harvey, O.B., D.S.O., H.S. Malt, W. Nash, T.E. O'Dwyer, A. R. Preston, J. B. O. Reade, W. R. O.B., R. B. Smith, and W. D. Wilson. Colonels: W. G. Burnett, J. A. O'Leary, O. Codrington, H. Comford, W. G. Don, A. W. Duke, J. J. Galloway, O.B., C. A. Innes, T. Lightwood, J. T. Notter, J. O'Farrell, and W. F. Stevenson. Lieutenant-Colonels: W. H. Allen, W. B. Allen, J. F. Beattie, G. D. Bourke, U. J. Bourke, A. L. Browne, W. T. Chester, A. E. S. Clarke, W. Donovan, J. D. Edge, R. Egan, J. A. Gormley, W. I. Gabbins, W. Hector, R. D. Hodgson, J. R. Hunt, W. Johnston, W. Kear, W. W. Kenny, H. O. Kirkpatrick, B. W. S. Large, H. Mackinnon, D.S.O., W. A. May, W. Rainford, W. R.

The result of the dinner, is to be congratulated on the result of his labours. The following is a list of names of officers present: Surgeon General J JAMESON, C.B. (Director-General), A. A. Gore, O.B., R. Harvey, O.B., D.S.O., H.S. Malt, W. Nash, T.E. O'Dwyer, A. R. Preston, J. B. O. Reade, W. R. O.B., R. B. Smith, and W. D. Wilson. Colonels: W. G. Burnett, J. A. O'Leary, O. Codrington, H. Comford, W. G. Don, A. W. Duke, J. J. Galloway, O.B., C. A. Innes, T. Lightwood, J. T. Notter, J. O'Farrell, and W. F. Stevenson. Lieutenant-Colonels: W. H. Allen, W. B. Allen, J. F. Beattie, G. D. Bourke, U. J. Bourke, A. L. Browne, W. T. Chester, A. E. S. Clarke, W. Donovan, J. D. Edge, R. Egan, J. A. Gormley, W. I. Gabbins, W. Hector, R. D. Hodgson, J. R. Hunt, W. Johnston, W. Kear, W. W. Kenny, H. O. Kirkpatrick, B. W. S. Large, H. Mackinnon, D.S.O., W. A. May, W. Rainford, W. R.

public stations for gratuitous vaccination in connexion with hospitals and medical schools, &c., but these are not maintained under the Vaccination Act. It is a little inconvenient to have to go to other official reports for the statistics of these public stations and of vaccination default in Scotland. Could not all the facts be published in the one document? From a short report by Dr. William Husband, superintendent of the Central Vaccine Institution for Scotland, it appears that 2591 tubes of humanised lymph were distributed to 423 practitioners and that six applications for calf lymph were received and acceded to. As to calf lymph Dr. Husband adds: "It is satisfactory to know that the English Local Government Board have intimated their intention, when the necessary arrangements are completed, of furnishing us with a limited supply for distribution in Scotland."

In public health the Board has evidently had a busy year consequent on the coming into operation of the Public Health (Scotland) Act, 1897. It has issued circulars and model by laws and cholera regulations, &c., and has given advice to local authorities on many legal points. On a much disputed question as to whether under Section 57 of the Scottish Public Health Act the medical officer of health is bound when called on to certify as to the freedom from infection of children who have recovered from infectious disease the Board indicates incidentally the reasonable opinion that it is only where he is "acquainted with the facts of the case" that a certificate can be expected from him. On the question of the respective obligations of sanitary authorities and parish councils regarding pauper cases of infectious disease the Board says: "In our opinion the parish council is bound to treat cases of infectious disease occurring among paupers or proper objects of parochial relief. The Public Health Act does not relieve them of that obligation and their liability continues. But when a local authority, acting under the Public Health Act and for the protection of the public health, remove or isolate the patient all the expenses necessarily incurred for this purpose form a charge against the public health assessment and cannot be recovered from any other person or body." Under Section 65 of the recent Act by laws may be framed for securing the cleanliness and sanitary condition of public conveyances *plying within the district* of the local authority, and for preventing overcrowding in such conveyances. Among the by laws under this section submitted to the Board for confirmation were two applicable to railway carriages. The law officers of the Crown advised the Board that railway carriages were not included in "public conveyances" under the Act, "but the local authority after reconsideration submitted new by laws which applied to public conveyances generally without distinction, thus leaving open the question of their applicability to railway carriages." By Section 39 of the new Act, sanitary authorities can compel owners of private streets within special scavenging districts to level and pave such streets, and the Board's report gives very useful guidance as to the administration of this most important section. With regard to hospitals the report says: "The fact that we are now armed with compulsory powers under Section 44 of the Act has enabled us to give an impetus to hospital provision. Wherever we found that a medical officer of health in his annual report had been urging hospital accommodation for his district we gave the matter special attention and where we thought it advisable seconded the efforts of the medical officers, reminding the local authority of our powers under the aforesaid section." On the subject of the employment of nurses for attending persons suffering from infectious diseases in their own homes the Board points out that only its general sanction is required, because to require consent in each case would often frustrate the object in view—the immediate and thorough isolation of the patient. It also indicates that the employment of such nurses is not to be regarded as a substitute for the provision of hospitals. In one or two sparsely populated Highland districts a one year's experiment is, however, being made of the employment of nurses and the medical officer of health is to report to the Board at the end of the year, so that if the result be satisfactory they may be prepared to consider further schemes on a larger basis, as they think that "within reasonable limits the larger the number of local authorities which combine for fever nursing the less will be the difficulty in meeting demands which may suddenly arise." With regard to an outbreak of typhus fever in Skye the local medical officer, Dr. Dewar, "reports that even at mid day there was so little light that he was obliged to find the

patients by means of match light. The small fired windows were grimy with dirt and smoke. For six weeks before his visit the whole family of six had been living solely on mashed potatoes and tea, partaken of three times a day. Comparing this outbreak with previous outbreaks he found the condition and surroundings practically identical. These were—overcrowding, want of ventilation, filth, and poverty." Only 28 cases of small pox were notified in Scotland during 1898. The following table shows the prevalence and fatality of notified infectious disease in an aggregate population of 3,763,579 being that of 228 local authorities which had adopted the Notification Act in 1897—

Diseases Specified in the Act

	Cases notified.	Deaths.	Percentage of deaths to notifications in 1897
Small pox.. ..	80	8	10.0
Cholera	1	—	—
Diphtheria	2,532	505	19.9
Membranous croup ..	185	76	41.1
Erysipelas	4,014	128	3.2
Scarlet fever	19,716	631	3.2
Typhus fever	169	28	17.6
Enteric fever	3,911	614	15.7
Relapsing fever	9	—	—
Continued fever	113	7	6.2
Puerperal fever	228	108	47.4
Total	30,948	2105	6.8

Diseases to which the Act has been Extended

Measles	15,058	433	2.9
Whooping-cough	534	107	20.0
Choleraic diarrhoea ..	3	—	—
British cholera	—	—	—
Total	15,595	540	3.5
Grand total of both classes ..	46,543	2645	5.7

A table of the salaries of medical officers of health in Scotland contains some curious figures. 16 burghs appear to have no medical officers of health but these are no doubt only temporary vacancies. In four burghs the salary is £1 per annum, in two it is £1 1s., in one it is 25s., in another it is 30s., and in 17 it is £2 or £2 2s. It may be assumed that these are very small burghs but they are surely not so very microscopic as to justify the payment of such ridiculous pittance to their health officers.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC

NEARLY 300 gentlemen representing all grades of the medical profession assembled under the presidency of Sir JOHN LUBBOCK, Bart, M.P., at the Trocadéro Restaurant on Wednesday evening last, the occasion being the inaugural dinner of the Medical Graduates' College and Polyclinic.

The toast of "The Queen" and also that of "The Prince and Princess of Wales and other Members of the Royal Family" having been honoured Dr. W. MILLER ORD proposed "The Houses of Parliament." He regretted the unavoidable absence of Lord Lister who had written a letter to Mr. Hutchinson expressing his cordial approval of and hopes of prosperity for the College, and remarked on the number of men whom he saw before him representing the profession in varied interests and paths. He saw before him distinguished representatives of the medical services, the navy, and the army, and scientific men engaged in one kind of medical research which advanced science in one way and helped the medical man in another, and together helped greatly the advancement of legislation for the

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Urban District—Dr. E. W. Hope's annual report just published is a comprehensive volume of more than 200 pages. It is illustrated by maps, diagrams, and photographs and contains the results of analyses and inspections. The report comprises a preface and a summary of the main features of the volume and is of great value in referring readers for detailed information on specific points. The estimated population of Liverpool is 668,641, and the total number of deaths at all ages and from all causes during the year 1898 was 15,380 which represents an annual rate of mortality equal to 23 per 1000 of the inhabitants. The total deaths, however, were not all deaths of residents in the city. Liverpool is a large medical centre and is well provided with hospitals, dispensaries, and other medical charities which attract patients from a very wide surrounding area and in any one of these institutions is included amongst the deaths of every stranger to the city which occurs in any one of these institutions is included amongst the deaths of citizens and increases the apparent rate of mortality in the city. When these have been verified and deducted the annual rate of mortality is reduced to 22.2 per 1000. This death rate is the lowest with one single exception (1898) which has ever been recorded in the city of Liverpool and represents a reduction of 1 per 1000 below the average of the four years since the extension of the city boundaries. The reduction in the rate of mortality shows itself in each of the 11 districts of the city, with the exception of Walton, which was exceedingly low in 1897 and stood at precisely the same figure in 1898. It will be seen that while there was a reduction in the death rate it is only from certain causes that the number of deaths had undergone any conspicuous diminution, these causes being due to the efforts of the group of typhoid diseases, in which the steady decline of previous years has been more than maintained. The most marked decline was in those forms of typhoid disease which it has been possible to treat and to isolate in hospitals. Scarlet fever may be instanced as showing how ready, and to what an increasing extent the quibbling have called themselves of this accommodation as to what is really, and to what an increasing extent the accommodation is provided and which are usually regarded as the less serious forms (such as measles, whooping-cough, and diphtheria) the diminution is relatively inconspicuous. The remarkable diminution in deaths from various forms of infectious diseases is not less conspicuous than the foregoing. One of the most remarkable as well as the gratifying features in regard to this disease is the great diminution in the rate of mortality in the very early years of life from the forms of tuberculosis peculiar to those ages. This diminution does not appear to have been ascribed in the thorough county generally. Small pox and typhus have become comparatively rare. In the section of the report dealing with sanitary administration it will be seen that various additions have been made to the medical officer of health's staff. The rule which requires candidates for serious occupations to be vaccinated has been strictly adhered to and will be called upon for the duties which the will be called upon to perform. It is not only important that the contract has been made by the council and is in force.

the consideration which had led the Liverpool City Council to give its support to the school of hygiene in University College where full and complete preliminary training can be obtained by those who desire to become inspectors in any branch of the medical officer's staff. With regard to matters affecting house sanitation the number of applications for assistance made by the public increases every year, they relate in the main to jerry built property or old and worn out insanitary property. Systematic house-to-house visitation was carried out by the district staff, both male and female, and special attention was given to the miserable class of property known as courts and alleys. Interchange of information between the medical department and the other departments had considerably increased, except in the case of the references to the School Board, which, owing to the diminution in infectious cases, fell from 15,000 to 11,000. With regard to the female sanitary staff it is worth noting that there was a very large increase in the number of families visited and a considerable diminution in the proportion reported as dirty. Ignorance of the language interposed a serious barrier to the efforts to improve the condition of the foreign Jews, chiefly Polish and Russian, important and responsible duties were carried out by the ambulance and disinfecting staff, no less than 2387 patients were removed to hospitals, and the consequent disinfection of houses, bedding, clothing, &c., had been attended with very satisfactory results. The cleansing of infected premises under a £300 rental was also undertaken by men connected with that branch of the staff. Under the Food and Drugs Act a great variety of samples had been taken for chemical and bacteriological analysis. The various brands of wheats known as condensed milk had been completely examined and a considerable variety had been found in their composition. As in preceding years, considerable attention had been paid to the sources of the milk supply. In comparing the number of samples of town milk with the number of samples of country milk found to be contaminated with tubercle it must be remembered that the town samples were chiefly taken from suspected sources, whereas the country samples were taken as they came without selection. The surveillance that is now maintained over shops within the city had produced excellent results. Dr. Hope reports that 11,000 gallons of milk were brought into Liverpool every day from the country and about 12,000 gallons more were provided within the town shops. Analyses showed that the town milk was purer and the town cows more healthy than was the case in the country, facts due to the better sanitary conditions which had been brought about by the inspection of shops within the city. The demolition of insanitary property had proceeded gradually, the number of courts and alleys as at present 1666, as against 1660 in 1895. There is a very large amount of property which is so constructed as to be destructive to the health and the life of those living in it—pent-up, and it is not surprising that the general rate of mortality in it from year to year and rising to 60 per 1000. The deaths were chiefly amongst the infants, but the general condition of the inhabitants was in every way improvable. Considerable benefit had attended the improvements in the system of cleansing and scavenging, the increased use of water, for street washing had resulted in a conspicuous good, and the inverse ratio between the annual diarrhoeas and the rainfall or water used in street washing is very remarkable. But progress had been made during the year towards the provision of adequate hospital accommodation for persons suffering from infectious diseases. The present number of beds available for the various forms of infectious sickness is as follows: City Hospital, 147 beds, Parkhill Hospital, 166 beds, and Priory Hospital, 42 beds, making a total of 455 beds. They are approximately 37 beds, small pox, 37 beds, typhus fever, 20 beds; typhoid fever, 75 beds, scarlet fever, 288 beds, and diphtheria, 100 of these beds are located in buildings of a temporary character which are practically worn out and at no distant date will require to be taken down. At the lowest computation, and upon a wide experience, and embodied in the recommendations of the Local Government Board, Liverpool requires a minimum of 650 beds for ordinary infectious diseases and 100 beds for special infectious diseases. The close of the year 1898 was a most successful one for the medical officers of health, and it is not only important that the contract has been made by the council and is in force.

Ruttledge, M R Ryan, P B. Tuthill, O G Wood, and T W Wright *Majors* W Babbie, O M G, M W Baker, W G A Bedford, M O D Braddell, O H Burtchaell, A M Davies, J D Day, A Dodd, S F Freyer, H Grier, F A Harris, E M Hassard, H Hathaway, J Hickman, S Hickson, G Hilliard, C M G, H E R James, R Jennings, O R A Julian, R E Kelly, A Keogh, S F Loughheed, H J McLaughlin, W J Macnamara, W G Macpherson, H J Moberly, J D Moir, A H Morgan, F J Morgan, E North, D M O'Callaghan, T J O'Donnell, E V A Phipps, W Pope, M W Russell, A A Sutton, G T H Thomas, F H Treherne, G T Trewman, S Westcott, and E M Wilson, O M G, D S O *Captains* K B Barnett, T B Beach, H J M Buist, H E Dowse, H G Faichne, M L Hughes, J O Jameson, S G Moores, E M Polcher, O W Profit, P H Whiston, L Way, and E. McK Williams. *Guests* Mr Vesey Holt, Mr Thomas Wakley, jun., and Dr Dawson Williams. The Director-General of the Medical Department of the Royal Navy and the President of the Indian Medical Board were also invited but were unable to be present

INDIAN MEDICAL SERVICE DINNER

THE annual dinner of the officers of the Indian Medical Service was held at the Hotel Cecil on June 8th, Surgeon-General Sir W GUYER HUNTER, K C M G, being in the chair. The occasion is always a pleasant one and this year its reputation was fully maintained. At the conclusion of an excellent dinner and after the usual loyal toasts had been honoured "The Navy and Army" was proposed by Dr W S PLAYFAIR and responded to by Sir HENRY F NORBURY, K O B, Director General of the Royal Navy Medical Service, and Surgeon General J JAMESON, C B, Director General of the Army Medical Service. The health of "The Guests" was given by Surgeon General Sir JOSEPH FAYRER, Bart, K O S I, and acknowledged by Mr BRYANT, President of the Royal Medical and Chirurgical Society. "The Indian Medical Service" was proposed by Mr EDMUND OWEN, late President of the Medical Society of London, and responded to by the CHAIRMAN and Surgeon General HARVEY C B, D S O Director General of the Indian Medical Service. The CHAIRMAN expressed the thanks of the meeting to Surgeon Lieutenant-Colonel P J Freyer for his successful efforts as honorary secretary of the dinner, and that gentleman suitably responded. The various speeches were interesting and to the point.

The following is a list of the names of the officers who were present—*Surgeon Generals* Sir W Guyer Hunter, K C M G (chairman), Sir Joseph Fayrer, Bart, K C S I, F R S, R Harvey, C B, D S O (Director General I M S); A. C C De Renzy, C B, W R Rice, C S I, and P W Sutherland. Dr W S Playfair and Dr H W G Macleod (retired officers I M S). *Colonels* A M Branfoot, W E Cates, H Cayley, C P Costello, D A Hughes, J O Penny, A Porter, W H Roberts, B Williamson, and W A S Wynne. *Lieutenant-Colonels* H Armstrong, Oswald Baker, W Cadge, J W Clarkson, A Crombie, A Dane, E J Drake Brockman, Theodore Duka, G A Emerson, P J Freyer, J O Fullerton, G Grant, D J Keegan, J B Lyon, C I E, J Maitland, G. Massy, H K McKay, J Parker, J Reid, G D Riddell, J B Scriven, J G Skardon, G S Sutherland, W H Thornhill, and A H Williamson. *Majors* W S Caldwell, F Carter, G N P Dennys, A S Faulkner, O Gilbert, S Hassan, P Hehir, H Herbert, R S Lyons, P D Pank, F Peck, F G Reeves, J Scott, H W Stevenson, J N Tuohy, and D P Warliker. *Captains* J T Calvert, K H Caster, H E Drake-Brockman, G Ramsey, R F Standage, R. G Turner, and C J R Whitcombe. *Lieutenant* J N Smith.

METROPOLITAN HOSPITAL SUNDAY FUND

THE following is a record of some of the principal amounts received at the Mansion House, according to the lists which have reached THE LANCET Office up to the time of going to press on Thursday, when the total sum amounted to over £22,000. At the corresponding period last year the total was £14,000.

Rutledge, M R Ryan, P B Tuthill, O G Wood, and T W Wright *Majors* W Babbie, O M G, M W Baker, W G A Bedford, M O D Braddell, O H Burtchall, A M Davies, J D Day, A Dodd, S F Freyer, H Grier, F A Harris, E M Hassard, H Hathaway, J Hlozman, S Hickson, G Hilliard, O M G, H E R James, R Jennings, O R A Julian, R E Kelly, A Keogh, S F Longhead, H J McLaughlin, W J Macnamara, W G Macpherson, H J Moberly, J D Moor, A H Morgan, F J Morgan, E North, D M O'Callaghan, T J O'Donnell, E V A Phipps, W Pope, M W Russell, A A Sutton, G T H Thomas, F H Treherne, G T Trewman, S Westcott, and E M Wilson, O M G, D S O *Captains* K B Barnett, T B Beach, H J M Buist, H E Dowse, H G Fafchne, M L Hughes, J O Jameson, S G Moores, E M Pilcher, O W Profet, P H Whiston, L Way, and E McK Williams *Guests* Mr Vesey Holt, Mr Thomas Wakley, jun., and Dr Dawson Williams The Director-General of the Medical Department of the Royal Navy and the President of the Indian Medical Board were also invited but were unable to be present

INDIAN MEDICAL SERVICE DINNER

THE annual dinner of the officers of the Indian Medical Service was held at the Hotel Cecil on June 8th, Surgeon-General Sir W GUYER HUNTER, K O M G, being in the chair. The occasion is always a pleasant one and this year its reputation was fully maintained. At the conclusion of an excellent dinner and after the usual loyal toasts had been honoured "The Navy and Army" was proposed by Dr W S PLAYFAIR and responded to by Sir HENRY F NORBURY, K O B, Director General of the Royal Navy Medical Service, and Surgeon General J JAMESON, O B, Director General of the Army Medical Service. The health of "The Guests" was given by Surgeon General Sir JOSEPH FAYRE, Bart, K O S I, and acknowledged by Mr BRANT, President of the Royal Medical and Chirurgical Society. "The Indian Medical Service" was proposed by Mr EDMUND OWEN, late President of the Medical Society of London, and responded to by the CHAIRMAN and Surgeon General HARVEY, O B, D S O Director General of the Indian Medical Service. The CHAIRMAN expressed the thanks of the meeting to Surgeon Lieutenant-Colonel P J Freyer for his successful efforts as honorary secretary of the dinner, and that gentleman suitably responded. The various speeches were interesting and to the point.

The following is a list of the names of the officers who were present—*Surgeon Generals* Sir W Guyer Hunter, K O M G (chairman), Sir Joseph Fayrer, Bart, K O S I, F R S, R Harvey, O B, D S O (Director General I M S); A C C De Renzy, O B, W R Rice, O S I, and P W Sutherland. Dr W S Playfair and Dr H W G Macleod (retired officers I M S). *Colonels* A M Branfoot, W E Cates, H Cayley, O P Costello, D A Hughes, J O Penny, A Porter, W H Roberts, B Williamson, and W A S Wynne. *Lieutenant-Colonels* H Armstrong, Oswald Baker, W Cadge, J W Clarkson, A Crombie, A Dane, E J Drake Brockman, Theodore Duka, G A Emerson, P J Freyer, J C Fullerton, G Grant, D F Keegan, J B Lyon, C I E, J Maitland, G Massy, H K McKay, J Parker, J Reid, G D Riddell, J B Scriven, J G Skardon, G S Sutherland, W H Thornhill, and A H Williamson. *Majors* W S Caldwell, J Carter, G N P Dennys, A S Faulkner, C Gilbert, S Hassan, P Hehir, H Herbert, R S Lyons, P D Park, F Peck, I G Reeves, J Scott, H W Stevenson, J F Tuohy, and D P Warbler. *Captains* J T Calvert, K H Caster, H E Drake-Brookman, G Ramsey, R F Standage, R G Turner, and C J R Whitcombe. *Lieutenant* J N Smith.

METROPOLITAN HOSPITAL SUNDAY FUND

THE following is a record of some of the principal amounts received at the Mansion House, according to the lists which have reached THE LANCET Office up to the time of going to press on Thursday, when the total sum amounted to over £22,000. At the corresponding period last year the total was £14,000.

† Including deaths from non-infectious group.

experienced from the inability to find accommodation for the patients seeking admission to the hospitals. Many of those for whom accommodation was sought were without proper lodging and accommodation in their own homes, indeed, some of these homes had actually been condemned as unfit for human habitation. About 12,000 people are at present housed in cellars. The requirements of the Liverpool Improvement Act of 1871 and of the Public Health Act of 1875 are very stringent in relation to cellar dwellings and any person who lets or suffers to be occupied any cellar in contravention of these requirements is liable to a penalty not exceeding £10. Proceedings for the abatement of nuisances caused by the excessive emission of smoke from factory chimneys or from steamers were taken under the Liverpool Sanitary Amendment Act, 1854, Sections 24 and 25, and the Liverpool Improvement Act, 1882, Section 77, with the following results: in the case of manufactories 527 reports, in the case of steamers in the river 305 reports, and in the case of steamers in dock 71 reports, making a total of 903, as against 943 in 1897. The total fines enacted for these offences amounted to £1182 11s. 1d., as against £1138 15s. 3d. in 1897. The large and increasing amount paid in fines for smoke nuisances caused by defective house flues and from low chimneys indicates the necessity for care in preventing them. The birth rate in the city of Liverpool was exceptionally high. During the last 10 years the mean has been 34.4 per 1000, which is considerably in excess of most of the 35 great towns. During the 52 weeks of the year 1898 the returns of the local registrars recorded 22,227 births within the city, making the total birth rate of the city equal to 33.2 per 1000 of the population. Of the total births 11,337 were males and 10,890 were females.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6627 births and 3591 deaths were registered during the week ending June 10th. The annual rate of mortality in these towns which had been 16.0 and 17.7 per 1000 in the two preceding weeks declined again last week to 16.4. In London the rate was 15.7 per 1000, while it averaged 16.9 in the 32 provincial towns. The lowest rates in these towns were 10.8 in West Ham, 11.0 in Norwich, 11.4 in Croydon, and 13.2 in Gateshead, the highest rates were 20.8 in Oldham and in Sunderland, 20.9 in Liverpool, 21.0 in Salford, and 22.9 in Manchester. The 3591 deaths included 397 which were referred to the principal zymotic diseases, against 358 and 386 in the two preceding weeks, of these 162 resulted from measles, 79 from whooping cough, 62 from diphtheria, 42 from diarrhoea, 27 from "fever" (principally enteric), 23 from scarlet fever, and two from small pox. No death from any of these diseases was recorded last week in Norwich, in the other towns they caused the lowest death rates in Croydon, Derby, Halifax, and Gateshead, and the highest rates in Swansea, Bolton, Manchester, and Salford. The greatest mortality from measles occurred in London, Nottingham, Bolton, Liverpool, Manchester, and Salford, and from whooping cough in Plymouth, Leicester, Oldham, Huddersfield, and Hull. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 28 in London, seven in Swansea, three in Sheffield, six in Leicester, six in Hull, and three in West Ham. One fatal case of small pox was registered in Salford and one in Hull, but not one in any other of the 33 large towns, and only one small pox patient was under treatment in the Metropolitan Asylums. On Saturday last, June 10th, the number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2269, against numbers increasing from 2161 to 2212 at the end of the three preceding weeks, 278 new cases were admitted during the week, against 211, 229, and 260 in the three preceding weeks. Influenza was certified as the primary cause of 18 deaths in London. The deaths referred to diseases of the respiratory organs in London which had been 240 in the two preceding weeks further declined to 235 last week. With regard to an outbreak of typhus fever in Salford, the local medical officer, Dr Dewar, "reports that every day there was so little light that he was obliged to light each

Nottingham, Manchester, Leeds, Newcastle-upon Tyne, and in 13 other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Blackburn.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns which had been 16.9 and 19.9 per 1000 in the two preceding weeks declined again to 18.9 during the week ending June 10th, but was 2.5 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14.1 in Leith and 17.6 in Paisley to 21.3 in Dundee and 23.7 in Perth. The 576 deaths in these towns included 25 which were referred to measles 16 to whooping cough, 12 to diarrhoea, six to "fever" five to scarlet fever, and two to diphtheria. In all, 66 deaths resulted from these principal zymotic diseases, against 52 and 68 in the two preceding weeks. These 66 deaths were equal to an annual rate of 2.2 per 1000, which was slightly above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles which had been 11 and 16 in the two preceding weeks further rose to 25 last week, of which 24 occurred in Glasgow. The 16 deaths from whooping cough corresponded with the number recorded in the preceding week, and included five in Leith, four in Edinburgh, four in Glasgow, and three in Dundee. The deaths referred to different forms of "fever" which had been one and three in the two preceding weeks further rose to 6 last week, of which four occurred in Glasgow and two in Dundee. The five fatal cases of scarlet fever showed a decline of six from the number registered in the preceding week and included four in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 108 in the two preceding weeks declined again to 93 last week and were 16 below the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin which had declined in the three preceding weeks from 26.8 to 22.1 per 1000 rose again to 25.2 during the week ending June 10th. During the past four weeks the rate of mortality in the city has averaged 25.2 per 1000, the rate during the same period being 16.2 in London and 18.2 in Edinburgh. The 169 deaths registered in Dublin during the week under notice showed an increase of 21 upon the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against seven and five in the two preceding weeks, of these four resulted from "fever," three from whooping cough, two from scarlet fever, one from diphtheria, one from diarrhoea, and not one either from small pox or measles. These 11 deaths were equal to an annual rate of 1.6 per 1000, the zymotic death rate during the same period being 2.0 in London and 1.0 in Edinburgh. The four deaths referred to different forms of "fever" exceeded the number recorded in any recent week. The fatal cases of whooping cough which had been one and two in the two preceding weeks further rose to three last week. The mortality from scarlet fever also exceeded that recorded in any recent week. The 169 deaths in Dublin last week included 25 of infants under one year of age and 47 of persons aged upwards of 60 years, the deaths both of infants and of elderly persons exceeded the numbers returned in the preceding week. Six inquest cases and five deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1899

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during May in each of the 43 sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7.3 per 1000 of the population, estimated at 4,546,752 persons in the middle of this year. In the three preceding

months the rates had been 85, 67, and 62 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, St George Hanover square, St Martin in the Fields, Holborn, Whitechapel, and Limehouse, while they showed the largest excess in St-Saviour Southwark, St George Southwark, Newington, Bermondsey, Battersea, Greenwich, and Plumstead sanitary areas. Three cases of small pox were notified in London during May, including one in Fulham, one in Marylebone, and one in Lambeth sanitary areas, two small pox patients were admitted into the Metropolitan Asylums Hospitals during May, and one remained under treatment at the end of last month. The prevalence of scarlet fever in London showed an increase upon that recorded in the preceding month, among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Stoke Newington, Strand, St Saviour Southwark, Greenwich, and Plumstead. The Metropolitan Asylums Hospitals contained 2172 scarlet fever patients at the end of May, against 2535, 2272, and 2088 at the end of the three preceding months, the weekly admissions averaged 229, against 236, 196, and 177 in the three preceding months. The prevalence of diphtheria in London showed a marked increase upon that recorded in the preceding month, this disease was proportionally most prevalent in Fulham, St Saviour Southwark, St George Southwark, Newington, Bermondsey, Battersea, Camberwell, and Lewisham sanitary areas. There were 1129 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of May, against 1388, 1159, and 994 at the end of the three preceding months, the weekly admissions averaged 152, against 172, 127, and 107 in the three preceding months. The prevalence of enteric fever in London showed a further decline from that recorded in recent months, among the various sanitary areas this disease showed the highest proportional prevalence in St Luke, Shoreditch, St George-in-the-East, Greenwich, and Lee sanitary areas. The Metropolitan Asylums Hospitals contained 99 enteric fever patients at the end of May, against 215, 148, and 124 at the end of the three preceding months, the weekly admissions averaged 16, against 19 and 17 in the two preceding months. Erysipelas was proportionally most prevalent in Hackney St Giles, London City, Shoreditch, Bethnal Green, and Limehouse sanitary areas. The 31 cases of puerperal fever notified in London during May included five in Islington, and three each in Paddington, Kensington, Camberwell, and Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending June 3rd, the deaths of 6873 persons belonging to London were registered, equal to an annual rate of 15.8 per 1000, against 20.3, 22.2, and 18.0 per 1000 in the three preceding months. The lowest death rates in the various sanitary areas were 10.1 in Lee, 10.3 in Hampstead, 11.0 in Stoke Newington, 11.9 in Battersea, 12.2 in Wandsworth and in Plumstead, and 12.4 in St George Hanover Square, the highest rates were 20.5 in St Giles, 21.9 in St George Southwark, 22.1 in St George in the East, 22.7 in the City of London, 24.5 in Limehouse, 26.4 in Holborn, and 31.6 in St Luke. During the five weeks of May 698 deaths were referred to the principal zymotic diseases in London, of these 262 resulted from measles, 30 from scarlet fever, 129 from diphtheria, 191 from whooping cough, 30 from enteric fever, 56 from diarrhoea, and not one either from small pox, typhus, or any ill defined form of continued fever. These 698 deaths were equal to an annual rate of 1.6 per 1000, against 1.6, 1.9, and 1.6 in the three preceding months. No death from any of these zymotic diseases was recorded last month in St James Westminster or in St Olave Southwark, in the other sanitary areas they caused the lowest death rates in St George Hanover square, Westminster, Marylebone, St Giles, Wandsworth, Lee, and Plumstead, and the highest rates in Holborn, Bethnal Green, St George-in-the-East, Limehouse, St George Southwark, and Newington. The 262 fatal cases of measles were 128 below the corrected average number in the corresponding periods of the 10 preceding years, this disease showed the highest proportional fatality in Hampstead, Hackney, Shoreditch, Bethnal Green, St George in the East, Limehouse, and Lambeth sanitary areas. The 30 deaths referred to scarlet fever were less than

half the corrected average number, this disease was proportionately most fatal in Bermondsey and Greenwich sanitary areas. The 129 fatal cases of diphtheria were 50 below the corrected average number, this disease showed the highest proportional fatality in St Pancras, Clerkenwell, Limehouse, Poplar, Newington, and Bermondsey sanitary areas. The 191 deaths from whooping cough were 98 below the corrected average number, this disease was proportionately most fatal in St Luke, Limehouse, Mile End Old Town, Poplar, St George Southwark, and Newington sanitary areas. The 30 fatal cases of enteric fever were 10 below the corrected average number, the mortality from this disease showed no marked excess in any of the sanitary areas. The 56 deaths from diarrhoea were 12 below the corrected average number. In conclusion, it may be stated that the aggregate mortality in London during May from these principal zymotic diseases was more than 34 per cent. below the average.

Infant mortality in London during May, measured by the proportion of deaths of children under one year of age to registered births, was equal to 110 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Chelsea, Marylebone, St Olave Southwark, Lewisham, Lee, and Plumstead, and the highest rates in Westminster, St Martin in the Fields, Holborn, City of London, Limehouse, and St George Southwark.

THE SERVICES.

ROYAL NAVY-MEDICAL SERVICE

INSPECTOR GENERAL OF HOSPITALS AND FLEETS HENRY MACDONNELL, O.B., has been placed on the Retired List. Staff Surgeon Edward Hanbury Williams has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

ROYAL ARMY MEDICAL CORPS

The under mentioned officers retire on retired pay. Major John W Beatty and Major William G Clements.

INDIA AND THE INDIAN MEDICAL SERVICES

The following appointments are announced.—The services of Captain A F W King (Bombay), are placed temporarily at the disposal of the Government of Bombay for employment on plague duty. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bengal for employment on plague duty. Major H D Rowan, R.A.M.C., Captain O J B Statham, R.A.M.C., Captain R W H Jackson, R.A.M.C., and Lieutenant W E P V Marriott, R.A.M.C. The services of Major H E Deane, R.A.M.C., are placed at the disposal of the Government of Bengal for employment on plague duty. The services of Captain A R S Anderson (Bengal) are placed temporarily at the disposal of the Government of Bengal. The services of Captain W G Pridmore (Madras) are placed temporarily at the disposal of the Government of Burmah. The services of Captain T A Granger (Bengal) are placed temporarily at the disposal of the Chief Commissioner of Assam. The services of Captain P F Chapman (Bengal) are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces. The services of Captain W W Olemesha (Bengal) are placed temporarily at the disposal of the Government of Bengal for employment on plague duty. The services of the under mentioned officers are placed temporarily at the disposal of the Government of the North Western Provinces and Oudh. Captain T W A Fullerton (Bengal) and Captain C B Prall (Bengal).

VOLUNTEER CORPS

Artillery 1st North Riding of Yorkshire (Western Division, Royal Artillery) Septimus Farmer to be Surgeon Lieutenant. **Rifle** 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers Surgeon Lieutenant W Murdoch to be Surgeon Captain. 2nd Volunteer Battalion the Gloucestershire Regiment Surgeon Captain P T Lunn resigns his commission. 1st Volunteer Battalion the Hampshire Regiment Surgeon Captain W K Loveless resigns his commission. 2nd Volunteer Battalion the Durham Light Infantry Surgeon Lieutenant T Livingstone resigns his commission. 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry John McKie to be Surgeon Lieutenant. 1st (Ross Highland) Volunteer

you from personal experience that it is fact, and that by this method of treatment not only do you know the exact state of things but you are running less risk (if any) than in plunging a trocar into a distended abdomen. As to this method of cure we are in the dark and have so far only to accept the fact."

"The details of treatment I carry out are very simple and are as follows: After opening the abdomen by a small incision just below the umbilicus I break down adhesions which in some cases are considerable in the hepatic region; I wash out the abdominal cavity with hot water at a temperature of 112° F until the fluid returns quite clear, and then finding results. One woman was able to join her husband in Australia in a few months apparently completely cured, in other cases apparent malnutrition grew and conditions accompanied by ascites disappeared, and in the rest of the cases the fluid did not accumulate rapidly. In my experience general dropsy contra indicates operation, as here we have to do with causes outside abdominal."

I am, Sirs, yours faithfully,
HARLEY-STREET, W. JUNE 17, 1899. ROBERT O'CALLAGHAN

"SIR GEORGE PULKINGTON, M.P., AND THE MEDICAL REGISTER,"
To the Editors of THE LANCET

Sirs,—With regard to your comments in THE LANCET of June 3rd, on page 1503, on the accuracy of the Medical Register I think it only fair to state that my name, &c., is not recorded as it should be because I refused to pay the fee of 5s asked to make the necessary change of name. As the completeness and accuracy of the Register are of great importance to the public and the way in which my name appears is of no importance to me I declined to be taxed for their benefit.

I am, Sirs, yours faithfully,
Belle Vue Southport, June 5th, 1899. GEO. A. PULKINGTON

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS AT BERLIN
(BY A SPECIAL CORRESPONDENT)

This recent International Congress on Tuberculosis at Berlin presented many points of interest to the British physician. Much valuable information was given concerning the immediate object was to encourage the medical profession and the public in Germany by a record of the progress effected during the last few years, of which that country may well be proud, but the influence of the Congress will be felt in many other civilised countries and notably in England, where after many years' neglect we are beginning to realise the importance of systematic hygienic treatment of consumptives under medical supervision, and of other measures which will probably effect as great a diminution in the mortality from tuberculosis in this country as was effected by the sanitary improvements of the last 40 years.

Dr Köhler's address brought out at once a peculiarity in the incidence of tuberculosis in Germany. Compared with the numbers living at each age group there is a progressive increase with advancing age in the incidence of pulmonary tuberculosis, so that the heaviest mortality occurs at the ages of from 60 to 70 years. Dr Schjerming showed that in the German army the mortality was greatest in those corps which were recruited from densely populated districts, and that whereas workers in industry (regimental baker, musicians and the like) showed a large proportion of pulmonary cases, in the active troops (infantry, cavalry, artillery and pioneers) there was a heavy sickness rate but very little tuberculosis. Mortality from tuberculosis appears to be falling in all civilised countries, especially that from pulmonary tuberculosis, although the improvement is most marked where the most systematic efforts have been made to combat the disease.

It is no longer a matter of doubt that the bacillus of Koch

as follows "Dr Galeotti, representing Professor Lussig, explained the method of preparing his serum and gave some results obtained at several hospitals. He admitted that the results were not very satisfactory up to the present time." I shall feel thankful if you would kindly correct the last sentence of your correspondent who doubtless misunderstood my evidence or which was not correctly reported to him. I did not state before the Plague Commission that the results of serum treatment were not satisfactory up to that time, and had I done so it would have been contrary to what I have already published. I had occasion to express publicly my opinion on the subject—viz., that the results obtained in plague patients with Professor Lussig's serum were generally very good and encouraging, because the mortality amongst the treated patients was about 53 per cent, as compared with a mortality of from 75 to 79 per cent amongst non-treated patients. With the serum of one horse the results were most satisfactory, the mortality being reduced by nearly 40 per cent.

I am, Sirs, yours faithfully,
BOMBAY April 2nd, 1899. DR. GINO GALEOTTI

POISONING BY GELSEMIUM
To the Editors of THE LANCET

Sirs,—The following notes ought to be of interest to the medical profession generally and to toxicologists particularly, because accounts of poisoning by gelsemium are rare.

I took two ounces of the tincture of gelsemium instead of a dram, and returning to the dining room awaited the result. It was not long forthcoming (We all live on the ground floor here). The few feet travelled to the dispensary found me only too ready to accept the receipt of a helping arm and in another minute the legs were paralysed, dragging myself to the bedside with my forelimbs they were unable to help me into the bed, into which I was lifted. There was no trouble so long as I lay quiet but on the next 24 hours. The temperature rose. Vomiting occurred during the next 24 hours. The temperature rose to 101° F. The heart's action was very violent and intermittent, probably the exaggeration of existing disease. All the muscles of the eyes must have been affected but of all the voluntary muscles those of the right side suffered most. Prolonged convulsion involved paralysis of the upper lip. The other symptoms were (1) somnolence, (2) no mental excitement and (3) good appetite. The effect of the drug passed away as it began, from below upwards, but after the arms had recovered vision was not perfect for 24 hours. It thus appeared to have been so ready to give you an account of the effects of gelsemium removers.

I am, Sirs, yours faithfully,
J. H. KATZMELT,
Blastic, Surgeon.

"CURE OF ASCITES DUE TO LIVER CIRRHOSIS BY OPERATION"
To the Editors of THE LANCET

Sirs,—I have read with much interest the paper on the above subject by Mr. Rutherford Morton in THE LANCET of May 27th, especially as I think that I was the first to advocate this method of treatment in these cases, and which I have practised with comparative success since 1888. You will kindly allow me to quote briefly from a paper of mine read at the Surgical Section of the Royal Academy of Medicine in Ireland. "When I meet with a case of distended ascitic abdomen I do not, under any circumstances, try it as my practice to open the abdomen, prepared for any emergency by an incision sufficient to admit my finger which will enable an experienced surgeon to ascertain in a minute the exact condition of the ascites. Should it only happen to be simple ascites the fluid will not re-accumulate for a much longer period than it happened to be a complete abstinence for an indefinite period of the fluid and urgent symptoms and in some cases a mischievous asphyxia of the growth. This may seem to some of you heretic and incredible, but I can assure

obvious. These are furnaces for the destruction of dead organic matter and they are found in practice to do this effectually and completely and they do not render either large or small areas uninhabitable, unsanitary, or unpleasant even when situated in a thickly populated district. The medico legal argument is the one which has been most prominently pushed forward by the advocates of the earth-to-earth system. They contend that homicidal crimes such as secret poisoning and stabbing would be rendered less easy of detection consequent on the early and complete destruction of the body and therefore the impossibility of subsequent exhumation and so an increase in such crime would take place. Sir Francis Haden³ states that this is a part of the subject which no cremationist is willing if he can help it to hear mentioned. Now, so far from this being true, all cremationists recognise that this at first sight is a serious objection to their method and they have over and over again called attention to it publicly—for example, the speeches delivered by Dr Cameron and Sir Lyon Playfair in the House of Commons on the Disposal of the Dead (Regulation) Bill on April 30th, 1884.⁴ As regards poisoning, experiments instituted by M Cadet and repeated by M Dourvault and M Worst have shown that arsenic and all mineral poisons (except mercury) can be detected just as well in the ashes of a burnt body as they can be in an exhumed body. The organic poisons are destroyed just as much by interment as they are by fire, only, of course, not so quickly. But the remedy for this possible evil would be (and this is needed whatever system we adopt) to appoint State officials, as is done in France and Germany, to inquire into and verify the death certificate. In the majority of cases no difficulty would arise and in any suspicious case the proper authorities could be notified and an investigation held. The detection of crimes of this character is quite rare unless the criminal is discovered at once, after burial it is exceedingly uncommon for suspicion to arise. The average number of exhumations, for instance, in this country is only five per annum, and of these less than one is for suspected poisoning. As a matter of fact, crime would be more likely to be detected, not less, if we could make it statutory that a verification of death should be undertaken by some independent official before a body is destroyed by cremation. To my mind the objections to cremation can all easily be disposed of. It is from all points of view the ideal system for adoption in the future for disposing of the dead.

I am, Sirs, yours faithfully,

L A PARRY, MD Lond, F R C S Eng,
Honorary Anaesthetist to the North West
London Hospital.

Bartholomew road, N W, May 30th, 1899

THE GENERAL MEDICAL COUNCIL AND THE PROPOSED CONCILIATION BOARD

To the Editors of THE LANCET

SIRS,—It must be allowed, I think, that the idea of bringing together the representatives of the friendly societies and the members of the medical profession is a good one. At the same time it must be apparent that the General Medical Council have not gone sufficiently into detail in their scheme.

We are all aware that the friendly societies possess at the present moment a thoroughly workable organisation and that they are prepared at a very short notice to nominate and elect men to represent them on a conciliation board. On the other hand, it is evident that the medical profession have no such organisation to deal with such a question. The point which appears to me of the greatest importance is: How are the representatives of the medical profession to be elected and by whom? I submit that neither the British Medical Association nor the medical defence societies could undertake such a duty. What I propose for the consideration of the profession is the formation of an association of medical officers connected with friendly societies. Let a conference be called of such officers at an early date and let it appoint a committee to formulate a scheme for the establishment of a permanent association. In the meantime perhaps you, Sirs, will permit your columns to be used for the discussion of this very important subject. I cannot conclude without expressing the satisfaction which is felt with the decision of the General Medical Council in respect to the connexion of

the medical profession with those particular associations which combine medical aid with life insurance.

I am, Sirs, yours faithfully,

Cardiff June 10th, 1899.

T GARRETT HORDER.

To the Editors of THE LANCET

SIRS,—The resolution of the General Medical Council, "That this Council regards it as unprofessional to hold the appointment of medical officer to associations which systematically practise canvassing and advertising for the purpose of procuring patients," is a step in the dark, and one which may involve endless troubles and worry to medical officers of clubs all over the country. Who is to decide what is systematic canvassing and advertising? All the large friendly societies canvass and advertise, but the Council dare not touch their medical officers, for they have a strong Parliamentary vote behind them. It is the medical officers of the small clubs, generally young struggling practitioners, who will be the ones to suffer. Some medical neighbour, smarting at some real or supposed interference with his patients, will report the club to the Council, and the medical officer, dreading the expense and worry of defending himself, will have to resign. The result will be that the great friendly societies will soon exterminate the smaller clubs and our younger men will have to start as assistants to the present club medical officers and be sweated by them instead of obtaining independent practice. From a professional point of view the want of a wage limit and inadequate fees are far more objectionable than canvassing, for after all there are but few patients who will change their medical man at the request of an agent unless he can offer them better terms. The resolution of the Council practically makes the medical officer responsible for the action of all the agents of the association, with the fearful penalty of utter professional ruin if they are detected canvassing. If it applied to all clubs it would not be so objectionable, but a knowledge of modern politics teaches us that it can and will only be applied to the weaker ones. If the friendly societies refuse to accept a wage limit, which is the key to the whole matter I fail to see what good can come out of the board of conciliation.

I am, Sirs, yours faithfully,
X.

June, 1899

THE MICROCOCCUS OF BERI-BERI

To the Editors of THE LANCET

SIRS,—I came recently across, in THE LANCET of June 25th, 1898, a communication from Dr W K Hunter in which he speaks of a staphylococcus with rapid motion to be found in the blood of beri beri patients and suggests that it may be the cause of the disease. I have long been cognisant of a micrococcus easily grown from blood and spleen on agar or gelatin, the growth being non-penetrating, greyish in colour, raised, and having very ragged edges. These cocci are most motile and the fresh blood in some cases is frequently crammed with them. With few exceptions the blood of all my beri beri patients contained them. Wishing to inoculate some animals with these cocci I was unable to obtain any whose blood was not already rich with them. Later I found that many healthy patients had them in quantities and still later that they were present in the blood of myself and other European officers. This was now nearly two years ago, since which time I have been quite healthy and, I may mention, have never in my life suffered from any symptom of beri beri or from fever of any description. A few of my patients suffering from beri beri have had their blood quite free from the cocci throughout their attack. I have long come to the conclusion that the coccus is non-pathogenic and is contained in the blood of the majority of people living in this colony. Probably it is derived from meat, as so many animals possess it in such abundance.—I am, Sirs, yours faithfully,

W GILMORE ELLIS,

Medical Superintendent of the Government
Singapore May 8th, 1899. Lunatic Asylum Singapore.

THE PLAGUE COMMISSION

To the Editors of THE LANCET

SIRS,—My attention was only recently drawn by a friend to a report of the evidence taken by the Indian Plague Commission at Bombay and which is published in THE LANCET of Dec 24th, 1898, p 1740. I find that I have been reported

³ THE LANCET May 27th, 1899

⁴ The Times, May 1st, 1884

as the chief cause of tuberculosis, although it is still disputed how far the clinical features of phthisis are due to other associated bacteria. In this respect Pfeiffer holds different views from those advanced in this country by Kingston Fowler and others, and believes that the hectic fever of phthisical patients is entirely due to "mixed infection." There was a general consensus of opinion that tuberculous milk was a most important cause of tuberculosis in mankind, and that apart from the systematic inspection of dairies and prohibition of the sale of infected milk much could be effected without legislation if everyone insisted on being supplied with milk from tuberculin tested cows. An important communication from Obermüller dealt with the question of tubercle bacilli in butter. There has been some controversy as to whether infection can take place through this article of food, as the bacilli found in some specimens were said to be examples of an allied bacillus (Petri's butter bacillus) capable of producing anatomically similar lesions in animals whilst less dangerous to man. From the experiments of Obermüller and Fri Rabinowitsch, confirmed recently by Koch, it appears that undoubted living tubercle bacilli may be found in butter, and the former recommends that the butter be made from pasteurised milk as being both safer and more economical. It is stated that in some parts of Germany as many as 60 per cent of the cattle are tuberculous, but it is well known that those kept in the open (especially in hilly or mountainous districts) are but little affected. According to Schumburg tubercle bacilli are only found in butchers' meat when there is advanced disease with cavities, but it must be remembered that lymph glands, lymph tracts, and bones are frequently affected, and tuberculous material may be smeared over sound portions of the animal. Flüge insisted on the identity of the bacillus of mammals with that of man, while the identity of avian tuberculosis was not established. He regards the tubercle bacillus as the sole cause of all the symptoms of tuberculosis in man and considers the bacillus as an obligate parasite in man and animals, excluding purely artificial cultivations. Fränkel insisted on the truth of Flüge's views as to the pulverisation of sputa in coughing and sneezing, and pointed out that the chief danger of transmission was in the immediate neighbourhood of the patient, as light and desiccation speedily kill the bacillus, and the disease is further limited by the resistance of the healthy organism to all but large and repeated doses. It was recognised that the danger of transmission exists chiefly in overcrowded and dirty rooms and in dusty workshops. Rubner advocated the separation of sick from healthy workmen and the dismissal of susceptible subjects from unhealthy trades. Leube advocated the use of wadding masks during the bed making and cleansing of rooms in hospitals and the like. He regarded segregation of phthisical patients in general hospitals as more needed in the interests of the patients themselves than to prevent spread of infection. Out of 312 consecutive cases of phthisis recorded by von Zander infection could be proved in 116 (or 37.3 per cent). In 20.1 per cent this was transmitted from a relative, in 6.7 per cent from husband or wife, and in 10.5 per cent from fellow workmen or the unrelated occupants of the same room.

Löffler argued that inheritance of the disease might be disregarded as only a pathological curiosity, while an inherited tendency, although probable, had not been proven. Roth urged the importance of early diagnosis and the value of sanatoria from an educational point of view, the need of systematic instruction of the members of sick clubs and in workshops and the like, the need of special arrangements in schools and prisons which have phthisical or susceptible inmates, the care of convalescents, and prompt isolation of phthisical subjects who expectorate bacilli. He also advocated that affected persons should be forbidden to act as wet nurses or sick nurses or in the preparation of food. He was in favour of notification of cases of tuberculosis in private nursing homes, asylums, almshouses, and the like, and in private houses where a change of abode occurred, so that disinfection and other protective measures could be enforced. No doubt this would be easier in Berlin (where everybody has to notify his arrival to the police) than in England although even in this country voluntary notification (e.g., at Brighton) was worked well. Roth further advocated the separate disinfection of clothing used by phthisical subjects and thorough disinfection of bedding and rooms after death.

Kirchner discussed the question of marriage of phthisical subjects, and although satisfied that compulsory prevention of such marriages was impossible, yet urged that full information should be given by the medical man wherever they were contemplated, and special precautions taken both for the sake of the patients and of their offspring and those living with them. Everyone is nowadays agreed as to the importance of properly dealing with the sputa of phthisical patients. Ritter von Weismayr recommended that the sputa should be thrown into the water-closet or mixed with peat and burnt, or with lime and buried, and that random spitting should be forbidden. An interesting paper was read by Malvoz on the Bacteriological Institutes in Belgium which gratuitously examine sputa and disinfect rooms, half the cost being borne by the State. In order to teach phthisical members of the working class how to conduct themselves it has been found necessary to erect a popular sanatorium in connexion with one of these institutes.

The enormous extension of the sanatorium treatment in Germany under the influence of the Insurance Law makes it quite impossible to deal with the subject there. The existence of immune zones is no longer a tenable hypothesis, and healthy places of many kinds are now regarded as sufficient for the cure of patients by systematic measures. As regards treatment, apart from a masterly paper on Climate by Sir Hermann Weber and a description of the methods used and the good results obtained at Ventnor by Sinclair Coghill, the chief interest for British members centred in the papers of Kobert, Landerer, Brieger, Denys, and Campana. Iodoform was regarded by Kobert as the best remedy for surgical tuberculosis, and orthoform and lactic acid for laryngeal complications. Military and galloping tuberculosis were considered to be incurable, while cases of ordinary phthisis could be readily arrested by the hygienic and dietetic methods associated with Brohm's name, aided by ordinary symptomatic treatment. Kobert and Landerer both praised the use of cinnamic acid to provoke leucocytosis. Brieger still regards tuberculin as useful in early stages and is supported by Campana of Rome, and by Denys of Louvain who uses a special preparation. The use of anti-tuberculous serum as prepared in America was advocated by von Schweinitz who also quoted Stabbert in support.

To sum up, the general impression left by the Congress was that while no specific has yet been discovered we have in the shape of systematic treatment by hygienic measures, especially in suitable sanatoria and health resorts most potent and sufficient means of treatment in all early uncomplicated cases of phthisis, while still more is possible in the way of prevention.

NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT)

The Transport of Plague Microbes—Stringent Regulations—The Misfortunes of Karachi—Plague and Cholera—Minor News.

It will be remembered that in June of last year two cases of plague occurred on board the steamer *Carthage* on her voyage to Europe. It so happened that a medical man who was a passenger made during the voyage some experiments with what were supposed to be plague microbes. No dead rats were found on the homeward voyage but at least two were found on board the vessel on her return voyage to Bombay. The result of these coincidences appears to be that the Government of India have thought it necessary to make the following regulations:—
 "1. No person without the written or printed permission in this behalf of the local government in whose territories the port is situated under the signature of a Secretary to Government first obtained, shall take either on his own person or in any baggage or parcel or as cargo or otherwise howsoever, or shall send or permit to be taken or sent on his account either on the person of another or in any baggage or parcel or as cargo or otherwise howsoever any plague microbes or cultures on board any vessel in any port in British India.
 "2. No person, whether he has or has not obtained permission as herein before required, shall take, send, or permit to be taken or sent as aforesaid any such microbes or cultures on any such vessel at any such port unless and until he has (1) given

to be paid by the corporation for the purchase of the whole of the infirmary site is said to be £400,000

June 13th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Consumption Hospital for Dundee

SEVERAL considerable sums of money have already been promised as contributions towards the erection of a hospital for consumption in Dundee. The committee appointed to raise funds for the building met on June 2nd. At that meeting it was decided that the hospital should be available for all classes of patients either with or without payment, the matter being under the control of the directors. It is desired that subscriptions should take the form of capital sums as endowments or of annual subscriptions. Subscribers of £1000 and upwards shall during their lifetime have absolute presentation to one bed. Steps are being taken to secure a site for the hospital. The high ground in the Carse of Gowrie has been suggested as a suitable situation.

Cottage Hospital for Blairgowrie and Rattray

It is expected that in about a month the building of the cottage hospital for Blairgowrie and Rattray will be commenced. A site of about an acre in extent has been given by Mrs Macpherson of Blairgowrie and £3000 have already been subscribed towards the building fund, £1000 having been given by Lieutenant-General Sir James Olerik-Rattray of Craighall and £500 each by Mrs Nicoll of Blairgowrie and Sir William Laird of Glasgow. The estimated cost of the building is £1000, but at least £5000 are needed for furnishing and partial endowment of the institution. The district for which the hospital is intended extends from Glenshee and Strathardle in the north to Coupar Angus in the south, and from Alyth in the east to Olaverie in the west.

Infectious Hospital for Lockerbie District

Negotiations are proceeding between the burghs of Moffat, Lockerbie, and Lochmaben with reference to the creation of a joint hospital for infectious diseases.

Gift to Paisley Infirmary

Mr Peter Coats, Paisley, who has already been a large contributor to the erection of the Paisley Infirmary and who has built a handsome home for the nurses of the institution, has just offered to build an additional block to the infirmary for the treatment of infectious diseases. The new block will be 24 feet by 14 feet, and will contain a male and a female ward, each to accommodate three patients, and there will be a lavatory, bath, and nurses' accommodation.

Death of Mr Robert Moir, M.D., F.R.C.S. Edin., St. Andrews

Dr Robert Moir, who had been ill for about a fortnight, died at St Andrews on June 7th. Dr Moir was the second son of "Delta," the late Dr Moir of Musselburgh. He was in his sixty-ninth year and took a prominent part last year in his father's centenary celebrations. Dr Moir had practised in St Andrews for the last 25 years and previously was a surgeon-major in the Indian army. He has left a widow, three sons, and three daughters to mourn their loss.

The Cemetery Scandal in Aberdeen

During the past week investigations were carried on in Nellfield Cemetery under a warrant from the sheriff, obtained on the motion of the Crown officials. The operations extended over four days, Professor Hay, M.D. Edin., being present as medical expert. The general public and pressmen were excluded while the Crown examination was being conducted, but the reporters for the evening papers stationed themselves in high windows or back gardens adjoining the burying ground and published alarmist reports of gruesome discoveries having been made. The reading of these reports has produced much mental disquietude among lairholders, one at least of whom has died from the excitement so caused, while huge crowds were also drawn by morbid curiosity to the cemetery when it was reopened to the public in the evenings. There have also been manifestations of popular indignation against the factor of the Baker Incorporation, although it is pointed out that none of the irregularities complained of have taken place during his term of office. Private lairholders have likewise been making examinations of the portions of ground belonging to them.

On June 10th William Coutts, the late superintendent, was again brought before the sheriff, when nine fresh criminal charges of desecration of graves and mutilation of bodies were preferred against him. His application to be admitted to bail was refused in view of the serious nature of the charges and he will be tried before the High Court of Justiciary in Edinburgh. It is expected that Dr Hay, in his capacity of medical officer of health of the city, will make a report to the local authority under the Public Health Acts as to the system of overcrowding which has prevailed in the cemetery, while two members of the town council have given notices of motion to the effect that the municipality shall provide a new and properly regulated burying ground to be managed by the municipal corporation.

Conference in Aberdeen on Tuberculous

Representatives from the Aberdeen Town Council, the Royal Infirmary, the Dispensary, the Royal Hospital for Sick Children, the Parish Council, the Morningfield Hospital, and the local branch of the British Medical Association met in conference last week. It was agreed that a sanatorium ought to be provided. Doubts were expressed as to the power of the town council to erect and maintain such an institution at the cost of the local assessments, but it was agreed that if tuberculous diseases are not at present embraced in the list of notifiable infectious diseases, steps should be at once adopted in order to secure their inclusion.

June 14th.

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Royal College of Surgeons in Ireland

At the recent election at the Royal College of Surgeons in Ireland for the President, Vice President, and Council, Mr Robert L. Swan and Mr Thomas Myles were re-elected as President and Vice-President respectively. The only changes in the personnel of the Council were the replacement of Mr Henry Croly, Mr Arthur Benson, and Mr Arthur Chance, by Professor John B. Story, Professor William Stoker, and Mr Richard McCausland. There will be a vacancy for the position of Vice-President in next June, when Mr Myles will enter on his two years of office as President. The candidates who have already announced their intention to contest this vacancy are Mr Francis Heuston, surgeon to the Adelaide Hospital, and Mr Lambert Ormsby, surgeon to the Meath Hospital. A letter from the latter gentleman on this subject appeared in THE LANCET of June 10th.

Action for Damages against a Medical Officer of Health

Dr Joseph Smyth of Naas has recently obtained a legal decision in his favour, which is of importance to all medical officers of health. In that capacity he made a report some months ago advising that a certain dairy establishment in the neighbourhood of Naas should be closed, two cases of typhoid fever having occurred in the house of the owner of the dairy, and five persons who obtained milk from that establishment having also suffered from the same disease. The proprietor of the dairy brought an action against Dr Smyth for £1000 damages for injury to his business. The case came quite recently before his Honour Judge Kane who dismissed the action on the ground that to recover damages in such a suit malice on the part of the medical officer of health should be proved. As far as the published reports of the case go there was not even an assertion of malicious action on the part of Dr Smyth.

Presentation to Dr Dysart, J.P., of Portlengone

Dr Dysart, J.P., Portlengone, co. Antrim, has been presented with a silver tea and coffee service and silver bowl together with an illuminated address on the occasion of his resignation of the position of medical officer of the Portlengone dispensary district after a long and honourable service of 51 years. A purse of sovereigns was also presented to Mrs Dysart. Dr Dysart has been for a long period one of the most respected and valued medical men in the county of Antrim.

Report on the Belfast Workhouse

Mr Agnew, the Local Government Board inspector, has made his half-yearly report on the state of the Belfast Workhouse. He refers to the serious overcrowding and want of proper sanitary accommodation in certain departments of the establishment, to the objectionable state of some of the closets in the infirmary, to the non-observance of

of 10 centigrammes (one and a half grains) a day ought not to be exceeded, on an average from two to five centigrammes should be given in 24 hours. The injections should be continued for seven or eight days, then stopped and resumed as before after a week's interval. When Professor Gautier had brought his communication to a close remarks were made by several members of the Academy, including M G Hayem and M A Robin, who said that it was quite unreasonable to presume a similarity between treatment with cacodylic acid and treatment with arsenic, as Professor Renaut had done, the former being essentially a stimulant whilst arsenic inhibited tissue change.

Compensation for the Slaughter of Tuberculous Animals

In France animals found to be tuberculous are slaughtered under the official regulations and the carcasses are seized, an occurrence which has become much more common since tuberculin has been employed for the early diagnosis of tubercle in animals. The law of April 13th, 1898, has provided for the payment of compensation to the owners of animals sacrificed in this way in the interests of public health. The compensation is on the following scale: (1) when the tuberculosis is very extensive one-third of the animal's value at the time of slaughter, (2) when the disease is localised three-fourths of this value; and (3) when the carcass of an animal slaughtered by official order is found to be free from tubercle the full value of the animal as above. In all cases the price of the meat and offal sold by the owner, with the permission of the *maire*, is deducted from the compensation above mentioned. Compensation must not exceed 200 francs (£8) for one-third of the animal's value and 450 francs (£18) for three-fourths of its value.

June 14th.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Self inflicted Injuries Diagnosed by the Roentgen Rays

A FRESH proof of the practical utility of the Roentgen rays has been supplied by a case published by Oberstabsarzt Dr Baehren of Wiesbaden. A soldier who alleged that he had been bitten by a horse was admitted into the military hospital with a swelling of the third finger, especially marked at the tip and extending to the back of the hand. A sinus developed after several weeks in the neighbourhood of the joint between the first phalanx and the metacarpal bone and the introduction of a probe showed the bone to be denuded of periosteum. The sinus healed up after being laid open and cauterised, but the swelling continued and the mobility of the finger was impaired. An examination of the hand by the Roentgen rays resulted in the discovery of five needles in the second and third interosseous spaces of the metacarpus. There was also a small, scarcely visible, sinus in the fold between the second and third fingers. On the following day the skiagraphic examination showed only four needles the man having extracted one of them through the sinus. All the needles were removed by a large incision and the hand became quite normal. The man at first pretended that he did not know how the needles had come into his hand, but he afterwards admitted that he had introduced them because the hand was painful and he expected relief from the escape of blood. He had evidently inflicted these injuries on himself in order to obtain his discharge from military service, not foreseeing that by the aid of the x rays his imposture would be detected.

General Practitioners in Surgical Cases

The professional competence of general practitioners has been gravely called in question by a judgment pronounced in a law court of Charlottenburg, a suburb of Berlin. A general practitioner being asked to see a child who had fractured his femur called in a surgical specialist who applied a bandage and made no further attendance but left the after treatment to the general practitioner. Evidently the bandage was too tight, a fact which escaped the notice of the general practitioner, gangrene set in, amputation became necessary, and the general practitioner was thereupon prosecuted. The court, after having heard the opinion of several medical experts, adjudged him not guilty for the following curious reasons: (1) that the disastrous issue of the case was not attributable to the general practitioner but to the specialist who had been

consulted and who had left the control of the bandage to a general practitioner, and (2) that the court was of opinion that a general practitioner without special surgical training ought not to be allowed to have charge of severe surgical cases. The *Deutsche Medicinische Wochenschrift* in discussing the circumstances rightly points out that this decision impugned the reputation of the medical profession in general, and was moreover at variance with medical ethics, for it would have been an infringement of medical etiquette if the surgeon had continued his visits without having been asked to do so by the medical attendant of the family. The article goes on to remark that this decision tended to induce the public to abstain from consulting general practitioners when surgical questions were involved and that the medical societies ought to protest against the suggestion of the law courts that none but surgical specialists were competent to attend surgical cases.

The Sick Clubs

According to a publication issued by the Imperial Statistical Office there were 22,477 sick clubs under the workmen's insurance laws in 1897, against 22,011 in 1896 and 21,588 in 1892. The number of members was 8,337,319, the number of patients was 2,964,937. The income of the clubs was 16,781,000 marks (£839,000), the expenses were 13,394,000 marks (£669,700), of which 12,049,000 marks (£602,450) were paid for treatment in hospitals or by medical officers, for medicines and bandages, and for the maintenance of the patients and their families, the rest being general expenses for club offices, treasurers, clerks, &c. These large numbers show how great must be the influence of the clubs on the condition of the medical profession and on medical matters in general. The clubs were invited to send delegates to the Congress on Tuberculosis and a great number of them actually attended. A congress of sick clubs was, moreover, held simultaneously with the Congress on Tuberculosis and objections were made to the resolutions of the Practitioners' Associations concerning the compulsory "free-choice system."

June 13th.

ROME

(FROM OUR OWN CORRESPONDENT)

Hydrophobia

ISTITUTI ANTIRABICI are now established and in working order at nearly all the great centres—Naples, Rome, Milan, Turin, and, finally, Florence—having each its effective institution for the treatment of rabies canina communicated by dog bite to the human subject. Their annual reports are generally as satisfactory as they are interesting, and Milan especially has a sustained record of cures hardly inferior to that of the Pasteur Institute itself. But there are many innovations to be brought into the relieving service of the provinces before these institutions can give the poorer class of victims the full benefit of their treatment. Let me illustrate the situation by a concrete instance. In a country village, several hours distant by rail from the Istituto Antirabbico, a dog, of unknown origin or antecedents bites about a dozen persons, the animal is caught but not killed as "mad," till after 40 days, and meanwhile the bitten subjects, with no time to lose, must be made to undergo the appropriate treatment. But how are they to be conveyed to the Istituto and once there how are they to be maintained? In law the commune in which the village lies is not bound to undertake their transport or maintenance, this is a fact, tested and decided by appeal to the Consiglio di Stato and the Court of Cassation. Recourse is therefore had to the local Congregazione di Carità, but these benevolent societies are oftener than not too heavily drawn upon by other necessitous cases to have the required subsidy at their disposal. Failing this, there is an appeal to private charity—again rarely responded to, "non possumus" or "my poverty but not my will, consents," being the justification of refusal. In despair the wretched "moralisti" (bitten subjects), knowing they have not an hour to lose and haunted by a terror that reduces their chance of cure, apply to the local "gombeen man" or usurer, but his rate of interest is too high and the money cannot be raised though it amount to no more than 60 francs (£2 8s 4d) per

head So for such cases the Istituto is practically non-existent, or it is of little use, or an appeal to the general public for the money is at last forthcoming the time lost deprives the poor victims of whatever chance the Istituto could vouchsafe them So the dread

malady runs its course, the victims die in excruciating agony, if, indeed, they do not fatally inoculate the young bands that tend them through the closing scenes "I'll a proper assistance Rubique is established the Istituto, I repeat, are usually closed to all but the citizens in their immediate neighbourhood or to such prominent as can afford to come to them "Two months ago in the Canares district (Alta Italia) one dog bit 12 people and numerous other dogs belonging to eight communes in the neighbourhood Hygienic precaution counselled the destruction of these dogs, but the owners would consent to no such step and the animals were kept "in asserazione" for several incantations persons At San Martino (still) in the Canares district) an individual whose dog was bitten by the mad dog above referred to kept his own animal 52 days "in asserazione," till seeing it in apparent good health he unchained it with the result that a few days later it bit his own son whom (fortunately for him) he was rich enough to send to the Istituto Antibiotico at Turin A brilliant exception to the somber rule which I have just been indicating reaches me from Cigliano in the province of Asti A dog, unknown to the inhabitants, bit 14 of them and several other dogs and was thereafter caught and killed The Syndic of Cigliano, nobly anxious for the health of his fellow citizens, had the victims all sent to the Istituto at Turin while the Commune of Cigliano undertook what must have been the grave burden of boarding and lodging the said victims during all the time of their treatment, the cost amounting to over 7500 fr (230) Why cannot similar provision be made in like circumstances in all communes throughout the Kingdom? But Cigliano is exceptional well to do I am told Then what is the Government about? The Government, between its Abyssinian and its Chinese annexations and the military and naval expenses which it has to meet, is so desperate for money that, as mentioned in these columns on the authority of the Prime Minister, General Pelloux, it can afford for the 8636 communes in the Italian Kingdom no more than 8000 fr (2320) for all hygienic purposes whatever—that is, about sixpence for each commune! I have not heard of any legislation being introduced to meet this scandal, except, indeed, a Bill to enable communes to borrow on advantageous conditions But as these communes are generally deep in debt if carried, will do little or nothing for the health or the lives of the leges How long is this to last? Or when will "that blessed word" "patienza" cease to paralyse reforms?

The Behaviour of some Compounds of Iron in Artificial Digestion

At a recent meeting of the Reale Accademia di Medicina in Turin an important paper on the above subject was communicated from the Chemical-Physiological Laboratory directed by Dr Piero Giacosa, Professor of Materia Medica in the sub-Alpine school The researches and conclusions which it embodied were the work of Signor Gola, student in medicine He examined various specimens of the albuminates of iron according to the prescribed methods, and thereafter he examined the pectonates and the "ferratin" of commerce besides the "classical reaction" of the sulphide of ammonium employed a new reaction of the albuminate of iron. The results of his researches are given in the addition to the ammonium solution of the preparation in question of some drops of an aqueous solution of hydrogen peroxide which is coloured blue with the ferratin and a violet red with the organic compounds of iron He concluded that the albuminates have reactions of "organic iron," while the pectonates and the "ferratin" of commerce comport themselves like the common citrates and lactates of iron. Referring to the researches of Professor Cerrillo of Palermo on the absorption of medicinal iron in the intestine he took the various compounds already studied and the citrate and the lactate, and the perborate of iron and subjected them to artificial digestion with albumin in gastric juice and in pancreatic juice and to the double

THE LANCET Oct 22nd 1893, p 1093

gasitic and pancreatic digestion The results were these—The albuminates, the pectonates, the "ferratin," and the perborate of iron, mingled with albumin, yield, after digestion, a reaction of organic iron, while the citrate and lactate preserve their inorganic nature, the transformation takes place if the albumin is mingled with the preparation in *vis digestions*, whence may be deduced a confirmation of the old practice of exhibiting the preparations of iron at meals rather than in the fasting stage

"Cholera in Poultry"

In spite of a "fall-dress debate" in which the leading bacteriologists of the sub-Alpine school took part at a largely attended meeting of the Reale Accademia di Medicina the etiology and pathology of this very serious epidemic remain *in statu quo* There is, in fact, nothing to add to the brief summary of Dr Mazzara's paper and its criticism by Professor Peronitto and Dr Abba published in THE LANCET on June 3rd The weighty authority of Dr Foa, professor of pathological anatomy, was given in favour of the non-choleric view of the origin and character of the disease, while this may be held to have been balanced by the equally authoritative evidence of Dr Belfanti of the Milanese Bacteriological Institute who found what he claimed as the cholera bacillus in the infected poultry In his summary up the President (Professor Bozzolo) recommended further investigation

JUNE 12th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Health of Sydney

THE quarterly report of Mr T M Kendall, medical adviser to the Board of Water supply and Sewerage, Sydney, showed that the population of the metropolitan area had considerably increased—to the extent of 11,600 persons The number of deaths from all causes was greater than the total for the corresponding quarter of last year, the chief increase being from whooping-cough, measles, typhoid fever, and phthisis The mortality from diarrhoea had notably diminished A careful inquiry was made into the circumstances of the 41 cases of fatal typhoid fever and it was found that in 21 cases sewers had not been laid, in two cases sewers had been laid but the houses had not been connected, while 17 cases occurred in insanitary dwellings No fatal cases occurred in dwellings properly provided with sanitary appliances

Health of Melbourne

From the annual report of the medical officer of health of the city of Melbourne it appeared that the total number of deaths for the year was 1196, a considerable increase on the average of the last few years, the rate being 16 per 1000 The concurrence of epidemic outbreaks and unprecedentedly high temperature was regarded as the cause of the increased mortality The chief causes of death were typhoid fever, measles, whooping-cough, diphtheria, croup, and influenza There was a considerable increase in infantile mortality, chiefly from diarrhoeal diseases as usual, tuberculosis caused the greatest number of deaths

The Medical Curriculum of the Melbourne University

The course of study at the Melbourne Medical School has been for many years felt to be inconvenient and unsatisfactory and the Faculty of Medicine has been discussing the bringing the curriculum more into harmony with the recommendations of the General Medical Council of the United Kingdom The Faculty has drawn up a report which has been presented to the Council of the University The Faculty finds three chief faults in the present curriculum—(1) The working year is too short, (2) It is overcrowded with systematic lectures, and consequently (3) there is not sufficient time for practical work, particularly clinical work The Faculty recommends that the working year be lengthened so as to comprise three terms of ten weeks each The main examination would thus be placed in the middle of the second term and the old place at the beginning of March being deleted and its place at the end of the year. Final honours would be awarded now with the main pass examination, under the same conditions and honours in the earlier years of the curriculum. The University the practical course at the School of Pharmacy being compressed and improved. Junior anatomy and senior anatomy would

be reduced from three to two lectures a week. Regional and applied anatomy and dissections of the fourth year would be abolished. The routine work of practical pathological histology would be transferred from the fourth year to the third. Therapeutics, dietetics and hygiene, obstetrics and diseases of women would extend over two terms instead of three. Medicine and surgery would be one year's courses instead of two. Forensic medicine lectures would be reduced to one lecture instead of three lectures a week. But better practical teaching would be aimed at in all subjects. Thus the hospital work of the second year would be reduced to two terms and preceded by a general anatomical excursus. Special tutorial instruction in elementary surgery and elementary medicine would be required during two terms in the second and third years respectively. Practical demonstrations in therapeutics, dietetics and hygiene would occupy one term. Practical gynaecology would be compulsory. An attempt would be made to constitute a course of practical demonstrations in forensic medicine and partly optional classes would be established in diseases of children, diseases of the eye, diseases of the skin and mental diseases. The Faculty finds that under existing regulations the number of Bachelors of Medicine and Surgery who proceed to higher degrees is extremely small. The conditions imposed on candidates for M.D. are very rigid, very troublesome without a corresponding amount of efficiency. The Faculty advises a complete alteration in the requirements for the degree of Doctor of Medicine and a modification of those for the degree of Master of Surgery. For the Doctorate it recommends a thesis in any subject of the medical curriculum with an examination in clinical medicine, such examination being dispensed with when the thesis is of great merit and originality. For the Mastership it suggests the elimination of logic, the simplification of the examination in surgery (without any reduction in standard) and the grouping of surgical anatomy and pathology into one subject, so that excellence on one side would atone for some degree of weakness on the other. In the clinical examinations students of special departments would have certain privileges.

The proposals of the Faculty were sharply criticised in the Council, objection being taken that too much time and attention were given to biology and physics in the first year and that the final year was still too much occupied with systematic lectures. After discussion the Council accepted the proposed curriculum, subject to the consideration of the details of the science subjects of the first year. The senate will now have to deal with the matter and further opposition to the Faculty's proposals is anticipated.

The Sydney Medical School

The April number of the *Australasian Medical Gazette* contains an editorial article on the Sydney Medical School in which attention is drawn to the overcrowding of the profession by locally educated men and the question is asked, "What useful contributions have been made by the professorial staff of the Medical School to the advancement of medical science? What have we to show for the £80,000 spent on the Medical School?" and the reply is "Nothing whatever—but the overcrowding of the profession and the impoverishment of the majority of efficient and hard working medical practitioners." The professorial staff will probably reply to this attack in suitable fashion, but it may be pointed out that a good deal of original work of value has been done in the Sydney Medical School by Dr Anderson Stuart, Dr O J Martin, Dr Wilson, and others, and that the burden of teaching under the present conditions is too great to allow leisure for much original research.

Dispute at the Yarra Bend Hospital for the Insane, Melbourne

The members of the Public Service Board of Victoria have been holding an inquiry into certain charges laid by the matron of the Yarra Bend Hospital for the Insane against the medical superintendent, Mr W L Watkins, who had been suspended from duty pending the board's inquiry. The charges were (1) assaulting the matron and (2) want of tact and temper in carrying out his duties. The alleged assault consisted in pushing the matron out of a ward after she had refused to leave when so ordered by Mr Watkins. The evidence disclosed that the relations between the matron and the medical superintendent had not been satisfactory for some time past. The board considered the charges proved and as a punishment reduced Mr Watkins's salary from £850 to £820 a year. The board also held that the matron had been guilty of insubordination and insulting conduct and as she was over 60 years of age advised that she should be retired from the public service.

Hospital Intelligence

The annual report (the nineteenth) of the Sydney Hospital for Sick Children showed that during the past year 385 patients had been admitted, making, with the 44 remaining from the previous year, a total of 429 patients under treatment. Of this number 240 were discharged cured, 66 were relieved, 33 were discharged unrelieved, 50 died and on Dec 31st, 1898, there were 40 remaining in the hospital. 151 had been admitted to the diphtheria cottage, making, with the five remaining from the previous year, a total of 156 patients

under treatment. Of these 125 were discharged cured, 26 died, and on Dec 31st there were five remaining in the wards. There had been 10,885 attendances on 4082 out-patients. The death rate in the general hospital during the year was 9 per cent, a slight reduction on the previous year's rate of 9.88 per cent. In the diphtheria wards the death rate was 17.2 per cent, as compared with a rate of 18.78 per cent for the previous year. The Government propose to remove the Diphtheria Hospital (a sort of offshoot from the Children's Hospital) from the Glebe. It is proposed to erect a sanatorium and hospital for infectious diseases on a site of 40 acres at Kensington. A deputation from the staff of St Vincent's Hospital, Sydney, waited on the Colonial Secretary recently to ask for a grant of £2000 to build a new operating theatre. The hospital did not receive the ordinary assistance given to other hospitals. The Minister said that he was thoroughly in sympathy with the request which he would place before his colleagues. At the Sydney Hospital the following gentlemen were re-appointed to their respective positions on the honorary medical staff, viz.—Dr Jarvie Hood, physician, Dr F W Hall, assistant physician, Dr W H Goode, surgeon, Dr H L Matland, assistant surgeon, Dr Ralph Worrall, gynaecological surgeon, Dr W G Armstrong, assistant gynaecological surgeon, Mr A J Brady, aural surgeon, Dr W C Wilkinson, assistant aural surgeon, Dr Sydney Jameson, director of the pathological department, Dr Gordon MacLeod, assistant ophthalmic surgeon.

Death of Mr Maurice John O'Connor

General regret was felt when it was known that Mr Maurice J O'Connor had succumbed to an attack of pneumonia in his forty-second year. He was a native of Sydney and entered the Sydney Hospital as a surgeon's apprentice. Later he went to Dublin, where he graduated. On his return he was appointed surgeon to Darlington Gaol, which position he held until quite recently, when he was transferred to Parramatta. The deceased gentleman was for some time senior surgeon at the Sydney Hospital and representative of the staff on the Board of Directors. He was also a member of the Medical Board of New South Wales.

Presentation to Mr G A Syme

On May 4th between 70 and 80 members of the profession in Melbourne entertained Mr G A Syme, M.S., F.R.O.S. Eng., to supper and made him a presentation of an address and a piece of plate on the occasion of his approaching marriage. Mr Charles Ryan occupied the chair and spoke in flattering terms of Mr Syme's high status in the profession and the personal esteem in which he was held.

May 10th.

UNIVERSITY OF CAMBRIDGE—Mr W Chawner, Master of Emmanuel College, has been appointed Vice-Chancellor for the next academical year. Courses of instruction will be given during the Long Vacation in the departments of pathology, anatomy, and chemistry. Professor Foster and Dr D MacAlister have been appointed electors to the new chair of Agriculture. Mr A E Shipley of Christ's College has been reappointed Lecturer in the Morphology of Invertebrata. It is proposed to spend some £600 in increasing the accommodation of the new chemical laboratory for elementary students, whose numbers have increased beyond what was thought probable when it was erected and equipped some years ago. The Mathematical Tripos is rendered noteworthy this year by the appearance of a "bracket" for the senior wranglership, Birtwistle of Pembroke and Paranjpye of St John's dividing the highest honours. The latter is the first native of India to attain the distinction. Dr Donald MacAlister is appointed a member of the new Board of Agricultural Studies. At the congregation on June 8th the following medical degrees were conferred: M.D. A. P. Beddard, M.A., Trinity; G. M. Scott, B.A., Peterhouse; and F. W. Garrad, B.A., Clare. M.B. and B.C. F. A. Allfrey, B.A., Trinity; E. R. Hunt, B.A., Trinity; H. A. Gaitskell, M.A., Clare; E. P. Sewall, B.A., Pembroke; A. M. Ware, M.A., Pembroke; A. E. Carsberg, B.A., Caius; and J. F. Parker, B.A., Emmanuel. M.B. only: P. R. Lowe, B.A., Jesus; B.O. only: J. H. Kemp, B.A., Clare. Mr Timothy Holmes, M.A., F.R.O.S. Eng. and Mr Clinton T. Dent, M.A., F.R.O.S. Eng., of St George's Hospital, have in virtue of their contributions to surgery been approved for the degree of Master of Surgery.

(a) LETTER FROM THE COLLEGE OF PRECEPTORS TO THE PRESIDENT
College of Preceptors, Bloomsbury Square, London, W.C.1.

meeting in November 1957 notified that "on and after the first day of January 1959 no certificate of higher standard than that of the matriculation or entrance and the junior local examinations of the universities of the United Kingdom will be accepted for registration" and in a report of the Education Committee on which the re-join was founded the College of Physicians second-class examination (first or second division) was asserted to be of lower standard than the University junior local examinations.

that of the University Junior Local Examinations. They further proved that the Medical Council in arriving at their decision had been misled by an entirely inaccurate statement in the report of the Education Committee (November 1897) to the effect that, the Universities in the report had "indulged for students who had failed in the report of 1895 by 20 per cent."

Localities (at that time a member of the Cambridge Local Examinations) and adopted the Medical Council in November 1897.

(2) That the present standards of the College of Physicians are many respects inferior to those of the University of London, and that the present standards of the College of Surgeons are in many respects inferior to those of the University of London.

(pages 2-4) that the figures on which the accompanying Memorandum is based are absolutely incorrect, while no account whatever has been taken of the proportion of the reported candidates to the number qualified by the several examinations under consideration.

With regard to (2) it is impossible that the implied and necessary importation can have been made as it has been ascertained from the statement of the Education Committee that no inspection of Local Examinations has been made in the case of the University Local Examinations. The meaning of the expression standard desired by the "Medical Council" is not clear. If the standard is that of an examination intended for students who had at least attained the age of 16 years, then neither the college record clear nor the University Local Examinations would be desired. But if the expression "standard" is used to indicate the standard (that of the University Junior Local Examinations) then the college record would be equal to the desired standard.

With regard to (3) it is shown in the accompanying Memorandum (pages 6) that the categorical statements made by the latter of the report are contrary to fact. Further that these statements were made in face of the full details as to standards, methods, and results, which are stated in the report to have been communicated to the Education Committee.

With regard to (4) reasons are given in the Memorandum (pages 7 and 8) why but little importance should be attached to anonymous opinions solicited in the manner indicated and contrasted as they are by the fully considered and publicly expressed opinion of importance.

The Council of the college having thus pointed out the serious errors of statement and of fact which are found in the report, could hardly appeal to the President of the Medical Council to deal with the matter in such a way as will result in the practical revision of its report and of the conclusions arrived at on incorrect data. It is impossible to suppose that the Medical Council would desire even in the smallest particular to act unjustly towards another public body which has stood in responsible and friendly relation with them for more than 16 years and which has right of appeal not opportunely making use of the Council on a matter in which the representation as an examining body is equally concerned. In view of the fact that the Council of the college venture to hope that you as President of the Medical Council may find it possible to refer the question to an impartial consideration of the Council or to a committee so constituted as to ensure an impartial consideration of it.

The Council observe that in the case of professional examinations it is the custom of the Medical Council before publishing a report to submit it for remark to the examining body concerned, and they would point out that if this practice had been followed in the case of the Education Committee's reports for 1894 and 1895 the errors referred to above would have been detected before their publication.

I have the honour to be Sir your obedient servant

O. H. HODGSON Secretary

(4) ANSWER BY THE PRESIDENT

General Council of Medical Education and Registration of the United Kingdom

259 Oxford Street London W.

June 8th 1896

SIR,—Referring to your letter of April 24th, in which on behalf of the Council of the College of Physicians you protest against the conclusions arrived at in the report of the Education Committee which I would state that when the matter was brought to my notice the month ago I sanctioned the necessary correction to show that the description applied, not only to the returns from the examining boards of the medical services of the navy, army and India, but also to other examining boards. This correction was made in the report before it appeared in Volume XXXV of the Minutes.

(5) The Education Committee have called my attention to differences between the table of returns printed in your Memorandum and that drawn up by the Registrar of this Council and submitted to the committee. In your table the mode of classification adopted differs from the Registrar's and a larger number of cases are included as well as under a special heading. A number of the Registrar's table refers to 48 cases, yours to a total of 24. The Education Committee do not however admit that the method of classification adopted by your college is proper for it purports to refer to the college of all responsibility where it is granted partial certificates to defective candidates. The committee are of opinion that the inclusion of the additional cases either regarded as objectionable or unwise to any examination or which possibly may have been overlooked by the Registrar while it doubtless adds to the completeness of the table, appears to have no bearing on the point in support of which the returns were filed and does not affect the conclusions drawn from them. The committee consider that if the table of your college were taken as the basis of enumeration it would still be approved that among the examinations now on the list of the Medical Council that of your college is responsible wholly or partially for Examination one half of all the reported cases. While the Junior Local Examinations have not given rise to a single case of complaint. These were the original considerations arrived at by the committee.

Following the mode of reckoning suggested in the letter of the Dean of your college the cases of failure, total or partial, assignable to your examination are, the committee state, 16 out of over 2000. While these are assignable to the Local Examinations are none of over 4000. The comparison of percentages would thus appear to lead to the same result as that of totals.

(6) From confidential communications made by the Local Examiners and the opportunity of inquiring into the standards and methods of

marking and the conclusion came to that the requirements of the local examinations were very much higher than those of the college was not based on the opinion of an individual member of the committee but on the information submitted to the committee as a whole. The percentage of passes to rejections among candidates who presented themselves at the local examinations of the two universities in the subjects required by this Council was also before the Education Committee and in their judgment bore out the conclusion that the examination of the College of Preceptors was less stringent than those of the universities.

(d) The Education Committee have drawn my attention to the manner in which, both in the Memorandum and Statement of your college, an erroneous interpretation is put upon the expressions which the committee has employed in regard to the age standard of candidates for the Junior Local Examinations. The committee used the age of 16 as marking a well understood period of school life and stated in previous reports that the examinations they approved were such as were adapted to that age. They have also referred to a paragraph in their report of November 1896 (vol. xxiii of the Council's Minutes, p. 468) in which they divide the examinations into two groups and to another in their report of November 1897 (Minutes, vol. xxiv p. 449) in which they define their view of the status of the examinations which should be recognised as expressing their position and they hold that these paragraphs should be read together.

(e) The Education Committee point out that the suggestion that the opinion of teachers should be ascertained on the relative merits of the examinations under consideration came from the College of Preceptors. They are satisfied that the answers received in reply to Dr MacAllister's circular were fairly elicited and that they are not open to the disparaging comments made in the Memorandum. The names of the teachers and of the schools over which they preside are in the possession of the committee and the expression employed in the Memorandum that their views are the irresponsible opinions of anonymous individual schoolmasters is not justified.

(f) The Education Committee cannot admit that the College of Preceptors has established its claim to have its Junior Examination recognised as equivalent to the Junior Local Examinations or that if the College of Preceptors Second-class Examination ceases to be recognised by this Council, the Junior Locals should also be removed from the Council's list, inasmuch as no complaint regarding the scope and efficiency of the latter has been raised.

(g) I would assure the College of Preceptors that neither the Medical Council nor its Education Committee desire, even in the smallest particular to act unjustly towards the College of Preceptors in the matter of the examinations conducted by them. As regards the remark made in the last paragraph of your letter that in the case of professional examinations the Medical Council before publishing a report, submits it for observation to the examining body concerned and that it might have been well if this practice had been followed in the case of the Education Committee's reports for 1897-8 I would point out to you that the submission of the reports on professional examinations to the bodies inspected is required in Section III. 3, of the Medical Act of 1886 and that there is no provision in that Act which requires, or even suggests a similar action on the part of the Council in connexion with preliminary examinations.

(h) I may take this opportunity of stating that the Medical Council has placed at the disposal of the Education Committee a sum of money to enable that committee during the current year to obtain expert assistance in the examination of the regulations, requirements, standards, &c. as well as the answers and markings of candidates of the several preliminary examinations.

I would further call your attention to the statement in the closing paragraph of the Education Committee's Report of 1898, that should the authorities of the College of Preceptors see fit to establish a Preliminary Examination of a standard equal or superior to that of the other Junior Examinations recognised by the Council, the committee would be prepared to include such an improved examination in the List.

I am, Sir, yours faithfully,

WILLIAM TURNER,

President of the General Medical Council.

C. R. Hodgson Esq

Election of the Executive Committee

The following members were elected by ballot to form the Executive Committee—viz Sir Dyce Duckworth, Mr Bryant, Mr Carter, and Dr Glover for England, Dr Heron Watson and Sir William Gardner for Scotland, and Dr Athhill and Sir Philip Smyly for Ireland. In announcing the result of the ballot the President explained that all the old members had been re-elected.

The Pharmacopœia

Dr LEECH brought up the following report from the Pharmacopœia Committee, viz—

The Pharmacopœia Committee beg leave to report that 26,500 copies of the British Pharmacopœia of 1898 have been printed and 25,225 of these have passed into circulation, leaving in hand only 1275 copies; it is therefore evident that at an early date a further re-issue will be needed.

The Pharmacopœia Committee note with satisfaction that the Legislatures of Queensland and of Victoria have sanctioned Acts which provide for the adoption of the British Pharmacopœia in Queensland and Victoria respectively.

In accordance with the report of the Pharmacopœia Committee adopted by the Council in November 1893 the Pharmaceutical Societies of Great Britain and Ireland were invited to appoint representatives to confer with the members of the Pharmacopœia Committee and nominated Mr C. Ekin Dr W. Inglis Clark and Mr R. J. Downes to act in this capacity. A conference has been held at which Dr Leech Dr MacAllister and Dr Tizard (secretary) met the above-named representatives and discussed numerous points connected with subjects dealt with in the Pharmacopœia.

It is recommended that the Pharmacopœia Committee be allowed to authorise the publication of reports received from experts in pharmacy

and pharmaceutical chemistry upon matters deemed worthy of investigation.

The President has addressed a letter to the Lord President of the Privy Council requesting that a report upon the Indian and Colonial Addendum should be forwarded through the Privy Council to the Indian and Colonial Authorities. Communications have been received from the India Office and from the Colonial Office expressing readiness to comply with this request.

The report has been widely circulated copies having been sent to about 900 medical and pharmaceutical authorities and experts in India and the British Colonies.

Valuable criticisms and suggestions have already been received from some of the Indian and colonial medical authorities and also from Surgeon General G. Bidle (Retd.).

A comprehensive committee has been formed in Canada to consider what additions it is desirable to make to the Addendum in order to adapt the Pharmacopœia to the requirements of the Dominion and a preliminary report has already been received from this body.

After the various communications have been considered by the Pharmacopœia Committee a draft Indian and Colonial Addendum will be drawn up and submitted for the approval of the Council. But much time must elapse before all the comments can be received and considered and it will probably be found impossible to present the draft Addendum at the November meeting of the Council.

Dr LEECH, in moving the adoption of the report, said it would be seen that the circulation of the Pharmacopœia was going on in a very satisfactory manner, and he thought the Council was to be congratulated on the fact that the work would be at least no burden on the funds of the Council. There was only one point to which he desired to call attention. The committee had submitted certain questions to experts and they desired to have power to publish their replies without necessarily coming to the Council for sanction. It was considered that there would be considerable advantage in having the replies published at once instead of waiting for another meeting of the Council. He might add that none of the property of the committee was destroyed in the fire at Messrs Spottiswoode's.

The report was at once adopted.

The Finances of the Council

The following report by the Finance Committee was received and entered in the minutes, viz—

The Finance Committee report that the income of the General and Branch Councils for the year ending Dec. 31st, 1898, was £14,629 3s. 3d. and the expenditure for the same period having been £13,905 10s. 2d., there is a surplus of £723 13s. 1d. From Table A it will be seen that this is chiefly due to the publication of the new Pharmacopœia. From the same table it will also be seen that the fees received by the branch councils again show a slight decrease, for £273 5s. less was received from that source in England and £13 2s. 6d. less in Ireland, while Scotland shows an increase of £172 2s. 6d., the total decrease therefore being £114 5s. These figures would seem to show that though the fees will probably continue to decrease slightly each year owing to the increasing stringency of the conditions of qualification, yet the effect of the introduction of the five years' rule has now passed, for the decrease in fees in 1897 was £779 12s. 6d.

The items of increased expenditure are shown on Table B and amongst these may be specified the following—

(a) An increase of £1214 8s. 2d. for General Council fees and of £122 4s. 8d. for Executive Committee fees, occasioned by the extra session of the Council and the length of its meetings. The Executive Committee also met in July whereas last year (1897) it did not meet between the May and November sessions.

(b) An increase of £2454 18s. 2d. for the British Pharmacopœia, due to the cost of publishing the new work.

(c) An increase of £171 15s. 11d. in the cost of printing the Medical and Students Registers regarding which the Stationery Office writes: "This is the first supply under a new contract, and the charge is higher than usual on account of this office having to pay full printing composition rates. During the currency however, of the new contract the charge for future editions will be considerably lower."

(d) An increase of £223 6s. in the inspection of examinations owing to the scheme regarding the Apothecaries Hall, Ireland, having come into force.

(e) An increase of £138 2s. 7d. in miscellaneous expenses occasioned chiefly by the issue of the circular regarding the employment of unqualified assistants and partly also by the extra session of the Council.

On the other hand decreased expenditure has to be noted:—

(a) In salaries, £601 10s. 1d.

(b) In law expenses, £133 17s. 11d.

Table C shows that the average yearly expenditure of the General and Branch Councils for the past seven years has exceeded the average yearly income by £310 13s.

The "percentage rate" which shows what part of the money received by the several branch councils has, pursuant to Section 13 of the Medical Act, 1893, been paid towards defraying the General Council's expenses was considerably lower during the past year having been 71.69 as against 109.89 in 1897, caused by the receipts having been increased by the refunding of the money expended on the British Pharmacopœia in the last few years. The auditor recommends that in future the money spent in the preparation of a Pharmacopœia should not be charged as part of the expenditure of the year but should be carried forward until the book is published. The violent fluctuations of receipts and expenditure which now take place would thus be avoided and a comparison of the figures, year by year, would be more simple.

With regard to the current year all the items of increased expenditure may reasonably be expected to show a decrease save of them to a considerable extent with the exception of the inspection of examinations (the Apothecaries Hall, Dublin) and the interest payable on the mortgage.

The latter item will be increased on account of the additions to the

 English Branch Council. It probably causes an additional annual ex-
 pending Fund for which a sum not exceeding £3000 is allowed—and the
 building—For which has been approved of to pay off the debt to the

THE ENGLISH BRANCH COUNCIL have advanced to the General Medical Council the sum of £25,000 for the purchase of a freehold and the erection of a building. That sum, accordingly, is to be repaid at the end of the term of years and I am requested to advise as to methods of such repayment. I propose that the General Medical Council pays the English Branch the sum of £50 per annum as interest. Repayment may be effected in any one of three ways:—
1. By an annuity arranged between the General Medical Council and the English Branch Council without the intervention of a third party.
2. An annuity of £371 12s. 9d. (being only £221 12s. 9d. more than the amount now payable for interest alone) paid by the General Medical Council to the English Branch Council at the end of each year for fifty years. Under this arrangement the debt will be 3 per cent. interest, and as the outstanding balance of the debt is £25,000, the interest is £750, which is a considerable sum, but a small amount is available in repayment of principal, but as time goes on the instalments of interest and the instalments of principal will be required to discharge the debt being treated by the English Branch Council as income. We are the principal to be inadequately repaid as income at the end of 50 years and £25,000 had vanished.
3. An annuity by annual premiums.
An annuity company in consideration of a premium of £215 12s. 6d. payable at the beginning of each year for 50 years, will guarantee the payment of the sum of £25,000 at the end of 50 years. (The Alliance Company being suggested.)
4. If the plan now complicated bookkeeping would be required because the debt would be repaid by means of the policy in a lump sum at the end of the 50 years.
5. An annuity by single premium.
An assurance company in consideration of a single premium at the rate of £22 18s. 2d. per cent. will guarantee the repayment of a sum of £25,000 at the end of 50 years.
Under this plan the sum to be assured would be £32,388 13s. 4d. so as to provide for the repayment of the premium as well as the debt. The English Branch Council would have to advance the single premium of £32,388 13s. 4d. in addition to the £25,000, bringing up the debt to £57,388 13s. 4d. on which the General Medical Council would have to pay interest for 50 years—a much better return than a 3 per cent. compound interest is found for the £32,388 13s. 4d. The simplest and most recommended investment is in the Imperial War Loan, which required this plan seems the best. Now only a sum of £37,388 13s. 4d. would be required.
If the English Branch Council can conveniently and the additional sum of £37,388 13s. 4d. be paid in the form of a falling rate of interest this is an advantage not to be despised.
7. Royal Exchange, London E.C. 4 April 5th, 1893.
W. BRYANT moved, Sir DICEY DUCKWORTH seconded, and it was agreed to —
That, in accordance with the recommendation of the auditor the money spent in the preparation of the British Pharmacopœia should be kept as a separate account.

Mr. BRYANT moved —
That the treasurer be requested to carry out the resolution of the Council as to the formation of a sinking fund by the adoption of the compound method mentioned in the report of the London Assurance Corporation—viz. the payment of an annual premium of £215 12s. 6d. for a period of 50 years.
Mr. Bryant explained that the committee had come to the conclusion that it would not be expedient to diminish the capital of the Council, which at present amounted to about £12,000, by so large a sum as £7388.
Mr. DUCKWORTH seconded the motion and it was agreed to.
Mr. BRYANT, in reference to the drop in the assets of the Irish Branch Council from £801 18s. 5d. in 1896 to £284 9s. 10d. in 1898, moved
That the question of the financial condition of the Irish Branch Council be referred for consideration to the General Council (with power to take legal advice) and report to the General Council.
The PRESIDENT asked if any of the Irish representatives could explain the extraordinary drop in their assets of £517 in two years.
Mr. LOMBE AITHELL said that the receipts of the Irish Branch Council last year and the year before had not been so good as formerly, owing, he thought, to a considerable percentage of Irish students going to Scotland to obtain their degrees. He had been a member of the General Medical Council for a good many years and when he first entered it the Irish Branch Council had as much as £1000 at its credit, but expenses had been so heavy and the revenue had so increased that that balance had almost disappeared, and the present day had a balance of only some £200. The General Medical Council might take it that so soon as they got a little money together they would remit, for it was their desire to be as honest as poor men could be. They certainly would pay every shilling that they could.
Sir CHRISTOPHER NIXON said that perhaps properly the Irish Branch Council was represented as an impetuous body, but in answer to the President's question as to why they were in this distress he must say that it was the history of what usually took place when there were any analogous relations between England and Ireland. He should venture to suggest that the question should be dealt with by the amendments of the Medical Acts.
Sir FRANK BAILEY pointed out that the Irish Branch Council had no power of increasing its income from registration, but he did not believe that the revenue of that Council would diminish very much more. On the contrary, he hoped—and he did not think it was a hope without some good ground—that the funds of the Irish Branch Council would increase.
Sir DYCE DUCKWORTH thought that the history of the Council during the last 16 years explained the expenditure. What he wanted to know was why such a large number of Irish students should go to Scotland to seek a diploma.
Sir CHRISTOPHER NIXON. The education is cheaper and the examinations are easier to pass.
Dr. McVAIL said that that was not so.
Mr. BRYANT next moved
That the other portions of the Finance Report be approved and adopted.
The recommendation was adopted.
The motion was agreed to and the report of the Finance Committee, with its several recommendations was passed.
The Penal Cases Committee
The PRESIDENT announced that the result of the ballot for the election of the Penal Cases Committee was that the four representatives for England were Mr. Bryant, Mr. Brudenell Carter, Dr. Glover, and Mr. Horsley, and that the two Scotch representatives were Dr. Heron Watson and Dr. Bruce Thomson was distinguished elected, but there was a tie in the voting as respects Dr. Lombé Aithell and Sir Christopher Nixon.
Sir LOMBE AITHELL. I wish that Sir Christopher Nixon should be the member of this committee.
Sir CHRISTOPHER NIXON. I should like that Dr. Aithell would undertake the duty.

marking and the conclusion come to that the requirements of the local examinations were very much higher than those of the college was not based on the opinion of an individual member of the committee but on the information submitted to the committee as a whole. The percentage of passes to rejections among candidates who presented themselves at the local examinations of the two universities in the subjects required by this Council was also before the Education Committee and in their judgment bore out the conclusion that the examination of the College of Preceptors was less stringent than those of the universities.

(d) The Education Committee have drawn my attention to the manner in which, both in the 'Memorandum' and Statement of your college, an erroneous interpretation is put upon the expressions which the committee has employed in regard to the age standard of candidates for the Junior Local Examinations. The committee used the age of 16 as marking a well understood period of school life and stated in previous reports that the examinations they approved were such as were adapted to that age. They have also referred to a paragraph in their report of November 1896 (vol. xxxiii. of the Council's Minutes, p. 468) in which they divide the examinations into two groups and to another in their report of November 1897 (Minutes, vol. xxxiv. p. 449), in which they define their view of the status of the examinations which should be recognised as expressing their position and they hold that these paragraphs should be read together.

(e) The Education Committee point out that the suggestion that the opinion of teachers should be ascertained on the relative merits of the examinations under consideration came from the College of Preceptors. They are satisfied that the answers received in reply to Dr MacAlister's circular were fairly elicited and that they are not open to the disparaging comments made in the Memorandum. The names of the teachers and of the schools over which they preside are in the possession of the committee and the expression employed in the Memorandum that their views are the 'irresponsible opinions of anonymous individual schoolmasters' is not justified.

(f) The Education Committee cannot admit that the College of Preceptors has established its claim to have its Junior Examination recognised as equivalent to the Junior Local Examinations or that if the College of Preceptors Second-class Examination ceases to be recognised by this Council, the Junior Locals should also be removed from the Council's list, inasmuch as no complaint regarding the scope and efficiency of the latter has been raised.

(g) I would assure the College of Preceptors that neither the Medical Council nor its Education Committee desire, even in the smallest particular, to act unjustly towards the College of Preceptors in the matter of the examinations conducted by them. As regards the remark made in the last paragraph of your letter that in the case of professional examinations the Medical Council before publishing a report, submits it for observation to the examining body concerned and that it might have been well if this practice had been followed in the case of the Education Committee's reports for 1897-8 I would point out to you that the submission of the reports on professional examinations to the bodies inspected is required in Section III. 3, of the Medical Act of 1886 and that there is no provision in that Act which requires, or even suggests a similar action on the part of the Council in connexion with preliminary examinations.

(h) I may take this opportunity of stating that the Medical Council has placed at the disposal of the Education Committee a sum of money to enable that committee during the current year to obtain expert assistance in the examination of the regulations, requirements, standards, &c. as well as the answers and markings of candidates of the several preliminary examinations.

I would further call your attention to the statement in the closing paragraph of the Education Committee's Report of 1898, that should the authorities of the College of Preceptors see fit to establish a Preliminary Examination of a standard equal or superior to that of the other Junior Examinations recognised by the Council, the committee would be prepared to include such an improved examination in the List.

I am, Sirs, yours faithfully,

WILLIAM TURNER,
President of the General Medical Council

C. R. Hodgson Esq

Election of the Executive Committee

The following members were elected by ballot to form the Executive Committee—viz Sir Dyce Duckworth, Mr Bryant, Mr Carter, and Dr Glover for England, Dr Heron Watson and Sir William Gardner for Scotland, and Dr Atthill and Sir Philip Smyly for Ireland. In announcing the result of the ballot the President explained that all the old members had been re-elected.

The Pharmacopœia

Dr LEECH brought up the following report from the Pharmacopœia Committee, viz—

The Pharmacopœia Committee beg leave to report that 25,500 copies of the British Pharmacopœia of 1898 have been printed and 25,225 of these have passed into circulation, leaving in hand only 1275 copies. It is therefore evident that at an early date a further re-issue will be needed.

The Pharmacopœia Committee note with satisfaction that the Legislatures of Queensland and of Victoria have sanctioned Acts which provide for the adoption of the British Pharmacopœia in Queensland and Victoria respectively.

In accordance with the report of the Pharmacopœia Committee adopted by the Council in November 1893 the Pharmaceutical Societies of Great Britain and Ireland were invited to appoint representatives to confer with the members of the Pharmacopœia Committee and nominated Mr O. Ekin, Dr W. Inglis Clark and Mr R. J. Downes to act in this capacity. A conference has been held at which Dr Leech, Dr MacAlister and Dr Tirard (secretary) met the above-named representatives and discussed numerous points connected with subjects dealt with in the Pharmacopœia.

It is recommended that the Pharmacopœia Committee be allowed to authorise the publication of reports received from experts in pharmacy

and pharmaceutical chemistry upon matters deemed worthy of investigation.

The President has addressed a letter to the Lord President of the Privy Council requesting that a report upon the Indian and Colonial Addendum should be forwarded through the Privy Council to the Indian and Colonial Authorities. Communications have been received from the Indian Office and from the Colonial Office expressing readiness to comply with this request.

The report has been widely circulated copies having been sent to about 900 medical and pharmaceutical authorities and experts in India and the British colonies.

Valuable criticisms and suggestions have already been received from some of the Indian and Colonial medical authorities and also from Surgeon General G. Billie (Retd.).

A comprehensive committee has been formed in Canada to consider what additions it is desirable to make to the Addendum in order to adapt the Pharmacopœia to the requirements of the Dominion and a preliminary report has already been received from this body.

After the various communications have been considered by the Pharmacopœia Committee a draft Indian and Colonial Addendum will be drawn up and submitted for the approval of the Council. But much time must elapse before all the comments can be received and considered and it will probably be found impossible to present the draft Addendum at the November meeting of the Council.

Dr LEECH, in moving the adoption of the report, said it would be seen that the circulation of the Pharmacopœia was going on in a very satisfactory manner, and he thought the Council was to be congratulated on the fact that the work would be at least no burden on the funds of the Council. There was only one point to which he desired to call attention. The committee had submitted certain questions to experts and they desired to have power to publish their replies without necessarily coming to the Council for sanction. It was considered that there would be considerable advantage in having the replies published at once instead of waiting for another meeting of the Council. He might add that none of the property of the committee was destroyed in the fire at Messrs Spottiswoode's.

The report was at once adopted.

The Finances of the Council

The following report by the Finance Committee was received and entered in the minutes, viz—

The Finance Committee report that the income of the General and Branch Councils for the year ending Dec. 31st 1898, was £14,629 3s. 3d., and the expenditure for the same period having been £13,905 10s. 2d., there is a surplus of £723 13s. 1d. From Table A it will be seen that this is chiefly due to the publication of the new Pharmacopœia. From the same table it will also be seen that the fees received by the branch councils again show a slight decrease, for £273 5s. 11d. was received from that source in England and £13 2s. 6d. less in Ireland, while Scotland shows an increase of £172 2s. 6d., the total decrease therefore being £114 5s. These figures would seem to show that though the fees will probably continue to decrease slightly each year owing to the increasing stringency of the conditions of qualification, yet the effect of the introduction of the five years' rule has now passed, for the decrease in fees in 1897 was £779 12s. 6d.

The items of increased expenditure are shown on Table B and amongst these may be specified the following:—

(a) An increase of £1214 8s. 2d. for General Council fees and of £122 4s. 8d. for Executive Committee fees, occasioned by the extra session of the Council and the length of its meetings. The Executive Committee also met in July whereas last year (1897) it did not meet between the May and November sessions.

(b) An increase of £2454 18s. 2d. for the British Pharmacopœia, due to the cost of publishing the new work.

(c) An increase of £171 15s. 11d. in the cost of printing the Medical and Students' Registers regarding which the Stationery Office writes: 'This is the first supply under a new contract, and the charge is higher than usual on account of this office having to pay full printing composition rates. During the currency however of the new contract the charge for future editions will be considerably lower.'

(d) An increase of £223 6s. in the inspection of examinations owing to the scheme regarding the Apothecaries Hall, Ireland, having come into force.

(e) An increase of £138 2s. 7d. in miscellaneous expenses occasioned chiefly by the issue of the circular regarding the employment of unqualified assistants and partly also by the extra session of the Council.

On the other hand decreased expenditure has to be noted:—

(a) In salaries, £601 10s. 1d.

(b) In law expenses, £133 17s. 11d.

Table C shows that the average yearly expenditure of the General and Branch Councils for the past seven years has exceeded the average yearly income by £310 13s.

The 'percentage rate' which shows what part of the 'money' received by the several branch councils has, pursuant to Section 13 of the Medical Act, 1853, been paid towards defraying the General Council's expenses was considerably lower during the past year having been 71.69 as against 109.89 in 1897, caused by the receipts having been increased by the refunding of the money expended on the British Pharmacopœia in the last few years. The auditor recommends that in future the money spent in the preparation of a Pharmacopœia should not be charged as part of the expenditure of the year but should be carried forward until the book is published, the violent fluctuations of receipts and expenditure which now take place would thus be avoided and a comparison of the figures, year by year, would be more simple.

With regard to the current year all the items of increased expenditure may reasonably be expected to show a decrease some of them to a considerable extent, with the exception of the inspection of Examinations (the Apothecaries Hall, Dublin), and the interest payable on the mortgage.

The latter item will be increased on account of the additions to the

The PRESIDENT As Dr Athill spoke first, Sir Christopher, I shall add your name to the committee

The committee accordingly is composed as follows for England—Mr Bryant, Mr Carter, Dr Glover and Mr Horsley, for Scotland—Dr Heron Watson and Dr Bruce, for Ireland—Sir William Thomson and Sir Christopher Nixon

Students' Registration Committee

Sir DYCE DUCKWORTH submitted a report from the Students' Registration Committee on exceptional cases which they had considered and dealt with. He moved that the report be entered on the minutes

Dr MACALISTER seconded the motion, which was agreed to

Reciprocity of Medical Practice

The Council resumed the consideration of communications from the Privy Council Office in regard to the practice of Italian medical practitioners in this country and the question of reciprocity in regard to which the General Medical Council on May 31st, 1899, resolved—

That it be remitted to Mr Muir Mackenzie to advise the Council as to whether, under Section 17 of the Medical Act of 1886, the privileges to foreign practitioners can be restricted to the recognition of practice by them amongst their fellow-countrymen only who may be resident in this country

On this subject the following opinion has now been received—

The question on which as I understand, my advice is asked is whether under Section 17 of the Medical Act, 1886, the privileges accorded to foreign practitioners under Part 2 of the Medical Act, 1886, can be restricted to the recognition of practice by them amongst their fellow-countrymen only who may be resident in this country

The 17th Section of the Medical Act, 1886, provides, as regards a foreign country that Her Majesty may by Order in Council declare that Part 2 of the Act shall be deemed on and after a day to be named in the Order (which in the Act is called the prescribed day) to apply to a foreign country which in the opinion of Her Majesty affords to the registered medical practitioners of the United Kingdom such privileges of practising in the foreign country as to Her Majesty seem just.

The effect of the section is that on such an Order being made by Her Majesty Part 2 of the Act becomes applicable to the practitioners of the foreign country

The effect of the application of Part 2 of the Act to the foreign country is that by Section 12 of the Act a person who satisfies the Registrar that he holds a recognised medical diploma of the foreign country and satisfies the other conditions contained in Section 12 is entitled to be registered in the list of foreign practitioners in the Medical Register

The effect of Sections 6 and 14 of the Medical Act of 1886 is that every person who becomes registered as a foreign practitioner becomes entitled to practise medicine, surgery, and midwifery in the United Kingdom and British Dominions.

There is no express provision in Section 17 or in any other provision of the Medical Act, 1886, which empowers Her Majesty by the Order in Council which applies the Act to a foreign State, to limit the right of the foreign practitioners who by virtue of the Order in Council and the Act become entitled to be registered.

In the absence of any express power to impose such a restriction as is suggested by the question put to me my opinion is that no such restriction could be imposed by an Order in Council made under Section 17.

If Her Majesty is advised that a foreign country affords to the registered practitioners of the United Kingdom such privileges of practice as Her Majesty thinks just, Her Majesty can make an Order applying Part 2 of the Act to that foreign country but upon such an Order being made the practitioners of the foreign country who satisfy the requirements of the Act will be entitled to the full privileges which the Act confers.

My opinion, therefore to the question submitted to me is that the privileges to foreign practitioners cannot be restricted in the manner indicated in the question.

M. MUIR MACKENZIE.

4, Temple-gardens, B.C. June 7th 1899

As Mr Muir Mackenzie was not in attendance Dr MOVAIL moved that the case should not go on. He did not think it was right to proceed while Mr Muir Mackenzie was absent. It was quite unfair to Mr Muir Mackenzie to go into the case in his absence as it was also unfair to any public interest involved.

Dr HECTOR CAMERON agreed

Dr GLOVER refused to adjourn consideration of the case on the ground put forward. If Mr Mackenzie was not present that was his misfortune, not his fault.

On a division five members voted for the motion proposed by Dr MOVAIL and 11 against it.

The motion was rejected and the opinion of Mr Muir Mackenzie was entered on the minutes.

The Case of the late Mr H. K. Hunter

Mr HORSLEY asked leave to draw attention to the proceedings taken in the name of the Council against the late Mr H. K. Hunter.

A narrative, extending to 43 pages of 8vo print drawn up by direction of the President for the information of members of the Council, was circulated.

The PRESIDENT moved that this narrative be received and entered on the minutes and that no other name but that of Mr Hunter be mentioned therein.

This motion was carried.

The PRESIDENT then said that his wish had been to give a correct narrative of the case and that perhaps accounted for the somewhat unusual dimensions to which the print had gone.

Mr HORSLEY said that his object in drawing attention to this case was to exculpate the General Medical Council from the charges which had been made against it outside the four walls of their chamber to the effect that they had prosecuted a registered medical practitioner for calling himself a physician. He went on to say that the Council had not, as they viewed the case, prosecuted a registered medical practitioner but a man whom they were given to understand was an unregistered medical practitioner, using a bogus American M.D. degree.

Mr BROWN believed that the members of the General Medical Council were not aware of the full facts of the case when the proceedings were taken against Mr Hunter. He certainly was of opinion that it should be recorded that the prosecution of Mr Hunter was not sanctioned by the Council in its capacity of a Council.

Dr GLOVER, as a member of the Penal Cases Committee as well as a member of the General Medical Council, wished to express his belief that if this case had not been made a test case more assistance would have been given to Mrs. Hunter and he hoped that the fund which was being raised for her would be largely augmented.

After some discussion Dr GLOVER said that the case had been proceeded with in a friendly spirit and without any animus. It was a test case and not a personal one.

The PRESIDENT defended Mr Muir Mackenzie's action. The subject dropped.

Reciprocity of Medical Practice

On Dr MACALISTER rising to move the ninth order on the paper,

Dr MOVAIL said: What about the eighth order? (Mr Muir Mackenzie's opinion on reciprocity with the practitioners of Italy.)

Dr MACALISTER said that that opinion had already been entered on the minutes and he now proposed that the Executive Committee should consider it along with the memorandum on reciprocity.

Mr BRYANT seconded.

Dr MOVAIL said that he was not satisfied with that explanation of the subject. Now that they had got Mr Muir Mackenzie's opinion he did not see that they could go on either to a discussion or division on the subject.

Dr MACALISTER said it was impossible for the United States of America to enter into reciprocity and as a matter of fact it was impossible for Canada to enter into a reciprocity.

The Council adjourned.

FRIDAY, JUNE 9TH

The Council held its final sitting to-day when there was a very much reduced attendance of members. Sir WILLIAM TURNER occupied the chair.

Reciprocity of Medical Practice

The Council proceeded with the consideration of the following motion by Dr MACALISTER, seconded by Mr BRYANT—

That the opinion of Mr Muir Mackenzie in regard to the following resolution, adopted by the General Council on June 8th 1899—

That it be remitted to Mr Muir Mackenzie to advise the Council as to whether, under Section 17 of the Medical Act of 1886, the privileges to foreign practitioners can be restricted to the recognition of practice by them amongst their fellow-countrymen only who may be resident in this country—be referred to the Executive Committee for consideration in connexion with the memorandum on reciprocity.

Dr MOVAIL asked the President if he had any information as to whether the Privy Council had taken any action in consequence of the letter sent to the Privy Council by the Executive Committee regarding recognition of Italian medical graduates in this country.

The PRESIDENT replied that the information he had was that the Privy Council had as yet not taken any action. Obviously the Privy Council had waited until the meeting of the Council.

Dr MOVAIL then moved a long motion, the effect of which was that it be remitted to the Executive Committee to represent to the Privy Council that in reply to the question put by the Council Mr Muir Mackenzie gave the

was set forth in the minutes and that the Executive Committee be requested in a covering letter to the Privy Council to indicate the difficulties which surround the granting or recognition to medical graduates of foreign countries or whose countries of study and professional examinations the General Medical Council can exercise no supervision, and that in the event of any further official communications bearing on the subject being received the Executive Committee be requested to consider whether the principle of a limited recognition or prize is already established by Section 6 of the Act of 1859 might not be extended by a short enactment. Dr McVail explained that the extension in his mind was that of allowing Italian practitioners to attend Italian students in this country. What had been asked by British practitioners had been the privilege of attending British residents in Italy.

Mr. DONALD CARVER, president of the National Association of Manufacturers, said that the motion should stop at the word "appeal," because the President of the Privy Council had told them that he would not contemplate a store enactment of this kind, but only a general amendment concerning the whole subject.

Dr. MCALVA said he was quite prepared to accept this suggestion.

Dr. GLOVER thought the Council should indicate to the

Dr Hector CAMERO pointed out that British medical men practising in Italy had a large number of American students, and that the probability they would not be concerned with recognition of practice among British students— they would probably wish to extend it to English students.

Dr MACALISTER said he was strongly impressed with the idea that unless they had proper inspection of the whole machinery of education and examination they should not give recognition in this country. Of course, if the Privy Council chose to recognise foreign or colonial diplomas without the advice of the Council the responsibility would lie with the Privy Council.

Dr MACALISTER said he was anxious that the Privy Council should not think the Council were inconsistent and as a matter of fact the Council were recognising these diplomas—they were doing it every day by putting people on the Colonial Register.

After some further discussion the motion with all the words at or "supersession" deleted was agreed to.

The Midwives Question
The REGISTRAR (Mr Allen) read the following communication from the Privy Council Office in answer to a communication from the President of the General Medical Council forwarding a draft report adopted by the Midwives Bill Conference Committee —

The Clerk of the Council,
Privy Council Office, London, S.W.,
June 6th, 1939.

Sir—According to your letter of April 10th sent on the subject of the suggested Bill now before Parliament I am directed by the Lord President to inform you that in the result of further communication with the promoters of the Bill they are willing to meet the views expressed in the 4th paragraph of the report of the committee of the General Medical Council by the addition to Clause 3 (2) of the words "a community or disease in connection with partition." I would cases or, as the Bill is referred under the Medical Acts to "lead cases or diseases" is preferred to the change in the definition of malpractice which is also in Clause 2 of the Bill is merely a description, and would avoid any doubt as to the meaning of the word "community."

I am to add that this concern seems sufficient to meet the needs of the country, and that in respect to almost all the other points mentioned in your committee's report the promoters of the Bill are in agreement with the suggestions that have been made by it. It is interesting to see the Lord President did not see any need to present and discuss the proposals of the committee relative to the Board of the Minorities.

I am, Sir your obedient servant,
 Wm. James P.R.S.
 President of the General Medical Council.

It would be very much better to take a genuine working on the part of the midwife to attend any case or abnormal labour or any case of disease in connection with parturition and this letter said "His Grace is advised that, as a matter of fact, this form of amendment is preferable to the change in the definition of midwife which found favour with your committee." He showed this letter to every member of the committee and they agreed that it would be better to accept the decision of the Privy Council in the matter, because, after all, it was a matter of the drafting of the Bill, and the Privy Council had access to the Government draftsman, and the President agreed that they should accept the opinion of the Privy Council as to the best way of stating the law. This was to have come forward yesterday, but owing to the large amount of business to be performed the President last night drafted a letter expressing the view of the committee, which was to accept the opinion of the Privy Council in the matter, and that letter had actually been sent to the Privy Council Office. In the name of the Council the President had accepted the judgment of the Privy Council. Just one alteration had been suggested. It was pointed out that the term "abnormality" often carried a technical sense and it was suggested that the words should run that midwives should be prohibited from "attending cases of abnormal labour." The terms of the President's letter were read to the Council.

Mr. Brown said he desired to take the opportunity of saying that he did not approve of any legislation of this kind for midwives.

Dental Penal Cases.

The recommendation from the Local Committee as to adopting a new Standing Order for regulating procedure in penal cases was brought up again and adopted by the Council

DR GLOVER moved
That a committee of the General Medical Council be appointed to consider necessary amendments of the Medical Acts.

He said that among subjects calling for attention were the unacceptability of restoration to the Registrar, the inequality of the powers of the bodies in the matter of dealing with their graduates and licentiates, the amendment of Section 40 of the Act, the inspection of the examinations for the higher qualifications, the question of reciprocity (for which, he said, some solution must be found, because at this time of day it was impossible to deny reciprocity) between nations in respect of equally educated men, and the question of the constitution of the Council itself. He could not help thinking that they had had sufficiently long relations with the present Government to have borne in upon them the conviction that they were a very moderate and reasonable set of men and that any proposals they might make to them were entitled to their best and most earnest consideration.

ST WILLIAM THORSON in the absence of Dr Bruce

seconded the motion
SIR CHRISTOPHER NIXON said he cordially supported the motion. For his part he would like to see the law declare that no one should be allowed to practise unless he had been registered. Another point he would like to see attention given to was the financial position of the Council, and another was the right to use medical titles.

SIR JOHN BARRY DUKE said that from the point of view of the Education Committee it would be desirable to have an amendment of the law with regard to the registration of students. It was specially laid down in the Act that the Council should obtain information as to the ages at which certain courses of study and examination took place and the Council had no machinery for the purpose except what they had constructed for themselves. It seemed to him that they should be able to carry out the duties of the Act as it stood at present by the establishing of a right to register students and to determine the conditions under which they were to be registered.

The PRESIDENT said he would like to call the attention of the Council to the interim reports which he had issued as to the disciplinary powers and efforts to get the various medical authorities into line and to agree to an Act which would carry out certain very important amendments and would give powers to the bodies to do what many of them could not do at present—namely, cancel or revoke the diplomas they had conferred.

Although in the first stage of the negotiations various objections had been raised, he hoped

that in the second stage the bodies would all come into line. Another point in this connexion was the disposition of the penalties paid in the metropolitan police districts. If he could get these agreed to and carried undoubtedly important reforms would be instituted, but from what had fallen from various speakers in this debate it seemed to him that the intention was to get, not a reform of the existing Act, but a new Medical Act, altogether. Of course, if the Council were of opinion that the report of such a committee as was proposed would enable them to get that he made no objection but he had grave doubts whether it would enable them. He ventured to make the suggestion that they should not be precipitate in this matter let them wait until next November and see what answers the bodies gave to him upon the clauses which would be sent to them. He felt sure that a little delay would not be disadvantageous.

Dr MACALISTER said there was a consideration against this roving commission that the Council were an administrative and judicial body, and if they began from within to propose practically the reconstruction of the Act under which their powers were given they must immensely weaken what they did under the existing law, and the moral effect of their action would be vastly weakened. He thought that amendments of the Medical Acts would come far better from outside bodies and what they proposed would surely come before the Council for their consideration and approval. If the Council initiated legislation in a general and whole sale way he was sure that the Privy Council would adopt a different attitude from that which they had, so to speak, succeeded in winning from them and he was afraid it would undermine their power.

Mr BROWN said that his view was that from no quarter could legislative proposals come more appropriately than from the Council which from long experience of their working knew well the shortcomings of the existing Medical Acts, and he would point out to the President that unless they were ready with a Bill in November next they could not expect an Act in 1900.

The PRESIDENT. You may add a good many years to that, Mr BROWN.

Mr CARTER said that the proper people to introduce amendments to the Medical Acts were members of the legislature and they had the advantage of having in the House of Commons members of their own profession—men of great attainments, accustomed to deal with public affairs, and men of sound sense and discretion. If members of the profession were anxious to reform the Medical Acts their first step should be to approach these gentlemen and to endeavour to enlist their assistance in the undertaking. Any Bill that these gentlemen might be induced to promote or back would unquestionably be referred to the Council and he had no doubt that the supporters of the Bill would value the advice they might be able to give them, but for the Council to engage in a perfectly indefinite inquiry as to what some people thought necessary and other people might think exceedingly unnecessary would be in his opinion a wasting of time.

Dr GLOVER, replying on the debate, pointed out that the hands of the Council would not be tied by anything the proposed committee might report, because it would always be open to the Council to reject the report or any part of it to which they took exception. It was a most astounding doctrine which Mr Carter had laid down that the persons to bring about, to carry through, and to ask for the amendment of the Medical Acts were the three or four medical men who happened to be members of the House of Commons. As regards one or two of these gentlemen he had heard it stated in the House of Commons that they had sunk the doctor in the politician, but surely Mr Carter did not seriously mean that they were to depend for important legislation of this kind upon certain medical men who chanced to be members of the House of Commons.

A vote was then taken, when eight voted for the motion, 10 voted against it, three members did not vote, and nine members were absent. The motion was accordingly lost.

Dr MCVAIL said that the result of the voting showed how wrong it was to take a motion of this kind upon the last day of a long session. It ought to have been taken early in the session and a considerable part of a day given to its discussion.

The Council and the Profession

Mr HORSLEY moved —

That all memorials addressed to the General Medical Council be received and laid upon the table.

He thought that if the Council's procedure was in accordance with what he proposed nobody would have any cause of complaint.

Dr MACALISTER and the PRESIDENT pointed out that any memorials sent to the General Medical Council required in the first instance to be inspected by the Business Committee or the Executive Committee and that if they were of a suitable character they might then proceed for the consideration of the Council.

Some discussion ensued and it was agreed —

That, subject to Standing Order XVI all petitions addressed to the General Medical Council immediately before or during the session of the Council be laid upon the table.

The Council's Proceedings

Mr HORSLEY moved —

That a shorthand report should be made of all sittings of the Council and Executive Committee.

He thought that they would be only acting in conformity with other public bodies if they had such reports as he wanted of their proceedings.

Mr BROWN seconded the motion.

On a division the motion was rejected.

The London Apothecaries' Society

On the motion of Mr CARTER, seconded by Mr BRYANT, the Council resolved —

That Mr Charles Stonham, F.R.C.S., surgeon to and lecturer at the Westminster Hospital, be appointed an Assistant Examiner in Surgery to the Society of Apothecaries for a period of five years, in the room of Mr. Bernard Pitts, retiring by rotation.

The Dublin Apothecaries' Hall

As the appointment of assistant examiners in surgery at the Apothecaries' Hall, Dublin, expired on May 31st it was agreed that these assistant examiners should be reappointed.

Illegal Certificates in Midwifery

The Council proceeded to consider the following notices of business: (a) Adjourned consideration of the report by the Executive Committee (received and entered in the minutes of May 31st) on memorials on the subject of illegal certificates of proficiency in departments of medicine, surgery or midwifery. (b) To receive a memorial, dated March 30th, signed by 550 persons, on the subject of the alleged "improper conduct" of registered practitioners by participation in the issue to persons not medically registered of diplomas or certificates testifying or implying, or which may be used to testify or imply proficiency in departments of medicine, surgery, or midwifery.

Mr BROWN moved that the whole of the memorials be referred to the Special Committee on the subject appointed earlier in the session. He wished to impress upon the Council that the issues involved in these memorials were very important and in his view the Council could not give them at the end of their session that adequate discussion which was necessary. The memorialists were men who held the higher positions in the profession and he thought the Council should look upon the memorials, or petitions if they might be called by the latter name, as so important that they should not be thrown aside as of no account.

Mr HORSLEY was of the opinion that the Council was not in a position at that moment to fully consider the matter and he thought that it would be very much better if they postponed the whole business to the November session.

Dr MCVAIL said it seemed to him that the Executive Committee in the report presented by them to the Council on May 31st had gone as far as it was possible to go, and he could not see that they could get anything more from a special committee.

Dr MACALISTER considered that it would be most unwise to proceed further than the Executive Committee had gone in their finding.

Mr BRUDENELL CARTER wished to point out to the Council that there was nothing new in the matter of advertising by spectacle-makers. The only difference was that those who advertised now professed to be "certified" or "certificated." This whole business seemed to him to be utterly outside the province of the Council and he was not disposed to waste more time in considering whether spectacle-makers knew or did not know the difference between a concave and a convex lens.

On the motion of Mr BRYANT, seconded by Dr HORSLEY, the Council adopted the following resolution submitted by the Executive Committee —

That, as regards the issue of certificates in midwifery referred to in the memorials, the Council is of opinion that as a Midwives Bill is now

to recognise the senior examinations of the Welsh Intermediate Education Board and also the degree of science of the University of Wales

Appointment of Committees

The several committees of the Council were then appointed, the chief alterations being the replacing of Dr Church by Dr Payne on the Education Committee and the substitution of the name of Dr Pye Smith for that of Dr Church on the Public Health Committee

Dr Leech continues chairman of the Pharmacopœia Committee, Mr Bryant remains chairman of the Finance Committee, while the President will be *ex officio* chairman of the Dental Committee,

The Examination Committee will consist of the following members For England Sir Dyce Duckworth (chairman), Mr Bryant, and Mr Teale, for Scotland Dr Heron Watson, Dr Pettigrew, and Dr McVail, and for Ireland Dr Little, Sir William Thomson, and Sir Philip O Smyly

The Education Committee is composed of Dr MacAlister, Dr Glover, and Dr Payne for England, Sir John Batty Tuke (chairman), Sir William Gardner, and Dr Reid for Scotland, and Dr Bennett, Sir Christopher Nixon, and Sir William Thomson for Ireland

The members of the Public Health Committee are—for England Sir Richard Thorne (chairman), Mr Teale, and Dr Pye Smith, for Scotland Dr Hector Cameron, Dr McVail, and Dr Bruce, and for Ireland Dr Bennett, Sir Philip O Smyly, and Mr Tichborne

The Students' Registration Committee, with Sir Dyce Duckworth as Chairman, was also continued

Vote of Thanks

The proceeding of the Council terminated soon after five o'clock. The minutes of the sitting were read and confirmed. Just before separating, however, Dr GLOVER thought the Council ought to accord to the President a very cordial vote of thanks for the patience with which he had presided during this very prolonged session. Sir CHRISTOPHER NIXON supported this suggestion, which was received with applause by the members present

The Council rose till November next, the session having lasted for 10 working days, being the longest since the year 1885, when very important business detained Sir Richard Quain and his colleagues of that year for no fewer than 11 days

Medical News.

VICTORIA UNIVERSITY—The following degrees have been awarded—

Degree of Doctor of Science.—A. W. Crossley Edward Haworth, and Albert Griffiths, Owens College.

Degree of Doctor of Medicine.—* H. E. Annett, University College, and † O. A. Davies, * O. R. Marshall, † T. A. Rothwell, * et al. Thompson, and J. D. Windle Owens College

* Awarded gold medal. † Awarded mark of commendation.

THE LATE DR A. B. CHEVES—Some friends have placed a beautiful stained glass window in the side chapel of the parish church of Millbrook, Cornwall, as a memorial to the late Dr Alexander Bruce Cheves. The window consists of three lights and contains the following inscription: "To the Glory of God and in Memory of Alexander Bruce Cheves, M.D., 1899"

MANY of our readers will be aware of the recent and regretted death of Mr James Arnold, senior partner in the well known firm of surgical instrument makers, Messrs Arnold and Sons. Owing to an advertisement in our columns an impression has been given that the business of the firm would be for sale. We have been asked by the two remaining partners in the firm—Messrs J. E. and E. R. Arnold, sons of the deceased—to state that they will continue to conduct the business as heretofore

FREEMASONRY—*Rahere Lodge, No. 2546*—The installation meeting of the Rahere Lodge was held in the great hall at St Bartholomew's Hospital, E.C., on Tuesday, June 13th, in the presence of a large and brilliant assembly. Dr G. N. O. Slater, Dr Tunncliffe, and Dr H. W. O. Austen were initiated into freemasonry, and W. Bro Burns, the retiring master then installed Bro Reece as his successor. Bro Reece appointed Bros Gripper, Abraham,

and Godson to the principal offices in the Lodge. The report of the audit committee was received and adopted and showed that the Lodge was in a highly prosperous condition financially. The brethren and their guests to the number of 80 afterwards dined together at the Restaurant Frascati

VACCINATION GRANT—Mr Edward Knowles, M.D. Aberd., of Higher Trannere, Birkenhead, has been awarded the Government grant for efficient vaccination

BROCKWELL HALL—Messrs Burroughs, Wellcome, and Co have acquired Brockwell Hall, Herne Hill, and an extensive paddock adjoining it. The fine old mansion is now undergoing reconstruction to adapt it for use as physiological research laboratories

THE ROYAL INSTITUTE OF PUBLIC HEALTH—The annual dinner of this institution was held on June 7th at the Hotel Cecil, Dr W. R. Smith, President, being in the chair. Among those present were the Archbishop of Canterbury, Lord Lister, Sir William Turner, Sir Michael Foster, Sir William Broadbent, Sir James Onychon Browne, and Sir Dyce Duckworth. The chairman proposed the health of Lord Lister to whom the Institute had awarded the Harben Medal for the year. Lord Lister in an appropriate reply referred to the enormous development in recent years of the study of bacteriology and the effect of this study upon preventive medicine. The Archbishop of Canterbury proposed the toast of "Prosperity to the Institute," to which Dr Smith responded in suitable terms

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS—The annual meeting of the governors of this society was held on June 12th at 12, Buckingham Street, Strand, the chair being taken by Mr E. Montefiore Micholls. The chairman, in his introductory speech, referred to the forthcoming opening by the Duke and Duchess of York of four new homes at the colony established by the society at Chalfont. Two of these homes were intended for children, and the committee looked to this extension of the work with the most confident anticipations of good results. It was hoped that ere long the recommendations made by the recent committee of the Education Department would be carried into effect by legislation so as to enable school boards throughout the country to send epileptic children to such homes. The work which the society had in hand was of national importance, it was too vast to be wholly accomplished by the unaided resources of voluntary charity, and it could best be performed by a system of co-operation between school boards and other public authorities on the one hand and voluntary agencies such as that society on the other. This view had been fully recognised by the departmental committee to which he had referred. Another extension about to be made in the society's work would take the form of a home for convalescent and other temporary cases, an offer of £2500 for this purpose having been made by a gentleman whose name he was not at liberty to divulge. Epileptics were rigorously excluded from the ordinary convalescent homes, and the need for a special home to receive such cases had long been felt. The progress of the society during its brief existence was probably almost without a parallel amongst charitable institutions. Its success was to be attributed in the first place to the merits of the cause and to the full though tardy awakening of the public conscience to a feeling that the former neglect of epileptics must no longer be permitted. To the personal interest taken in the movement by the Duke of York as president the society owed much and much also to the heartiness and unanimity with which it had been supported by the press. The annual reports of the executive committee and the honorary medical staff were then received and adopted. The first-named report showed that notwithstanding the growth of the colony its accommodation was still quite incommensurate with the need. The urgent necessity for further extension was pointed out and the committee urged very forcibly that such extension could be made without causing any difficulty as to the future maintenance of the institution. It appeared from the report that owing to the press of applications candidates had to wait on the average two years for admission, and during that time the disease naturally became confirmed and aggravated. In spite of this obstacle the progress made by the colonists, as shown by the report of the honorary medical staff, was regarded as equalling the most sanguine expectations

Parliamentary Intelligence.

HOUSE OF COMMONS

THURSDAY, JUNE 22ND.

The Finance Bill in India

Sir WILLIAM WINDHAM asked the Secretary of State for India whether his attention had been drawn to the proceedings of a Central Committee of the Revenue Institute held on April 15th last at the office of the Director-General of Indian Medical Service at Simla (the Director-General himself in the chair), when it was proposed to ask the Government to make a grant for a Finance Institute to be placed under a Government medical officer, whether the Committee had been formed with the sanction of Government, and whether it was proposed to grant the Institute a report of the Government of India are I believe, aware of the reasons and proceedings of the Committee, but a respectful notice was sent that they had not decided on their course of action. They hoped, however, to deal with the question during the present summer.

The Addition of Tea

Mr. FORSTER asked the Chancellor of the Exchequer if his attention had been called to a statement in the press that a quarter of 1500 per cent of the price of tea had been added to the cost of the tea in the market, and whether the Government could do anything to prevent this. The Chancellor replied that he had no information of the matter, and that the Board of Customs had been called upon to make a report on the matter. The Board of Customs had been called upon to make a report on the matter, and the Board of Customs had been called upon to make a report on the matter.

An Amendment for the House of Parliament

Two questions were addressed to the First Commissioner of Works and to the Secretary of the House of Commons. The first question was whether the House of Commons could be called upon to make a report on the matter, and the second question was whether the House of Commons could be called upon to make a report on the matter.

At the meeting of the House of Commons on June 17th, 1899, the following business was transacted:—The House met at 10.15 a.m. The Speaker, Mr. Balfour, presided. The House was called to order by Mr. Balfour. The House then proceeded to the consideration of the Finance Bill.

During the discussion of the Finance Bill, the following amendments were proposed:—The House of Commons should be called upon to make a report on the matter, and the House of Commons should be called upon to make a report on the matter.

The House of Commons then proceeded to the consideration of the Finance Bill. The House of Commons then proceeded to the consideration of the Finance Bill. The House of Commons then proceeded to the consideration of the Finance Bill.

Appointments.

WEDNESDAY, JUNE 21ST.

Medical Officers of Health

Mr. Balfour asked the Secretary of State for India whether his attention had been drawn to the proceedings of a Central Committee of the Revenue Institute held on April 15th last at the office of the Director-General of Indian Medical Service at Simla (the Director-General himself in the chair), when it was proposed to ask the Government to make a grant for a Finance Institute to be placed under a Government medical officer, whether the Committee had been formed with the sanction of Government, and whether it was proposed to grant the Institute a report of the Government of India are I believe, aware of the reasons and proceedings of the Committee, but a respectful notice was sent that they had not decided on their course of action. They hoped, however, to deal with the question during the present summer.

At the meeting of the House of Commons on June 17th, 1899, the following business was transacted:—The House met at 10.15 a.m. The Speaker, Mr. Balfour, presided. The House was called to order by Mr. Balfour. The House then proceeded to the consideration of the Finance Bill.

to recognise the senior examinations of the Welsh Intermediate Education Board and also the degree of science of the University of Wales

Appointment of Committees

The several committees of the Council were then appointed, the chief alterations being the replacing of Dr Church by Dr Payne on the Education Committee and the substitution of the name of Dr Pye Smith for that of Dr Church on the Public Health Committee

Dr Leech continues chairman of the Pharmacopœia Committee, Mr Bryant remains chairman of the Finance Committee, while the President will be *ex officio* chairman of the Dental Committee,

The Examination Committee will consist of the following members. For England Sir Dyce Duckworth (chairman), Mr Bryant, and Mr Teale, for Scotland Dr Heron Watson, Dr Pettigrew, and Dr McVail, and for Ireland Dr Little, Sir William Thomson, and Sir Philip O Smyly

The Education Committee is composed of Dr MacAlister, Dr Glover, and Dr Payne for England, Sir John Batty Tuke (chairman), Sir William Gardner, and Dr Reid for Scotland, and Dr Bennett, Sir Christopher Nixon, and Sir William Thomson for Ireland

The members of the Public Health Committee are—for England Sir Richard Thorne (chairman), Mr Teale, and Dr Pye Smith, for Scotland Dr Hector Cameron, Dr McVail, and Dr Bruce, and for Ireland Dr Bennett, Sir Philip O Smyly, and Mr Tichborne

The Students' Registration Committee, with Sir Dyce Duckworth as Chairman, was also continued

Vote of Thanks

The proceeding of the Council terminated soon after five o'clock. The minutes of the sitting were read and confirmed. Just before separating, however, Dr GLOVER thought the Council ought to accord to the President a very cordial vote of thanks for the patience with which he had presided during this very prolonged session. Sir CHRISTOPHER NIXON supported this suggestion, which was received with applause by the members present

The Council rose till November next, the session having lasted for 10 working days, being the longest since the year 1885, when very important business detained Sir Richard Quain and his colleagues of that year for no fewer than 11 days

Medical News.

VICTORIA UNIVERSITY—The following degrees have been awarded —

Degree of Doctor of Science.—A. W. Crossley Edward Haworth, and Albert Griffiths, Owens College.

Degree of Doctor of Medicine.—* H. B. Annett, University College, and * O. A. Davies, * C. R. Marshall, * T. A. Rothwell * eter Thompson and J. D. Windle Owens College.

* Awarded gold medal. † Awarded mark of commendation.

THE LATE DR A. B. CHEVES—Some friends have placed a beautiful stained glass window in the side chapel of the parish church of Millbrook, Cornwall, as a memorial to the late Dr Alexander Bruce Cheves. The window consists of three lights and contains the following inscription "To the Glory of God and in Memory of Alexander Bruce Cheves, M.D., 1899"

MANY of our readers will be aware of the recent and regretted death of Mr James Arnold, senior partner in the well known firm of surgical instrument makers, Messrs Arnold and Sons. Owing to an advertisement in our columns an impression has been given that the business of the firm would be for sale. We have been asked by the two remaining partners in the firm—Messrs J. E. and E. R. Arnold, sons of the deceased—to state that they will continue to conduct the business as heretofore

FREEMASONRY—*Rahere Lodge, No 2546*—The installation meeting of the Rahere Lodge was held in the great hall at St Bartholomew's Hospital, E.C., on Tuesday, June 13th, in the presence of a large and brilliant assembly. Dr G. N. O. Slater, Dr Tunnicliffe, and Dr H. W. C. Austen were initiated into freemasonry, and W. Bro Burns, the retiring master, then installed Bro Reece as his successor. Bro Reece appointed Bros Gripper, Abraham,

and Godson to the principal offices in the Lodge. The report of the audit committee was received and adopted and showed that the Lodge was in a highly prosperous condition financially. The brethren and their guests to the number of 80 afterwards dined together at the Restaurant Frascati

VACCINATION GRANT—Mr Edward Knowles, M.D. Aberd., of Higher Tramere, Birkenhead, has been awarded the Government grant for efficient vaccination

BROCKWELL HALL—Messrs Burroughs, Wellcome, and Co have acquired Brockwell Hall, Herne Hill, and an extensive paddock adjoining it. The fine old mansion is now undergoing reconstruction to adapt it for new physiological research laboratories

THE ROYAL INSTITUTE OF PUBLIC HEALTH—The annual dinner of this institution was held on June 7th at the Hotel Cecil, Dr W. R. Smith, President, being in the chair. Among those present were the Archbishop of Canterbury, Lord Lister, Sir William Turner, Sir Michael Foster, Sir William Broadbent, Sir James Crichton Browne, and Sir Dyce Duckworth. The chairman proposed the health of Lord Lister to whom the Institute had awarded the Harben Medal for the year. Lord Lister in an appropriate reply referred to the enormous development in recent years of the study of bacteriology and the effect of this study upon preventive medicine. The Archbishop of Canterbury proposed the toast of "Prosperity to the Institute," to which Dr Smith responded in suitable terms

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS—The annual meeting of the governors of this society was held on June 12th at 12, Buckingham Street, Strand, the chair being taken by Mr E. Montefiore Micholls. The chairman, in his introductory speech, referred to the forthcoming opening by the Duke and Duchess of York of four new homes at the colony established by the society at Chalfont. Two of these homes were intended for children, and the committee looked to this extension of the work with the most confident anticipations of good results. It was hoped that ere long the recommendations made by the recent committee of the Education Department would be carried into effect by legislation so as to enable school boards throughout the country to send epileptic children to such homes. The work which the society had in hand was of national importance, it was too vast to be wholly accomplished by the unaided resources of voluntary charity, and it could best be performed by a system of coöperation between school boards and other public authorities on the one hand and voluntary agencies such as that society on the other. This view had been fully recognised by the departmental committee to which he had referred. Another extension about to be made in the society's work would take the form of a home for convalescent and other temporary cases, an offer of £2500 for this purpose having been made by a gentleman whose name he was not at liberty to divulge. Epileptics were rigorously excluded from the ordinary convalescent homes, and the need for a special home to receive such cases had long been felt. The progress of the society during its brief existence was probably almost without a parallel amongst charitable institutions. Its success was to be attributed in the first place to the merits of the cause and to the full though tardy awakening of the public conscience to a feeling that the former neglect of epileptics must no longer be permitted. To the personal interest taken in the movement by the Duke of York as president the society owed much and much also to the heartiness and unanimity with which it had been supported by the press. The annual reports of the executive committee and the honorary medical staff were then received and adopted. The first-named report showed that notwithstanding the growth of the colony its accommodation was still quite incommensurate with the need. The urgent necessity for further extension was pointed out and the committee urged very forcibly that such extension could be made without causing any difficulty as to the future maintenance of the institution. It appeared from the report that owing to the press of applications candidates had to wait on the average two years for admission, and during that time the disease naturally became confirmed and aggravated. In spite of this obstacle the progress made by the colonists, as shown by the report of the honorary medical staff, was regarded as equalling the most sanguine expectations

THE VALUE OF PROFESSIONAL UNIONS

[illegible]

To the Editors of THE LANCET

Sins—The unequalled class of medical gentlemen fill fourteen

[illegible]

interfering with any case unless a statutory declaration be made before a magistrate or a commissioner of oaths. What is the use of the General Medical Council presiding in a way in which it is stated that any medical man employing an unqualified assistant is liable to a fine of £500? This notice was sent to a validly qualified man on the 11th inst. and yet the firm of surgeons employed him as one of its. I do not understand why any examination should be made of cases in which the General Medical Council upon hearing of cases in which the resolutions are taken and no notice of would have gone into the matter themselves and have their best to stop this scandal to the medical profession. Would it not be better before allowing Italians to practice in England to see that the profession is carried on decently at home?

I am, Sir, yours faithfully

"M.B.C.s Ed." In his letter he does not clearly comprehend what is the real scope of the work of the General Medical Council, of Medical Education and Registration, or of the United Kingdom, to give the body its correct name, was created for the good of the public, to keep a Register of qualified medical practitioners so that the public may know who are and who are not persons may find their way in to the pages of this Register. It becomes the duty of the General Medical Council to insist upon a proper educational standard being exacted from their students by all corporations and universities granting medical titles. That only the names of persons possessing that degree of moral reputation and competence which all civilized people demand of their medical students is given power to expunge from the roll the names of persons proved unworthy to remain members of the medical profession. This last task of the General Medical Council is neither the important nor the less important of the two.

M.R.C.S. Eng., the Council would have neither time nor opportunity to discuss the larger section of his work. But to satisfy

only when a physician is brought into court in accordance with legal formalities can he be tried and punished. Here the parallel between the High Court and the General Medical Council ceases, for the Council is not assisted by policemen and detectives to try nothing but the most maliciously concocted cases for the preservation and punishment of the medical profession. The High Court is not assisted by policemen and detectives to try nothing but the most maliciously concocted cases for the preservation and punishment of the medical profession. The High Court is not assisted by policemen and detectives to try nothing but the most maliciously concocted cases for the preservation and punishment of the medical profession.

The Council has no provision in the act for the expenditure of money on the purchase of land or buildings, or for the payment of salaries or wages to its officers or employees.

with similar objects, he can lay the matter before them produce the detailed evidence of which he is the possessor and expect the general Council to take action as common informant would do. He will be able to bring the case to the General Council with the certainty of its receiving proper attention and will no fear lest anyone should cast upon him the imputation of having been accused by professional jealousy. He sympathises with him in his view that the General Medical Council is placed in an unfortunate position when it issues a strict censure which members of the medical profession can disregard with impunity. But it is wrong not to contribute to the General Medical Council because it does not do its own difficult work. The regulations of the Council concern the employment of unqualified assistants was issued in regard to the medical profession as large and, finally, as they pressed upon the members of the medical profession and on the whole of a large class of persons who were associated with the good of the profession. It is the object of the profession by united action to assist the Council in enforcing their regulations.

THE MEMORIALS OF THE CORPORATE AND MEDICAL REFORM ASSOCIATION LIMITED

The Corporate and Medical Reform Association Limited desires to acknowledge with thanks the following further donations to its Special Voluntary Fund for the purposes of the memorials against unqualified practitioners (midwives and opticians) The resolutions of the General Medical Council on June 8th in reply to the memorials concede the principle affirmed by the memorialists, but until applied by means of successful legislation are valueless for practical purposes and the maintenance of the above important principles & every constitutional means calls for further combined and energetic action.

A. J. F. S.

their private clubs have recourse to employing men generally (a) as collectors of whom there are a few in the country, and (b) as a reserve force of men who are not only of secure membership (a) but also of high character and high intelligence. It would be justifiable to provide a reserve force of men who are not only of secure membership (a) but also of high character and high intelligence. It would be justifiable to provide a reserve force of men who are not only of secure membership (a) but also of high character and high intelligence.

WHAT IS YOUR FEE?
To the Editors of THE LANCET

Sms.—At Marlborough County Court on June 1st in a case in which I was plaintiff I was asked "What is your fee?" I might truthfully have answered that I have accepted 12 guineas as a fee where the patient's friends were not in a position to pay 20 guineas and that for a case infinitely less than that with expressions of gratitude to pay 20 guineas and that the patient's friends were not in a position to give thousands of pounds for a public-house was not in a position to give thousands of pounds for a public-house. They could appreciate the value of professional services in the present case. I had seen and attended to the patient six times and I made and very moderate. The defence was "that on a previous occasion I had attended defendant on 1st for each attendance." It was suggested that my fee was 5. I stated that my usual fee in such a case would be 10. But it was true that in the case of poor people I stated that my usual fee in such a case would be 10.

DEATHS

FERGUSON.—Suddenly at Cove Hotel on June 7th Major Ferguson I. M.S., second son of the late John Ferguson, M.D. M.R.C.S. Lond., Kincardine.
 PARR.—On June 10th, at Upper Phillimore-place Kensington, George Charles Parr M.D. aged 66.
 TAIT.—On June 13th, at his residence St. Petrock's Llandudno West, Lawson Tait aged 61.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

he supposed from appearances that it was all the patient could afford. A few days afterwards the boy appeared again and said he had "come to have the stitches out." Being asked if he had any money he said, "Oh no I paid the *shilling* the other night." Being told that he would not be looked at without a further payment he shortly reappeared with the required coin. The sutures were removed a few days afterwards when a third *shilling* was paid. The wound had healed by first intention and no further treatment was necessary. Some two months afterwards a well-dressed, prosperous looking man came in bringing with him a little girl with a wounded forehead. My son wished to put in a suture but the father objected, so it was dressed otherwise. The next day the father came again with the child. I saw him asked his name and address and that was the first time that I knew of the existence of the licensed victualler and public-house proprietor who became defendant in this case. Though near my house I did not even know the name of the hotel till he told me. Seeing before me a man of means I said nothing about payment unless I may have suggested that it had better stand over until the case was concluded, his appearance and address being sufficient guarantee that the money would be forthcoming when the case was completed. I supplied bandages lint protective issue, &c., regardless of cost, and brought the case to a successful issue the scar which from want of a suture might have been a sad disfigurement on the forehead of a pretty girl being scarcely perceptible. Now the attendance involved 51 dressings but wishing to avoid anything that might be considered overcharge I made an inclusive charge of five guineas, offering a reduction even on that if desired provided it were settled by a certain date. No notice was taken of this and eventually I had to put the case in the county court.

The judge ruled that as I had attended the boy for 1s each attend ance I could not claim more for the girl and obliged me to accept about half my claim. Is it justice?

I am, Sirs yours faithfully,

M R O S E N G., &c.

June 3rd 1899

VERMINOUS CLOTHING

To the Editors of THE LANCET

SIRS—At a small general hospital recently opened in our town we have had considerable difficulty in dealing with patients verminous clothing before storing them. We have no steam apparatus about the house and it is not worth our while going to the expense (which would be considerable) of a special steam press for the sake of dealing with one or two suits in the month. Much of the clothing would not survive boiling or even soaking in germicidal solutions. I have thought of constructing a small chamber in which such clothes could be suspended in an atmosphere periodically saturated with some volatile "insecticide" such as formalin, &c. I shall be much indebted to any of your readers who can tell us how similar difficulties have been overcome elsewhere.

I am Sirs, yours faithfully,

PED CORP

June 14th, 1899

MEDICAL PRACTICE IN MASHONALAND

I answer to Artagall's query in THE LANCET of April 8th "H S" writing from the British South Africa Company's Hospital, Umtali, says "As to the prospects of a medical man settling in Mashonaland I am afraid I cannot give an encouraging reply. At present the population is too thin and scattered the population of the whole country just now not exceeding that of a moderate-sized Yorkshire village. There are five townships—Salisbury, Umtali, Victoria, Melsitte, and Enkeldoorn. Salisbury and Umtali have nine medical men each of the other three are looked after by the Government district surgeons, certain other districts such as Hartley Lomagundi and the Abercorn, where British South African police are stationed are attended to by police surgeons. I imagine it will be some time before the population of either of these districts would warrant the presence of another medical man. If Artagall really wishes to settle in Mashonaland I should advise him to apply at the British South African Company's office in Cape Town until he gets an appointment. I do not think vacancies are ever filled in England. The country is excessively healthy and except during the summer-autumn period after the rains, when malaria is somewhat prevalent, there is very little work to do."

THE MOVIMENTO DEMOGRAFICO IN ITALY

THE latest official return under this head has features of special interest. During 1897 there were born in Italy 1,101,848 additions to the population and there died of that number 695,602. Of the births 566,654 were males and 535,194 females of the deaths 352,038 were males and 343,564 females. From 1872 onwards the year in which the death rate was highest was 1880 with the portentous total of 569,992 deaths. The greatest number of births was in 1887—amounting to 1,152,906. The greatest percentage of births was in the Abruzzi (40.24 per 1000 inhabitants) the smallest in Piedmont (29.53 per 1000). Latium has 35.79 and Lombardy 35.31. The number of illegitimate births in 1897 was 70,199 sub-divided into 35,763 males and 34,436 females. Of the total of illegitimate children 41,368 were recognised by one or both of their parents the other 28,831 were not but relegated in most cases to the tender mercies of the Brevetorio (foundling hospital) with its scandalously high death rate—sometimes cent. per cent. The highest total of illegitimate births comes from Latium (which figures almost in the

first line) from the Romagna, and from Sicily. In 1897 there were in all Italy 13,124 double births and 174 triplets. In these latter Lombardy beats the record "with its 23, then comes Venice with 27. In the Roman province for all the year there were seven cases of triplets. Finally Liguria produced one case, unique in the Italian kingdom, of a parto quadruplo" (quadruple birth)—a mother having given to the world four females at once.

A QUESTION OF SEWAGE DISPOSAL

To the Editors of THE LANCET

SIRS—Would any of your readers be so kind as to advise me as to the best brochure on sewage disposal for a limited population where water carriage is not available? The problem with which I have to deal is that of a colony of some 1500 or 2000 workmen to be housed round some works, the whole occupying some hundred acres of level ground. The soil consists of a foot or so of humus and beneath this a deep layer of dense argillaceous clay. The first water bearing level is about 30 feet from the surface, but the water-supply would probably be obtained from a deep boring drawing the water from a second water layer some 300 feet deep. The workmen are chiefly Italians and the system to be adopted must be simple. In another case under very similar circumstances, but in which the workmen were housed in wooden huts that were frequently moved, we adopted a system of shallow pits one set for rubbish and another set over which closets were erected, and these pits were frequently drenched with a load of lime and finally refilled with soil, a new pit being excavated a few yards distant. In the present case the workmen will be housed in permanent dwellings and some pit system seems inevitable.

I am, Sirs, yours faithfully,

M.D.

ICE-CREAMS

To the Editors of THE LANCET

SIRS—The season for the street and seashore "ice-cream" vendor is now here again with us and again are to be seen groups of children investing their coppers and joyously swallowing anything that is handed to them. Will you, Sirs, once again say a word for the small ones and urge that everything possible may be done by the authorities to see that the interests of the children are protected and that what is sold to them may be at all events free from any danger to their health? The general appearance of one vendor whom I saw serving a group of hearty little boys suggested awful possibilities to my mind and haunts me and compels me to write this to you.

I am, Sirs, yours faithfully,

NEMO (Surgeon)

THE MICROPHONOGRAPH

CAN any of our readers inform a correspondent where he can obtain full particulars concerning M. Dussaud's microphonograph?

E. B.—The treatment is not one concerning which our readers are likely to have anything complimentary to say. It is not founded upon medical principles nor are the homes—which we understand to be as a rule expensive out of all proportion to the attention provided—necessarily under medical charge. The only book we have seen upon this subject was written by a layman.

Inspector.—The first circular which does not emanate from a medical man, should only have been sent to patients of the deceased, especially in view of the offer to call upon such patients. We do not see why exception should be taken to the second circular.

Inquirer will find the information which he seeks in the introductory chapters to Churchill's Medical Directory. If he requires to know anything more in detail with respect to any particular service or appointment we will assist him.

X. Y. Z.—The inaugural meeting of the Cancer Society was held on Friday June 8th, Sir Charles Cameron M.P., presiding. We do not know where the offices are.

Inquirer (J. H.)—The expression is used as our correspondent surmises.

T. H.—The general subject of hair dyes is not strictly a medical one.

be supposed from appearances that it was all the patient could afford. A few days afterwards the boy appeared again and said he had 'come to have the stitches out.' Being asked if he had any money he said, 'Oh no, I paid the shilling the other night.' Being told that he would not be looked at without a further payment he shortly reappeared with the required coin. The sutures were removed a few days afterwards when a third shilling was paid. The wound had healed by first intention and no further treatment was necessary. Some two months afterwards a well-dressed, prosperous looking man came in bringing with him a little girl with a wounded forehead. My son wished to put in a suture but the father objected, so it was dressed otherwise. The next day the father came again with the child. I saw him asked his name and address and that was the first time that I knew of the existence of the licensed victualler and public-house proprietor who became defendant in this case. Though near my house I did not even know the name of the hotel till he told me. Seeing before me a man of means I said nothing about payment unless I may have suggested that it had better stand over until the case was concluded his appearance and address being sufficient guarantee that the money would be forthcoming when the case was completed. I supplied bandages lint protective tissue &c., regardless of cost, and brought the case to a successful issue, the scar which from want of a suture might have been a sad disfigurement on the forehead of a pretty girl, being scarcely perceptible. Now, the attendance involved 51 dressings but wishing to avoid anything that might be considered overcharge I made an inclusive charge of five guineas, offering a reduction even on that if desired, provided it were settled by a certain date. No notice was taken of this and eventually I had to put the case in the county court.

The judge ruled that as I had attended the boy for 1s each attend ance I could not claim more for the girl, and obliged me to accept about half my claim. Is it justice?

I am, Sirs, yours faithfully,

June 3rd 1899

M. I. O. S. E. S. & C.

VERMINOUS CLOTHING

To the Editors of THE LANCET

SIRS—At a small general hospital recently opened in our town we have had considerable difficulty in dealing with patients verminous clothing before storing them. We have no steam apparatus about the house and it is not worth our while going to the expense (which would be considerable) of a special steam press for the sake of dealing with one or two suits in the month. Much of the clothing would not survive boiling or even soaking in germicidal solutions. I have thought of constructing a small chamber in which such clothes could be suspended in an atmosphere periodically saturated with some volatile "insecticide" such as formalin, &c. I shall be much indebted to any of your readers who can tell us how similar difficulties have been overcome elsewhere.

June 14th 1899

I am, Sirs, yours faithfully,

PED CORP

MEDICAL PRACTICE IN MASHONALAND

IN answer to Artegal's query in THE LANCET of April 8th "H S," writing from the British South Africa Company's Hospital, Umtali, says: 'As to the prospects of a medical man settling in Mashonaland I am afraid I cannot give an encouraging reply. At present the population is too thin and scattered the population of the whole country just now not exceeding that of a moderate-sized Yorkshire village. There are five townships—Salisbury, Umtali, Victoria, Melilite, and Enkeldoorn. Salisbury and Umtali have nine medical men each of the other three are looked after by the Government district surgeons, certain other districts such as Hartley Lomajundis and the Abercorn, where British South African police are stationed are attended to by police surgeons. I imagine it will be some time before the population of either of these districts would warrant the presence of another medical man. If Artegal really wishes to settle in Mashonaland I should advise him to apply at the British South African Company's office in Cape Town until he gets an appointment. FED CORP

MEDICAL PRACTICE IN MASHONALAND

In answer to Artegan's query in THE LANCET of April 8th 'H S,' writing from the British South Africa Company's Hospital Umtali, says: As to the prospects of a medical man settling in Mashonaland I am afraid I cannot give an encouraging reply. At present the population is too thin and scattered the population of the whole country just now not exceeding that of a moderate-sized Yorkshire village. There are five townships—Salisbury, Umtali, Victoria, Mellette, and Enkeldoorn. Salisbury and Umtali have nine medical men each of the other three are looked after by the Government district surgeons, certain other districts such as Hartley Lomagundi and the Abercorn, where British South African police are stationed, are attended to by police surgeons. I imagine it will be some time before the population of either of these districts would warrant the presence of another medical man. If Artegan really wishes to settle in Mashonaland I should advise him to apply at the British South African Company's office in Cape Town until he gets an appointment. I do not think vacancies are ever filled in England. The country is excessively healthy and except during the summer/autumn period after the rains, when malaria is somewhat prevalent, there is very little work to do."

THE 'MOVIMENTO DEMOGRAFICO' IN ITALY

THE latest official return under this head has features of special interest. During 1897 there were born in Italy 1,101,648 additions to the population and there died of that number 695,602. Of the births 568,654 were males and 535,194 females of the deaths 352,038 were males and 343,664 females. From 1872 onwards the year in which the death rate was highest was 1880 with the portentous total of 869,992 deaths. The greatest number of births was in 1887—amounting to 1,162,906. The greatest percentage of births was in the Abruzzi (40.24 per 1000 inhabitants) the smallest in Piedmont (29.58 per 1000). Latium has 35.79 and Lombardy 35.31. The number of illegitimate births in 1897 was 70,199, sub-divided into 35,763 males and 34,436 females. Of the total of illegitimate children 41,368 were recognised by one or both of their parents the other 28,833 were not but relegated in most cases to the tender mercies of the Bredotrolo (foundling hospital) with its scandalously high death rate—sometimes cent. per cent. The highest total of illegitimate births comes from Latium (which figures almost in the

first line) from the Romagna, and from Sicily. In 1897 there were in all Italy 13,124 double births and 174 triplets. In these latter Lombardy beats the record with its 23, then comes Venice with 27. In the Roman province for all the year there were seven cases of triplets. Finally Liguria produced one case unique in the Italian kingdom of a "parto quadruplo" (quadruple birth)—a mother having given to the world four females at once.

A QUESTION OF SEWAGE DISPOSAL

To the Editors of THE LANCET

SIRS,—Would any of your readers be so kind as to advise me as to the best brochure on sewage disposal for a limited population where water carriage is not available? The problem with which I have to deal is that of a colony of some 1500 or 2000 workmen to be housed round some works, the whole occupying some hundred acres of level ground. The soil consists of a foot or so of humus and beneath this a deep layer of dense argillaceous clay. The first water-bearing level is about 30 feet from the surface, but the water supply would probably be obtained from a deep boring drawing the water from a second water layer some 360 feet deep. The workmen are chiefly Italians and the system to be adopted must be simple. In another case under very similar circumstances, but in which the workmen were housed in wooden huts that were frequently moved, we adopted a system of shallow pits one set for rubbish and another set over which closets were erected and these pits were frequently drenched with a load of lime and finally refilled with soil, a new pit being excavated a few yards distant. In the present case the workmen will be housed in permanent dwellings and some pall system seems inevitable.

SOME POINTS CONNECTED WITH SLEEP, SLEEPLESSNESS, AND HYPNOTICS

Delivered before the Royal College of Physicians of London

BY JOHN BUCKLEY BRADBURY,

MD CANTAB,

TOP OF THE COLLEGE DOWNING PROFESSOR
UNIVERSITY OF CAMBRIDGE AND SECTION
UNDERWOOD'S HOSPITAL

LECTURE I

Delivered on June 24th, 1893

Mr. PRESIDENT AND GENTLEMEN,—When the late President did me the great honour of asking me to deliver the Croonian Lectures for 1859 I felt some diffidence in accepting the invitation, but on thinking the matter over it occurred to me that some points connected with sleep, hypnotics, and hypnotism which had engaged my attention might possibly be of sufficient interest to bring before the College. Let me therefore thank the College for the interest which was entrusted to me and ask you to consider me in the first place

THE PHYSIOLOGY OF SLEEP

[illegible]

Communications, Letters, &c., have been received from—

A.—Dr A. R. Aldridge Cherat; Article Club Lond.; Secretary of Mons J Astier, Paris; Messrs. Allen and Hanbury, Lond.; Mons. F. Alcan, Paris; Ancots Hospital, Manchester, Secretary of Dr J Alkman, Guernsey

R.—Mons. O. Berthier Paris Mr O A G Browne, Lond.; Messrs. Bates, Hendy and Co., Reading Bradford Royal Infirmary Secretary of; T B. Browne, Ltd Lond.; Mr A. B. Barker, Lond. Borough Hospital, Birkenhead Secretary of; Borough of Burton on Trent, Town Clerk of; Messrs. H. Booth and Sons, Oldham Birmingham Faculty of Medicine, Dean of Messrs. Burgoyne, Burdidge, and Co., Lond.

C.—Mr F. Candy, Lond., Messrs. E. Cook and Co., Lond.; Christy Saddle Co., Lond. Messrs. Crossley, Moir and Co., Lond. Mr E. L. Cave Bromyard; Mr O. R. Cheesman, Bushey Messrs. G. W. Carrick and Co., New York.

D.—Dr E. Das, Calcutta Messrs. Davy, Hill, and Son, Lond.; Derbyshire Royal Infirmary Derby, Secretary of

E.—Messrs. Eason and Son, Dublin.

F.—Miss J. Ferguson, Broughty Ferry

G.—Dr J. Galloway Lond. Mr R. O. Gibb, St. Leonards Mr T. Godson, Appledore; Mr Penn Gaikell Lond.

H.—Dr W. E. Home, Hong Kong Hornsea Advertising Agency, Lond. Mrs. Hussey Oxford H. G.; Lady Charlotte Home Christchurch Mr J. Heywood, Manchester Mr J. T. Hialop Harrogate Dr G. A. Heron, Lond.

J.—Dr N. B. Jenkins, Knoxville, U.S.A.; J. S.

K.—Dr R. Kirk, Partick; King Arthur's Castle Hotel Co., Tintagel; Kidderminster Medical

Society, Secretary of Dr J. M. M. Herr Glasgow

L.—Dr E. S. Lee, Lucerne Liverpool Northern Hospital Secretary of Lancaster Union, Clerk of London Throat Hospital, Hon. Secretary of London Gersap Co., Lond.

M.—Mr M. D. Makuna, Troherbert Mill House, Minstead; Messrs. Maple and Co., Lond. Milk Preparations Co., Brentwood; Maitine Manufacturing Co., Lond. Mr J. Milne, Lond.; Manor Farm Dairy, Lond. Dr J. D. McCaw Lond.; Messrs. Mayer and Meltzer, Lond. M. B. G.; Mr J. McMurtrie, Glasgow; Messrs. Macmillan and Co., Lond.

N.—Dr J. T. O. Nash, Lond. Mr H. Needes, Lond.

O.—Messrs. Oliver and Boyd, Edinburgh.

P.—Dr W. H. Price Wordsborough Bridge Messrs. Parke Davis, and Co., Lond. Mr Young J. Pentland, Edinburgh Parish of Eday Clerk of Mr F. Piggett, Cambridge.

R.—Mr E. J. Held Lond.; Ramsgate and St. Lawrence Royal Dispensary Secretary of; Retreat (The) Fairford, Proprietor of Messrs. Ranton and Smith, Chester-le Street.

S.—Dr G. H. Stewart, Netley Messrs. Squire and Son, Lond. Messrs. Street and Co., Lond.; Messrs. Simpkin, Marshall, and Co., Lond. St. Bartholomew's Hospital Medical School, Lond., Secretary of Mr S. J. Suleman, Dr J. B. Squire Lond.; Societe Anonyme des Instituts Marins, Paris Mr H. L. Smith, Bulawayo; Sanitary Institute, Secretary of Messrs. W. H. Smith and Son, Liverpool; Mr F. W. Sears, Lond. Messrs. W. H. Smith and Son, Lond. Mr J. L. Stack, Chicago Stockton and Thornaby Hospital, Stockton-on Tees, Secretary of.

T.—Dr G. Thornton, Lond. Dr H. E. Thompson Birmingham.

V.—Mr J. W. Vickers, Lond.

W.—Mr W. G. Wardrop, Ballarat Mr P. M. Wood Ashfield New South Wales, Mr A. Watts, Lond. Mr E. Dudley Ward, Lond.; Messrs. Wright, Laymen and Umney, Lond. Dr J. S.

Walker, Hanley Wade Disinfectant Syndicate Lond. Herr Winckler, Friednau W. G. West Bromwich District Hospital, Secretary of Messrs. J. Wright and Co., Bristol; Dr A. F. Wilson, Folkestone; J. Willing Ltd., Lond. Mrs. Williams, Poole.

X.—A., Leeds.

Letters, each with enclosure, are also acknowledged from—

A.—Mr J. E. Anderton, New Mills Mr F. W. Alexander Lond.

A. O. A. O. F. Mr F. O. Allen, Dudley; A. K. I. Mr J. V. Arkle Dunedin New Zealand.

R.—Dr G. G. Bothwell, Hull; Mr O. Birchall Liverpool Sir Hugh Beavor, Bart. Lond. Borough Asylum, Portsmouth.

this view the transmission of nervous impulses presents no obstacle. Another theory of the function of these gemmules and the transmission of impulses has been put forward by Berkley. He accepts the knob like terminations of the gemmules as natural, but he cannot accept Ramón y Cajal's theory that nervous forces may discharge themselves from axites to dendrites all along the line. The dendrites he believes, are covered with a thin enveloping sheath through which the gemmules penetrate, and it is only at the tip of the gemmules that naked protoplasm exists. Similarly the fine branches of the axites are covered with "a protective sheath of great tenuity" and only exhibit naked protoplasm at their bulbous terminations. Therefore Berkley believes that it is only between these free terminations that nerve impulses can pass. The mode of branching of the axites varies according as they form ascending fibres (extrinsic) or belong to local cells (intrinsic). The extrinsic break up into a number of filaments, usually at some distance from one another, which re-divide into a small number of others. These course over a short extent of territory and terminate in flattened or globular extremities, the number seldom exceeding six or eight (Fig 2).

The terminations from the collaterals of the psychical cells show a very different disposition. Winding among the dendrites of the cells and often closely applied to them they seldom show any definite endings until the mid portion of the layer of small pyramidal cells is reached. There they split up into a number of exceedingly fine branches, which frequently run parallel with the course pursued by the apical and basal dendrites. They eventually give off at frequent intervals exceedingly short collaterals, usually from the side nearest to the dendrites, which terminate in a round or flattened bulb like extremity similar to those on the branches of the ascending fibres. These are closely applied to the bulbous tip of the gemmules, the appearance often suggesting one of actual contact, the axonal discharges of the stimuli overleaping the infinitesimal distance between the bulb and gemmule (Fig 1). "The interpretation of the objective existence of the terminal apparatus of the nerve fibres," Berkley says, "cannot be made but in one way—namely, that the impressions conveyed from external sources to central cell and from local cell to local cell are not accomplished by a diffusion of the excitation through the whole cortex, or even at various points along the course of the finer branches of the axons, but at single points perfectly definite in their distribution, and that these points are situated only at the extremities of the nerve-fibre twigs, in the form of an histologically exact formation—the bulbous ending of the nerve fibre—which in itself constitutes the sole and only means for the carrying over of the cellular forces from axon to dendron and from cell to cell, and is in entire conformity with the conception of Waldeyer of the entity of the neuron, each cell standing as a unit in the nervous formation and only in continuity with others at definite points." In a still more recent communication Lugaro also states that the transmission of impulses occurs through the extremity of the gemmules. These he believes are capable of expansion and retraction to a slight degree, and upon this function he bases his theory, which I shall presently allude to, of psychical processes. A form of nerve termination in the central nervous system has been described by Aldren Turner and Hunter in the Spring number of *Brain* for 1899, but so far this has not been utilised to explain sleep. After injecting methylene-blue into the circulation during life they found after death a fine lattice-work arrangement over the cells in most parts of the brain. This was most marked over the root of the axis cylinder process and according to these authors it is the termination of the axis cylinder of another cell. There is no continuity of tissue and therefore the entity of the neuron is not questioned. Nerve impulses are believed to pass from the network to the cell body and not from terminal axite to dendrite, or *vice versa*. The function of the dendritic processes, the authors are inclined to believe, is nutritive—a theory first suggested by Golgi.

After this brief survey of the place of the neuron in nerve-physiology we shall be better able to understand some of the theories which have been put forward to explain sleep. But before dealing with these it will be well to review the facts which it is necessary to explain. Speaking generally, during sleep the whole metabolism of the body is depressed. The respirations are shallower, the aeration of the blood is less active, the pulse is less frequent, the blood pressure is lower and the temperature tends to fall, the nervous system

is so affected that sense stimuli of moderate intensity are not perceived, and consciousness is in abeyance, but reflex effects can still be obtained. These phenomena are not constant during the sleeping state, but vary within fairly wide limits. On this account some of them have been credited with an etiological rôle, and this leads us on to the

THEORIES OF SLEEP

Those advanced up to the present time may be divided into chemical, histological, vaso-motorial, and psychological. These theories are not necessarily antagonistic, as we shall presently see, but their promulgators differ in their mode of explanation and in the prominence which they give to an individual character. Let us first consider the cause of sleep in the abstract.

It is evident that consciousness, whatever this may be, is due to a certain definite condition of the nerve-cells or neurons and any departure from complete consciousness must be due to some change from this state. At the present time it is difficult to come to any other conclusion than that this state and its alterations are of a chemical nature—that consciousness is accompanied by, if not due to, a normal metabolism of the nervous cells, and unconsciousness or diminished consciousness to a chemical alteration in this metabolism. This so-called normal metabolism is the result not merely of the vital requirements of the cells but of this *plus* the alterations produced by the inflow of stimuli. Diminish the stimuli or make them constant both as to kind and intensity (monotony) and the metabolism may become constant though in changed conditions, a kind of rapid acclimatisation occurs, and with it diminished consciousness. The same effect might be produced by the alteration of metabolism due to the application of a poison. It seems to me that the fundamental phenomena to be determined in dealing with psychical processes are the chemical changes occurring in the cells, molecular vibration and processes of a similar nature which have been speculated upon from time to time are, with our present knowledge, in the realms of the unknown. Even if they can be known it seems more philosophical to determine the gross chemical changes first, although there is not much likelihood of these being actually demonstrated in the near future. Admitting that chemical alterations are the causes or proportional concomitants of states of consciousness we shall be able to trace a connexion in some of the various theories of sleep which have been propounded. Thus, it is very evident that the metabolism of the cerebral cell may be and probably will be altered by, changed extrinsic conditions—e.g., by the blood supply—and that it may produce gross physical changes in the cell—e.g., retraction of the protoplasmic processes. The vaso-motorial and histological and in part the chemical theories are—or perhaps it would be better to say may be—thus brought into connexion. But let us examine the theories in detail.

The most fascinating of them all is what Duval has termed the *histological theory* of sleep. This seems to have been propounded in its most rudimentary state by Rabi Rückhard who suggested that an assumed amoeboid motion of the neurons, and especially the dendritic processes, would account for various psychological phenomena. Thus sleep might be explained by a retraction of these processes and consequent inability of nervous impulses to pass from one neuron to another. The same theory was elaborated independently by Lépine and Duval. Lépine thinks this isolation of the individual neurons may be due to some chemical modification of the cellular protoplasm and he also states that the theory explains the extraordinary suddenness with which a state of wakefulness passes into one of sleep. Duval goes so far as to explain the action of medicaments on this theory and he draws comparisons between the action of drugs on the terminal dendritic processes and the effect of curare on motor nerve endings. This is surely hypothetical. Moreover, he seems to ignore the body of the cell itself, everything is referred to the dendritic terminations. It is most unnecessary to point out that the theory of Rabi Rückhard, Lépine, and Duval is dependent upon the conception of isolated neurons as independent units in the composition of the nervous system and that with the disproof of this conception their theory must fall to the ground. Kölliker has strongly criticised this (the amoeboid movement) theory. He says that Widdersheim's observations on the movements occurring in the nerve cells of the supra-oesophageal ganglion of *Leptodora hyalina* are not pertinent to the question, and he rejects

this view the transmission of nervous impulses presents no obstacle. Another theory of the function of these gemmules and the transmission of impulses has been put forward by Berkley. He accepts the knob-like terminations of the gemmules as natural, but he cannot accept Ramón y Cajal's theory that nervous forces may discharge themselves from axites to dendrites all along the line. The dendrites he believes, are covered with a thin enveloping sheath through which the gemmules penetrate, and it is only at the tip of the gemmules that naked protoplasm exists. Similarly the fine branches of the axites are covered with "a protective sheath of great tenuity" and only exhibit naked protoplasm at their bulbous terminations. Therefore Berkley believes that it is only between these free terminations that nerve impulses can pass. The mode of branching of the axites varies according as they form ascending fibres (extrinsic) or belong to local cells (intrinsic). The extrinsic break up into a number of filaments, usually at some distance from one another, which re divide into a small number of others. These course over a short extent of territory and terminate in flattened or globular extremities, the number seldom exceeding six or eight (Fig 2).

The terminations from the collaterals of the psychical cells show a very different disposition. Winding among the dendrites of the cells and often closely applied to them they seldom show any definite endings until the mid portion of the layer of small pyramidal cells is reached. There they split up into a number of exceedingly fine branches, which frequently run parallel with the course pursued by the apical and basal dendrites. They eventually give off at frequent intervals exceedingly short collaterals, usually from the side nearest to the dendrites, which terminate in a round or flattened bulb like extremity similar to those on the branches of the ascending fibres. These are closely applied to the bulbous tip of the gemmules, the appearance often suggesting one of actual contact, the axonal discharges of the stimuli overleaping the infinitesimal distance between the bulb and gemmule (Fig 1). "The interpretation of the objective existence of the terminal apparatus of the nerve fibres," Berkley says, "cannot be made but in one way—namely, that the impressions conveyed from external sources to central cell and from local cell to local cell are not accomplished by a diffusion of the excitation through the whole cortex, or even at various points along the course of the finer branches of the axons, but at single points perfectly definite in their distribution, and that these points are situated only at the extremities of the nerve fibre twigs, in the form of an histologically exact formation—the bulbous ending of the nerve fibre—which in itself constitutes the sole and only means for the carrying over of the cellular forces from axon to dendron and from cell to cell, and is in entire conformity with the conception of Waldeyer of the entity of the neuron, each cell standing as a unit in the nervous formation and only in continuity with others at definite points." In a still more recent communication Lugaro also states that the transmission of impulses occurs through the extremity of the gemmules. These he believes are capable of expansion and retraction to a slight degree, and upon this function he bases his theory, which I shall presently allude to, of psychical processes. A form of nerve termination in the central nervous system has been described by Aldren Turner and Hunter in the Spring number of *Brain* for 1899, but so far this has not been utilised to explain sleep. After injecting methylene-blue into the circulation during life they found after death a fine lattice-work arrangement over the cells in most parts of the brain. This was most marked over the root of the axis cylinder process and according to these authors it is the termination of the axis cylinder of another cell. There is no continuity of tissue and therefore the entity of the neuron is not questioned. Nerve impulses are believed to pass from the network to the cell body and not from terminal axite to dendrite, or *vice versa*. The function of the dendritic processes, the authors are inclined to believe, is nutritive—a theory first suggested by Golgi.

After this brief survey of the place of the neuron in neurophysiology we shall be better able to understand some of the theories which have been put forward to explain sleep. But before dealing with these it will be well to review the facts which it is necessary to explain. Speaking generally, during sleep the whole metabolism of the body is depressed. The respirations are shallower, the aeration of the blood is less active, the pulse is less frequent, the blood pressure is lower and the temperature tends to fall, the nervous system

is so affected that sense stimuli of moderate intensity are not perceived, and consciousness is in abeyance, but reflex effects can still be obtained. These phenomena are not constant during the sleeping state, but vary within fairly wide limits. On this account some of them have been credited with an etiological rôle, and this leads us on to the

THEORIES OF SLEEP

Those advanced up to the present time may be divided into chemical, histological, vaso-motorial, and psychological. These theories are not necessarily antagonistic, as we shall presently see, but their promulgators differ in their mode of explanation and in the prominence which they give to an individual character. Let us first consider the cause of sleep in the abstract.

It is evident that consciousness, whatever this may be, is due to a certain definite condition of the nerve-cells or neurons and any departure from complete consciousness must be due to some change from this state. At the present time it is difficult to come to any other conclusion than that this state and its alterations are of a chemical nature—that consciousness is accompanied by if not due to, a normal metabolism of the nervous cells, and unconsciousness or diminished consciousness to a chemical alteration in this metabolism. This so-called normal metabolism is the result not merely of the vital requirements of the cells but of this *plus* the alterations produced by the inflow of stimuli. Diminish the stimuli or make them constant both as to kind and intensity (monotony) and the metabolism may become constant though in changed conditions, a kind of rapid acclimatisation occurs, and with it diminished consciousness. The same effect might be produced by the alteration of metabolism due to the application of a poison. It seems to me that the fundamental phenomena to be determined in dealing with psychical processes are the chemical changes occurring in the cells, molecular vibration and processes of a similar nature which have been speculated upon from time to time are, with our present knowledge, in the realms of the unknown. Even if they can be known it seems more philosophical to determine the gross chemical changes first, although there is not much likelihood of these being actually demonstrated in the near future. Admitting that chemical alterations are the causes or proportional concomitants of states of consciousness we shall be able to trace a connexion in some of the various theories of sleep which have been propounded. Thus, it is very evident that the metabolism of the cerebral cell may be and probably will be altered by, changed extrinsic conditions—e.g., by the blood supply—and that it may produce gross physical changes in the cell—e.g., retraction of the protoplasmic processes. The vaso motorial and histological and in part the chemical theories are—or perhaps it would be better to say may be—thus brought into connexion. But let us examine the theories in detail.

The most fascinating of them all is what Duval has termed the *histological theory* of sleep. This seems to have been propounded in its most rudimentary state by Rabl Rückhard who suggested that an assumed amoeboid motion of the neurons, and especially the dendritic processes, would account for various psychological phenomena. Thus sleep might be explained by a retraction of these processes and consequent inability of nervous impulses to pass from one neuron to another. The same theory was elaborated independently by Lépine and Duval. Lépine thinks this isolation of the individual neurons may be due to some chemical modification of the cellular protoplasm and he also states that the theory explains the extraordinary suddenness with which a state of wakefulness passes into one of sleep. Duval goes so far as to explain the action of medicaments on this theory and he draws comparisons between the action of drugs on the terminal dendritic processes and the effect of curare on motor nerve endings. This is surely hypothetical. Moreover, he seems to ignore the body of the cell itself, everything is referred to the dendritic terminations. It is most unnecessary to point out that the theory of Rabl Rückhard, Lépine and Duval is dependent upon the conception of isolated neurons as independent units in the composition of the nervous system and that with the disproof of this conception their theory must fall to the ground. Kölliker has strongly criticised this (the amoeboid movement) theory. He says that Widersheim's observations on the movements occurring in the nerve cells of the supra-oesophageal ganglion of *Leptodora hyalina* are not pertinent to the question, and he rejects

FIG 3

has advanced a modified form of the vaso-motor theory based upon personal experiments. According to him the anæmia of the cortex is counterbalanced by the dilatation of the vessels at the base of the brain. The causal factor of sleep is a fatigue of the vaso motor centre and particularly of that part of it supplying the skin area. This Professor Howell deduces from the fact that the volume of the arm increases (that is, the cutaneous blood vessels dilate) just previously to sleep, and it usually contracts suddenly on awaking. He does not, however, ascribe the production of sleep solely to the fall of blood pressure, but he regards this as pre-eminent. The etiological factors he gives as follows: 1. A diminution of irritability caused by fatigue of large portions of the cortical area. 2. Voluntary withdrawal of sensory and mental stimuli involved in the preparations for sleep. 3. A diminished blood supply to the brain owing to a relaxation of tone in the vaso motor centres and the fall of general arterial pressure thereby produced. Recently Dr Leonard Hill has criticised Professor Howell's results, or rather his deductions from his results. He finds that the fall of arterial pressure is concomitant with sleep and he adduces confirmatory experiments. Thus he found arterial pressure "as low when lying in bed in the waking state in the morning as in the sleepy state in the evening"—a result evidently antagonistic to Professor Howell's theory. Moreover, it is not difficult to explain the fall of blood pressure during sleep, or even previously to sleep, by the posture, the diminution of external stimuli, the extra clothing, &c., which we seek before endeavouring to sleep. The rapid rise of blood pressure at the moment of awaking Dr Leonard Hill explains thus: "As the waking state is neared the turgescence of the limbs is lessened owing to the increased tone of the muscles and to the restlessness of the sleeper. Each movement or deep respiration expresses the blood and produces a lessening in the volume of the arm. This is shown to be so by an examination of Howell's tracings. Since each movement of the body momentarily raises the vena cava pressure the brain is congested thereby, for the cerebral circulation passively follows every change in vena-cava pressure. The flushing of the brain is secondary to the external stimuli which provoke the external movements of the body, accelerate the heart, and increase the vaso motor tone. At the same time these stimuli may awaken the dormant consciousness. Carefully reviewing all the above facts we must, I think, conclude that the anæmia of the brain is caused by rest of the body and the cessation of powerful objective and subjective stimuli. It is the cessation of the latter that produces sleep."

As regards the fall of arterial pressure being *post* or *propter* I agree with Dr Leonard Hill that it is the former. The vaso-motor theory of sleep is quite inadequate to explain this condition, nevertheless, vascular phenomena play a part, and an important part, in sleep production. What, then, is the probable condition of the cerebral vessels in sleep? We have seen that the brain is a closed cavity, that the general arterial pressure falls during sleep, and that the pressure in the intra cranial veins varies absolutely with that of the intra thoracic venous pressure, and it may be further stated that the intra-cerebral blood vessels have not been shown to possess any vaso-motor innervation. It follows from these and other facts that the arteriole pressure is dependent on the venous pressure and that any diminution in the size of the arterioles must be replaced by increase in size of the veins or other cerebral vessels. Professor Howell believes that the basal vessels dilate, but I am more inclined to agree with Crippie who attributes the greater action to the pial vessels, probably both sets of vessels are involved. But the condition during sleep, it seems to me, is rather one of comparative blood stasis than of simple anæmia. In either case a smaller amount of blood passes through the cerebral vessels in a given interval of time and this is in reality the essential factor. And although I cannot regard a fall in blood pressure as the primary causal factor of sleep, yet the diminished supply of nutriment thus produced must exert a depressing influence on the metabolism of the cerebral cells and aid in sustaining, if not in inducing, sleep. That the fall of arterial pressure is not necessary is shown by the action of many hypnotics, which directly exert no influence in this direction, but it may also be said that, other things being fairly equal, those hypnotics which depress blood pressure are more certain sleep-producers than those which do not. Chloral, for example, is more certain than any of its derivatives. Indeed, it seems to me that the evidence of pharmacology in dealing with the various theories of sleep has been too much neglected. Perhaps it

has not much to give, but at least it may help in correcting theories framed on other and different lines. The admissibility of pharmacological evidence naturally raises the question as to whether forced sleep from drugs is comparable to natural sleep. Although some hold to the contrary I am inclined to believe that it is. The restorative effect of a properly apportioned dose of a hypnotic in a mild case of insomnia is suggestive. Moreover if we accept the idea that sleep is the result of chemical changes in the cerebral cells this conception gains in force, as the introduction of a hypnotic into the organism merely means a change in the environment of the cell with subsequent variation in its activity. To deduce from the narcosis produced by large doses of these drugs that artificially produced and natural sleep are dissimilar is unfair, in this case the stimulus is excessive and the result not comparable. But to return to the theories of sleep.

The various chemical theories which have been put forward seem to have been based on insufficient data. With the older theories of Sommer and Pfüger and others I do not intend to deal. But comparatively recently a new chemical theory has been advanced. Errera believes that the leucomaines produced by the normal activity of the body play a predominant part. He has based his view mainly on the experiments of Bouchard and his school, who found that during the night convulsant substances were excreted in the urine which were not present during the day. The toxicity of the urine during sleep was found to be much less than that of the urine passed whilst awake. On these experiments Bouchard formulated the theory that during the day the body formed a hypnotic substance which by its accumulation produced sleep and that during sleep a convulsant substance was formed which by inducing muscular movements produced awakening. Both Beck and Herringham have failed to corroborate Bouchard's experiments, but apart from this it is difficult from evidence of this kind to draw conclusions as to the cause of sleep. The urine is a complex body, it varies largely in composition with the kind of food, the amount of exercise, and other physiological and pathological conditions, and this variation is greater with this than with other secretions. It does not seem right to compare the variability of the composition of the urine with the periodic alterations in the temperature and pulse, the limits of the first are much wider. Furthermore, as in the case of blood pressure, it does not seem to me proved that this altered composition of the urine is not *post* rather than *propter*. I do not mean to imply that metabolic changes have no influence in the production of sleep, but what I do maintain is that sleep has not been proved to be due to any one substance or group of substances present in the urine. The chemical theory from another point of view I shall mention presently.

The fourth class of our division of the theories of sleep is the *psychological*. And here we enter upon difficult ground. We have seen that the physiological and psychological are two separate spheres with independent methods of analysis, that the elements of the two sciences are different, and that the connexion between the two can only be one of parallelism. It may be that we shall never get beyond this stage—that the physical and the psychical even in their simplest forms are not comparable, but from a physiological point of view there seems nothing improbable in the idea that they may be correlated. Marie de Manacéine, in a popular book on sleep published two years ago, defines sleep as "the resting time of consciousness."

A Discourse

ON

PREVENTIVE INOCULATION,

Delivered at the Royal Society, London, on June 8th, 1899,

By W M HAFKINE, CIE,

BACTERIOLOGICAL RESEARCH OFFICER TO THE INDIAN GOVERNMENT

MR PRESIDENT AND GENTLEMEN,—The most important modern methods of prophylactic treatment are based upon the fact that an attack of disease from which an individual recovers leaves in him a condition of resistance to another attack. The possibility of turning to advantage this fact was first demonstrated to us by Mahomedan physicians to whom the world thus owes the knowledge of what proved to be one of the most fertile principles of modern science. The successes of Jenner and Pasteur, who utilised cultivated virus for preventive treatment, have led to a general conception that there is the possibility of creating artificial immunity to diseases by treating the organism with morbid products rendered by some special means harmless. This definition involves a generalisation which led to a considerable amount of disappointment, as the application of the principle in a number of instances did not give the expected results.

DERIVATES FROM MICROBIAL VIRUS AND THEIR EFFECT

When we cultivate a pathogenic micro-organism in a liquid medium two different elements are obtained mixed together the bodies of the microbe and the liquid which it has modified and into which it has secreted its own products. A modification of the entire preparation, as represented by this mixture, can be first of all obtained by filtering the two elements just mentioned and considering each of them by itself, or else the two can be left together and only the vitality of the microbe destroyed by some physical or chemical agent, or the constitution and the properties of each or of both of these elements can be to a desired degree altered by the admixture of chemicals or by subjecting them to physical processes, or else the vital and pathogenic properties of the microbe can be modified by artificial breeding, and then the microbe itself or the products of such a modified microbe used for treatment. The immediate effect which a given virus or its derivate produces on an animal differs with the kind of virus taken, the process of modification to which it has been subjected, and the species of animal upon which it is used. The following instance may give an idea of these variations.

The ordinary Indian grey as well as the brown monkey are susceptible to the plague virus and may contract a fatal disease from being simply pricked with an infected needle. The rabbit and guinea pig are also susceptible to the disease. The horse, on the contrary, contracts no fatal disease after being infected even with large doses of the living virus. If, however, a plague culture be heated and the microbes killed in it the relations between the monkey and the horse seem to become the reverse of the former, the guinea pig remains comparable with the monkey, while

the rabbit shares with the horse the susceptibility which it shared first with the monkey. It will require, according to several observers, a very large dose of such treated virus to produce in the monkey or in the guinea pig any marked rise of temperature or any alteration of the skin at the seat of injection, while the horse answers to the injection by almost as brisk an attack of fever as if the virus were a living one, and at the seat of inoculation a tumour is produced which, if the dose be at all considerable, may lead to a complete mortification of the tissue. The rabbit similarly answers to the injection by an attack of fever and by the formation of a hard tumour at the seat of injection.

As varied as is the immediate effect of different forms of virus upon different animals, so varied is the result of the application of such virus from the point of view of immunity conferred by it. There are animals in which the inoculation leaves no lasting effect whatever. In others a very temporary immunity is created, vanishing away in a few days. In other cases, again, a condition appears that produces the impression as if after the treatment the animal has become more susceptible to a subsequent infection than is a normal, not so treated animal. And, lastly, there may be found animals in which the same virus will produce a great and long lasting immunity. In general I believe it to be admissible that in the case of every disease and with regard to every species of animals a form of treatment may be found that will produce immunity against disease in that particular case, but the same method of treatment may or may not be applicable to another animal or to another disease affecting the same animal. It is the not taking into account of this variation of circumstances that I believe more than anything else has checked the success of a number of experimenters.

IMMUNITY AGAINST ATTACK AND RESISTANCE AGAINST THE ACTUAL SYMPTOMS OF THE DISEASE

The study of the anti cholera inoculation in India has revealed a new problem in the subject of prophylactic treatment. The particular character of cholera epidemics which appear unexpectedly, do not last, and in places where they are permanent are spread and scattered over large areas makes the study of that disease and the demonstration of the effect of a preventive treatment in its case a matter of much greater difficulty than is the case in localised contagious diseases like small pox or in plague, and although a large amount of material has been collected already it is desirable that a number of observations be added to the presents ones confirmatory of the results obtained. The information collected permits, however, already of pointing out very important features in the working of the anti cholera inoculation. The most extended and continuous observations on the subject were organised by the municipality of Calcutta upon the enlightened initiative of Dr W J Simpson and under his continuous supervision as well as my own. These observations refer to the cholera stricken suburbs of Calcutta, the so-called "busties" or groups of huts situated round the tanks where rain water is collected during the monsoon. Some 8000 people were inoculated in those localities and for two years observations were made and the results collected as to the occurrences of cholera in the huts inhabited by the inoculated. In the vast majority of cases there lived in the same families members who had not been inoculated together with others inoculated and the possibility thus presented itself of comparing the incidence of the disease in individuals of the same households, exposed as much as is possible to the same chances of infection.

During the time under observation cases of cholera occurred in 77 huts. As a result of careful investigation of these cases it was seen that for a period of 738 days cases of cholera occurred among the uninoculated at all intervals after the date of inoculation, whereas the figures referring to the inoculated showed a striking variation of the incidence when compared at various distances from the time of inoculation. Cases continued to occur among the inoculated for a period of four days after the treatment and then for 416 days the inoculated practically remained free from the disease, only one death having occurred among them during that time. From the 421st day up to the end of the observation six cases occurred among them again. The

THE PROPERTIES OF THE PLAGUE PROPHYLACTIC

The immunising effect of the plague prophylactic as above described was worked out on domestic rabbits and its actual efficiency on these animals was since verified and confirmed by a number of experimenters by trying to infect with virulent plague protected and unprotected animals. Comparing the rabbit with other laboratory animals, such as the rat, the guinea pig, the mouse, and the monkey, one may consider the rabbit as the one that perhaps required the least amount of protection, as its natural resistance to plague is relatively high. The most altered virus—i.e., such as was rendered the most harmless of all—was found to confer on the rabbit a very considerable degree of immunity, enabling it in a few days to resist ten or fifteen fold lethal doses of virulent plague microbes. The same treatment applied to animals of a more susceptible nature would, on the contrary, in many instances fail.

THE QUESTIONS WHICH WERE TO BE SOLVED BY EXPERIMENTS ON HUMAN BEINGS

At the end of our laboratory experiments a very definite set of questions stood before us, which were to be solved by direct experiment on human beings. Those questions were: 1. Would man behave with regard to the prophylactic like the animals upon whom its protective power had been worked out? 2. If it so happens that the answer is affirmative, what would the dose of the prophylactic and the method of administering it be, and would not the dose required be so high, and the reaction to be produced so severe, or the number of inoculations to be repeated so great, as to render the treatment inapplicable to men or impracticable? 3. How many days counting from the date of inoculation would it take to produce in man a useful degree of immunity? 4. How long would that immunity last? And lastly, there followed two questions, to which my experience of the anti-cholera inoculation entitled me to give a reassuring answer, but which it was necessary to verify in plague again, viz: 5. During the period of reactionary fever and all the other symptoms produced by inoculation, will the resistance of the inoculated exposed to plague be, for the time being, reduced, or remain the same, or be increased—i.e., would it constitute a danger to apply the inoculation in localities actually affected with plague? and 6. When a man who happens to be incubating the plague, or to have initial symptoms of the disease already, chances to be inoculated, would it aggravate his condition, or have no effect, or, on the contrary, help him?

DEMONSTRATION OF THE HARMLESSNESS OF THE INOCULATION

The perfect harmlessness of the inoculation was first of all demonstrated by the officers of the laboratory, the principal and professors of the Grant Medical College, a large number of leading European and native gentlemen of Bombay, and their families and households being inoculated, and after that when, in the last week of January, 1897, the plague broke out in Her Majesty's House of Correction at Byculla, in Bombay, the option of inoculation was offered to the prisoners.

THE EXPERIMENT IN HER MAJESTY'S BYCULLA HOUSE OF CORRECTION, BOMBAY

The Byculla Jail is a long term one. There are no children or very young people among the inmates, there being in Bombay a separate establishment, the Sassoon Reformatory, where minor criminals are sent. The prisoners of the House of Correction present a well fed, well clad, regularly worked, and almost as uniform a set of people as can be seen in a regiment, amongst whom one could scarcely see a single infirm or very aged individual. At the appearance of plague the prisoners numbered 346. The inoculation was introduced after nine cases of plague had already occurred, five subsequently ending fatally, there remained thus 337 individuals to be dealt with. Of these, 154 only volunteered for inoculation and 183 remained uninoculated. On Jan 30th, in the forenoon, before the inoculation was applied, six more cases occurred of which three afterwards proved fatal. The inoculation was applied in the afternoon, and afterwards it was discovered that one more prisoner had already a bubo on him when inoculated, while two prisoners developed buboes in the same evening after their inoculation. These three inoculated, attacked in the evening of inoculation, proved also fatal. After that the difference observed in

the fate of the two groups, the inoculated and uninoculated, is seen from the subjoined table—

Date of occurrence of plague	Occurrences in uninoculated.			Occurrences in inoculated.		
	Number of uninoculated present.	Cases.	Fatal.	Number of inoculated present.	Cases.	Fatal.
Jan. 23rd to 29th 1897 previously to the day of inoculation	—	9	5	—	—	—
30/1/97, the day of inoculation	Fore noon before inoculation	—	6	—	—	—
		—	3	—	—	—
	After noon, after inoculation	—	—	—	3	3
		—	—	—	—	—
First day after inoculation 31/1/97	177	2	1	151	1	—
Second day after inoculation, 1/2/97	172	1	1	150	—	—
Third day after inoculation, 2/2/97	173	1	1	146	—	—
Fifth day after inoculation 4/2/97	171	1	1	146	—	—
Sixth day after inoculation, 5/2/97	169	2	1	146	—	—
Seventh day after inoculation 6/2/97	169	5	1	146	1	—
Total after the day of inoculation	172 uninoculated, average daily strength.	12 cases.	6 deaths.	147 inoculated, average daily strength.	2 cases.	No deaths.

For seven days, except the fourth, after inoculation cases of plague continued to occur among the uninoculated group, their average daily strength throughout the week being 173; altogether, 12 cases occurred among them with six deaths; while in the 148 inoculated there was one case on the next day after inoculation which rapidly recovered and one on the last day of the epidemic which recovered also.

ANALYSIS OF THE RESULTS OF THE BYCULLA JAIL EXPERIMENT

A glance at the above table will show the progress which was made in our information by that initial experiment and how far it carried us ahead from the state of uncertainty which surrounded the question originally. The dose of prophylactic administered to the prisoners was three cubic centimetres. They all had the customary attack of fever from the operation, with the discomfort accompanying that condition—a headache in many cases, nausea, loss of appetite for a couple of days, a feeling of fatigue and lassitude, reminding one of a mild attack of influenza, and with swelling and pain in the inoculated side. Did, however, all this make them more susceptible to the disease than were their non inoculated fellow inmates? It is certain that the table testified unmistakably to an opposite result. Further, the incubation period in plague appears to be on the average five days, extending, however, not unfrequently up to 10. Of the 12 prisoners in the uninoculated group who developed plague during the next few days after the date of inoculation a large proportion, if not all, must have been already incubating the disease on that day, and seeing the perfect similarity of conditions under which the inoculated and the uninoculated, who came from the same crowd of people, were living one could infer safely that a similar group of individuals incubating plague was present among the inoculated also at the time when the inoculation was performed on them. The inoculation, however, did not aggravate their condition, as the number of inoculated who developed plague, counting from the first twelve hours of inoculation, was proportionately five times smaller than the corresponding number among the uninoculated, and the two cases that appeared among the inoculated, one on the very next morning after inoculation, both ended in recovery. As far as that first experiment went, therefore, men behaved like the laboratory animals which derived protection from the inoculation. For communicating that protection one injection of prophylactic appeared sufficient with a dose of three cubic centimetres,

numbering some 10,000 to 12,000 people, where about half of the total number were inoculated under the auspices of His Highness the Aga Khan. A most comprehensive inoculation campaign and with widely reaching and most satisfactory results was carried out under the Collector of Dharwar by Captain Leumann, I.M.S., Dr (Miss) Corthorn, Dr Hornabrook, Dr Foy, Dr Chenai, and others in the three adjacent small towns of Hubli, Dharwar, and Gadag, where some 80,000 people were inoculated. The latter was the most magnificent piece of work done, from the point of view of practical application of the method. With the extension of the number of inoculated the exactitude and precision of observation must, however, suffer.

A number of doubts and possible objections with regard to many particular points arise which it is not always possible to answer with certainty. Such observations are required to enable us to judge whether the application of the method as a general measure answers to the expectations formed, but the exact extent of the results is to be gathered from such mathematically precise experiments, imitating the conditions of laboratory practice, as were those which I have detailed above. The difference in the mortality from plague between inoculated and uninoculated parts of communities was estimated to average over 80 per cent, approaching often 90, as was the case in Undhera the lowest proportion ever observed in the experiments which I made personally having been 77.9 per cent. This was at Kirkee.

CASE MORTALITY REDUCED BY 50 PER CENT

A very accurate set of data were collected in almost all the larger hospitals where inoculated plague cases were admitted upon the fatality of the disease in the inoculated. These were to the effect that the case mortality among the inoculated was some 50 per cent lower than among the uninoculated plague cases. A number of documents on this point have been collected by the Indian Plague Commission and will appear, I trust, in their records.

MINIMUM DURATION OF THE EFFECT OF THE PLAGUE INOCULATION

As to the duration of the effect of the plague inoculation the statement which can be made for the present is that it lasts at least for the length of one epidemic, which on the average extends from over four to six months of the year. The Government of India have recognised the inoculation certificates, entitling the holder to exemption from plague rules, to be valid for a period of six months, with the understanding that if accurate data are forthcoming of the effect lasting longer the holders will be permitted to exchange their certificates for another period without being re-inoculated.

THE FURTHER PROBLEMS PURSUED IN THE BOMBAY PLAGUE RESEARCH LABORATORY

The task which the officers of the Bombay Plague Research Laboratory have proposed to themselves in connexion with the prophylactic inoculation comprises now the following problems: (1) the working out of proceedings for turning out uniformly large quantities of material and avoiding the variations due to the character of the plague microbe and to the differences in the composition of the cultivation media, (2) the further investigation of the different constituents of the plague prophylactic with a view of enforcing those which produce definite and beneficial results, (3) the possible mitigation of the reactionary symptoms after inoculation, and (4) the study of the effect of antiseptics used for preserving the prophylactic, while their most important general problems concerning plague refer to the study of the curative treatment of plague and to the life history of the plague microbes in nature.

THE TYPHOID INOCULATION

Permit me now to enter a pledge in favour of a new inoculation campaign which has been inaugurated already and which I hope will be carried out successfully for the benefit of a large number of soldiers of this country residing in India. The number of white men in general in all tropical countries. The problem of typhoid inoculation has quite a special interest for Europeans as much as cholera has for the natives of India. Typhoid fever proved to be a more difficult disease to eradicate from military cantonments than cholera. It is possible that the explanation of that lies in what is already

known of the character of the microbes of these diseases. The typhoid bacillus when subjected to different chemical and physical agents, such as acids or antiseptics, or a high temperature, or desiccation, or the admixture of other microbes, appears far more resistant than the cholera microbe. Such a character would ensure for the typhoid bacillus the existence in more varied media under more various climates and a greater independence from seasonal or local changes than is the case with the cholera microbe. Outside the endemic area the cholera remains in one and the same place for a few weeks and in any given part of a town often for a few days only. It is rare that it visits one and the same barrack more than once in five years, sometimes ten years, and when it occurs a temporary evacuation of the place puts a stop to the disease. The typhoid virus, on the contrary, sticks to an infected locality for years and causes a continuous incidence of the disease, for which occasionally nothing short of a complete desertion of the station is effective. At the same time, while the cholera infection seems to be almost exclusively confined to the water supply, in typhoid fever the improvement of the water seems to leave intact a large number of other sources of danger which up to the present time have escaped recognition. Differing thus in their life-history in nature, the bacilli of cholera and typhoid fever present important common features in the manner in which they behave in the human and animal body. The chief centre of infection in both instances is the intestinal canal, the circulatory system remaining free from invasion. When inoculated into animals both microbes admit of the same kind of transformation by passages from animal to animal, and against both immunity can be created in the laboratory by the same preparation of virus as used in the inoculations for cholera, while when examining the tissues of immunised animals the same modifications are detected in them as those observed after the anti-cholera inoculation. These considerations have led us to expect from the typhoid inoculation in man a similar protective effect as that observed in the inoculation against cholera, and seeing that the period of life during which the new comers to India remain susceptible to typhoid fever extends only over a few years it seems that the application of the system, when properly organised, is likely to prove of a very high practical value.

INOCULATION AND GENERAL SANITARY MEASURES

The anti-cholera inoculation, the inoculation against plague and that against typhoid fever came to associate themselves to vaccination and represent attempts at dealing with epidemics on lines differing from measures of general sanitation. During the last few years the question was therefore frequently debated as to the relation in which the two stand to each other. It is scarcely necessary to say that inoculation cannot be substituted for a good water supply, the draining, cleansing or improvements in the building of cities, or for the admission of a larger amount of light and air into overcrowded localities, for all those measures to which the nations owe such a wonderful improvement in health as has taken place during the present century. Only justice would be done to the sanitarian by calling him in when a patient lies already on his sick bed or when an epidemic actually breaks out in a community, and by asking him to stay the sickness or the epidemic, to improve the health of the population, so to say, while you wait. Epidemics, like individual diseases, require specifics, promptly administrable remedies, to be dealt with, and measures of general sanitation can be no more advised for arresting an outbreak of cholera or plague than can an individual patient be directed to build for himself a new house, or to dry up the marshy lands, or to cut down the jungle round his habitation when he requires a dose of quinine to arrest an attack of fever. The part of vaccination and of preventive inoculation in combating epidemics stands in the same relation to general sanitary measures as therapeutics and the art of the healing physician do to domestic hygiene. It is certain that neither of these can ever be substituted for the other.

INOCULATION AND THE SEGREGATION DISINFECTION METHOD

A comparison of a different kind now very actively discussed is that between the methods of combating epidemics by separation of sick and healthy and disinfection on the one hand and by preventive inoculation of the people on

tuberculous, syphilitic, and cerebro-spinal fever. An etiological classification, possible to-day in part, is of necessity incomplete. In the annexed diagram I have made a provisional grouping of the chief forms —

The acute primary lepto-meningitis in a large proportion of all cases follows an infection with the diplococcus intracellularis or the pneumococcus. It will be a great gain if Still's observations (to which I shall refer later) on the posterior meningitis are confirmed. I do not know where Quincke's meningitis should come in an etiological grouping. The secondary forms of meningitis in the table I shall not refer except to call attention to the importance of the pneumococcus in this group also, nor can I discuss within the limits of this lecture the clinical features or the varieties of meningitis, and must confine my remarks to a few special points in the diagnosis or cerebro-spinal fever and to a consideration of certain sporadic forms of meningitis.

1. Certain features in the symptomatology of cerebro spinal

CHART I, CASE 7

No other form of meningitis presents a symptomatology of the same fulness—general, cerebral, spinal, and peripheral features are present in almost every case. This results in part from the extent of the cerebro-spinal involvement, in part from the very frequent implication of the nerves, and to some degree is a consequence of the very chronic course. I shall discuss only a few of the important (a) Onset.—In striking contrast to other forms, particularly the tuberculous, cerebro-spinal fever sets in abruptly. Without warning, while at work, or awakening the patient from a sound sleep, comes the pain in the head, &c. This peculiarity may also be met with in primary pneumococcal meningitis, but in the form secondary to pneumonia and in that which arises in endocarditis latency of onset is the rule. (b) Fever.—There is no constant type of fever in any form of meningitis. In cerebro-spinal fever, the pyrexia is very variable and I have given here a few charts in illustration. There may be no fever at onset—as shown in Charts VIII. and IX. of the sporadic cases. Of our epidemic cases all had fever on admission. Irregularity in the fever may be present from the start. There is not a steady rise at first to a height, but even on the third or fourth day the temperature may fall to normal. Chart I shows this extreme irregularity in a two-hour record. The remissions were very pronounced and the temperature rose to 100° just before death. In other cases the course is singularly like that of typhoid fever and for days the two-hour temperature chart may not show a variation of more than a degree. This is well illustrated in Chart II from Case 17. This patient had the facial aspect of a case of typhoid fever. Chart III from Case 18 shows also a very steady fever with but slight remissions to the time of death on the fifteenth day. Chart IV from Case 15 presents a still more marked resemblance to a typhoid fever curve particularly in the daily remissions, giving the spiked chart with which we are all so familiar in the third week of the disease. Intermittent, exacerbations, and great irregularities similar to those in tuberculous cases are very pronounced in the more chronic cases. Chart V from Case 16 gives the maximum and minimum daily temperature from the twenty-ninth to the twenty-ninth day. It will be noticed how variable is the time of the highest point of daily fever. On 13 days the maximum temperature was in the morning—an inverse type, to which many writers have referred, in this disease. The exacerbations are better shown in a two-hour record. In Chart VI from Case 15 the intermittent type is shown, but the paroxysms are readily distinguished from those of tertian malarial intermittent fever by their prolonged course. In cases of this sort, when chills occur, the picture is very suggestive of malaria and one can understand why some of the older writers regarded the disease as a malarial. The chart of Case 8 is worth a passing comment. After a very steady temperature on the ninth, tenth and eleventh days the record on the twelfth day was normal. On the thirteenth day there was a paroxysm without a chill, lasting from 10 a.m. on June 19th to 4 p.m. on the 21st. On the fourteenth and fifteenth days the temperature was normal. On the evening of 16 p.m. the fever rose and the paroxysm lasted through the sixteenth day, and at 4 p.m. the patient complained of decided chills. On the seventeenth day there was no fever. At 10 a.m. on the eighteenth day the patient had a rigor in which the temperature rose to 104° F., the paroxysm lasted more than 30 hours. Then, on the twentieth, twenty-first, and twenty-second days he had recurring attacks, two with chills, the one on the twenty-second, with out chill, extended into the twenty-third day. After this the patient's temperature remained normal and he recovered rapidly. During these attacks he complained a great deal of pain in the head and back. The spleen was not enlarged. The blood was

II—BACTERIOLOGY OF CEREBRO-SPINAL FEVER

Until within the past few years the etiology of cerebro-spinal fever has been obscure and a majority of observers regarded the organism found in the meningeal exudate as the pneumococcus or a variety of it. More than 12 years ago, however, Weichselbaum described a diplococcus with special cultural peculiarities which he regarded as the specific organism of the epidemic form of the disease. Little or no attention was paid to his communication until 1895, when his observations were confirmed by Jaeger. So little notice, indeed, had they attracted that neither Ormerod in Albutt's "System" (vol. i, published in 1896), nor Latimer in Loomis and Thompson's "System" published in 1897, mention Weichselbaum's organism. The work of Heubner in Germany, and more particularly the studies of Councilman, Mallory, and Wright, have fully confirmed the observations of Weichselbaum, whose organism, known variously as the meningococcus and the diplococcus intracellularis meningitidis, is now regarded as the specific cause of the disease. As the bacteriology of the subject is very fully discussed in the monograph by Councilman and his associates and in the just issued article by Netter in vol. xvi of the "Twentieth Century Practice," I shall confine my remarks to an account of our experience in the study of the cases which have been in my wards during the past year. To Dr Norman B. Gwyn, who has charge of the bacteriological work in my clinical laboratory, and to Dr N. McL. Harris, bacteriologist in the pathological department of my colleague, Professor Welch, I am under special obligations for their careful study of the cases during life and after death. The meningococcus in cover slips made from the exudate has usually a diplococcus form and lies within the polynuclear leucocytes, hence the definition "intracellularis." Many of the cells may be stuffed with them. They may also occur free. It stains with the ordinary staining reagents and is decolourised by the Gram method. It grows best on Löffler's blood serum, on which it forms "round, whitish, shining, viscid looking colonies with smooth, sharply defined outlines which attain a diameter of one to one and a half millimetres in 24 hours" (Councilman). In cultures it is usually short-lived, but Netter states that Germano has found that it resists desiccation and has preserved its vitality to the end even of 90 days. He states also that Neisser has shown that the organism is transportable by atmospheric currents, even the most feeble, and that it is very susceptible to aerial convection. It is found in the cerebro spinal exudate, rarely elsewhere in the body, but it has been isolated from the blood, the pus from the joints, the pneumonic areas in the lungs, and the nasal mucus. The organism is feebly pathogenic for animals. Rabbits and mice resist subcutaneous inoculation. Heubner and Councilman and his associates have produced typical meningitis by inoculating cultures of the meningococcus beneath the spinal membrane of goats. Our clinical and pathological experience with the organism is as follows. In 21 cases which I have seen the lumbar puncture was made in 16. In three patients seen in consultation the diagnosis seemed to be so clear that lumbar puncture was not made. In Cases 1 and 2, both mild, the puncture was made, in one on the seventh day and in the other on the sixth, but no organisms were found. Cases 3 and 4 were admitted late in the disease and it was not thought necessary to perform it. Of the remaining 14 cases, in 13 the diplococcus intracellularis was present on cover slips and in cultures. In the remaining cases its presence was doubtful on the cover slips and the staphylococcus grew in culture. Of the cases which came to necropsy, five in number, the bacteriological results, as given by Dr Harris, are as follows. Necropsy No. 1104, meningitis, meningococcus, the pneumococcus from a pneumonic area in the lung. No. 1189, a case with extensive arthritis, in which the diplococcus intracellularis was found in the blood and joint tissues during life, as well as from the meninges. Post mortem, the meningococcus was separated in pure cultures from the cord and brain, and from the lung the pneumococcus and the bacillus lactis aerogenes, and from the blood in the coronary arteries the pneumococcus. The other organs were sterile. In Case 10 (Necropsy No. 1247), on which laminectomy had been performed the spinal meninges at the time of death (about two months later) were perfectly normal.

At the operation the staphylococcus grew from the culture. In No. 1314, a case in which laminectomy was performed, the meningococcus isolated from the meninges both during life and after death. The bacillus coli communis, the bacillus lactis aerogenes, and the staphylococcus pyogenes albus were also isolated from a broncho-pneumonic area in the lung, the pneumococcus and the staphylococcus pyogenes aureus, in spleen the staphylococcus pyogenes citreus, and in thrombus in the superior longitudinal sinus and in the pelvis of the left kidney the streptococcus septicus faciens (Sternberg). This case had a diptheritic hæmorrhagic cystitis. No. 1364, a very protracted case, in which death occurred in the twelfth week and from the meningococcus had been isolated from the spine twice, from the meninges post mortem the streptococcus pyogenes and the bacillus coli communis were isolated, the staphylococcus pyogenes aureus and the bacillus coli communis from the broncho-pneumonic areas in the lung, a fatal case outside the hospital the meningococcus pneumococcus, and the bacillus coli communis in cultures from the cerebral meninges. There was no pneumonia in the lungs.

[Dr Osler here said that in the first cases the method recommended by Councilman was followed, namely, the use of blood serum "slants." Such was to be almost useless on account of contaminating organisms for out of a series of eight tubes only one gave cultures. In the other cases the exudates and fluid plated out in alkaline 5 per cent glycerin agar, a procedure which gave entire satisfaction. He then considered subject of microbic association in cerebro-spinal fever continued.]

On the whole, then, our observations support the views of Weichselbaum, Jaeger, Heubner, Councilman, and others that in epidemic cerebro-spinal fever there is an organism with special cultural peculiarities which may reasonably be regarded as the exciting cause of the disease. Netter, among recent observers, seems to doubt this and says that he only found the diplococcus intracellularis in 16 out of 21 cases, and in 10 of these the pneumococcus was present at the same time. His most recent statement in the "Twentieth Century Practice" (1899) is worth quoting: "Certain observers, and more particularly Jaeger and Heubner, believe that the diplococcus intracellularis is the sole pathogenic agent in epidemic cerebro spinal meningitis and that the pneumococcus has no influence whatever in the production of this true epidemic meningitis. Councilman is disposed to think that the pneumococcus can, without any doubt, cause meningitis, although he appears disposed to admit that in the majority of cases the pneumococcus has been most surely established the rôle of the diplococcus. Netter's position is most illogical. Throughout the 'Twentieth Century Practice'—in many ways the very best in literature—he assumes that the cause of epidemic cerebro-spinal fever, may be caused either by the pneumococcus or the diplococcus intracellularis. That the diplococcus is universally acknowledged, but it is in the highest degree unlikely that a remarkable specific affection in the cerebro spinal fever should be caused by two different organisms. Towards the close of the article the incorrectness of this view seems to impress him, for he says that the two diseases (i.e., pneumonia and cerebro-spinal fever) are absolutely identical."

III—DIAGNOSIS OF CEREBRO-SPINAL FEVER

Meningitis is not always easy to recognise clinically, with it than with pericarditis are even more common. The unexpected meningitis of pneumonia, of Bright's disease and of other chronic affections teaches us how latent may be the process, on the other hand, who has not in typhoid fever and in pneumonia made a positive diagnosis of meningitis and has found post mortem the cerebro spinal membranes perfectly free? Sooner or later the truth of Stokes's dictum is brought home to each one of us. There is no single nervous symptom which may not and does not occur independently of any appreciable lesion of the brain nerves, or spinal cord. The anatomical classification of lepto-meningitis is not very satisfactory and, as I have stated, there is great lack of uniformity in the terms employed. The nomenclature of the Royal College of Physicians of London recognises four groups—paralytic,

³ Jahrbuch für Kinderheilkunde, 1891 und Deutsche Medizinische Wochenschrift, 1897

in only three was a leucocytosis absent. The lowest count was 6500 per cubic millimetre. Of eight cases with leucocytosis there were four with 20,000 or more white corpuscles per cubic millimetre. The highest count was in a child, aged eight years, 24,333 per cubic millimetre. Altogether the leucocytosis seems not to be so high or so persistent in the tuberculous meningitis.

(d) *Lebilitas*, or more often per arthritis, much more common in cerebro-spinal fever than in other forms, was present in two of our cases. In Case 7 the joint lesion came on with great rapidity and by the fourth day the patient had a multiple suppurative arthritis resembling an acute pyemia. The diplo-coccus intracellulatis was isolated from the pus in the joints. In the other (Case 10) the disease began with arthritis.

2 *Kernig's sign*.—Described by a Russian physician and studied in Germany and France, this interesting sign has not attracted the special attention of English and American physicians, though J B Herriek of Chicago at the last meeting of the Association of American Physicians spoke of its value. It has been present in all of our cases in which it has been looked for. It is, I think, an old observation that the subjects of protracted meningitis, particularly children, very often

CHART IV, CASE 15

CHART V, CASE 16

CHART VI, CASE 15

examined daily for the malarial parasites but none were found. And lastly, Chart VII from Case 15 illustrates the relation of the lumbar puncture to the temperature. After the sixth, seventh, and eighth puncture the fever dropped, after the twelfth it rose.

(c) *Skin rashes*.—Various skin rashes are common in cerebro-spinal fever and form an important feature in the diagnosis. Of 21 cases which I saw during the epidemic, in 13 a skin eruption of some form or another was present. Herpes—of course, the most common—was present in eight cases. A diffuse erythema about the chest and abdomen and

(d) *Blood*.—A careful study of the blood was made in all our cases. A leucocytosis was present in every instance. In four the first blood count was made on the third day and the leucocytosis was 25,900, 14,500, 40,800, and 32,000 per cubic millimetre. The first blood count was made on the fourth day in four cases and the leucocytosis was 26,240, 31,800, 19,300, and 7600 per cubic millimetre. In only four cases did the leucocytes exceed 40,000 per cubic millimetre and the maximum count was on the ninth day in a fatal case 47,000 per cubic millimetre. The leucocytosis persists even in the most protracted cases. In

CHART II, CASE 17

CHART III, CASE 13

over the joints was present in four cases. Petechiae were noticed in eight cases, extensive in only three. In three cases a very remarkable and peculiar rash was present in the neighbourhood of the joints, particularly over the extensor surfaces of the knees and elbows and about the ankles. There was a diffuse, livid erythema of great intensity on which a purpuric herpes developed—a vesicular rash the individual vesicles of which became filled with blood. As the erythema faded and the vesicles dried they could be felt as little nodular hemispherical bodies which persisted for a week or 10 days.

a lad who died in the twelfth week of the disease the leucocytes were 23,000 per cubic millimetre shortly before death. As a rule there was no special reduction in the red blood corpuscles. In one case a moderate anaemia developed and in the fifth week the red corpuscles were only 3,100,000 per cubic millimetre. In one case the diplococcus intracellularis was isolated from the blood during life. Leucocytosis has no special value in the differential diagnosis of the various forms of meningitis. I had an impression that it was not so constant in the tuberculous variety but Dr Parfitt analysed the records of 11 of our cases and found that

medium. The amount of fluid obtained varies from a few drops to 130 cubic centimetres. The samples in these flasks show the large amount which may be removed—one 126 cubic centimetres, another 112 cubic centimetres.

Wentworth claims that within certain limits there is some relation between the degree of turbidity of the fluid and the severity of the symptoms, and this was borne out by our more limited experience. Even in the most protracted cases the turbidity may persist. Only once was a clear fluid removed in an exacerbation. On several occasions a bloody fluid was removed in Case 18. In the wards at the same time was a remarkable instance of septic meningitis in which, after turbid fluid had been withdrawn at one puncture, at a subsequent one, before death, blood flowed from the needle, and post mortem there was extensive meningitis and a rupture of the basilar artery with hæmorrhage. The number of the organisms found bears no constant relation to the intensity of the symptoms. In acute cases they are present, as a rule, in large numbers. The cocci intracellular in the fluid, but we have found them later the disease the less likelihood is there to find the diplococci intracellular in the fluid, and the numbers. The degree of the turbidity of the fluid but the peculiar character of the disease already spoken of was responsible for the remissions. The chart illustrates further the persistence of the leucocytes and the sterile characters of the fluid after the forty-fourth day. I have been for demonstration the lumbar portion of the cord and its membranes. The position of the last puncture can be seen and the repeated operations have caused a slight hæmorrhagic pachymeningitis.

Dr. Osler here discussed the nomenclature of the varieties of meningitis and mentioned that in the United States and Canada the occurrence of sporadic cases of cerebro-spinal fever in the intervals between epidemics had long been recognised. He continued: In Baltimore the figures for the past six years are as follows: 1893, 59 cases, 1894, 26 cases, 1895, 27 cases, 1896, 32 cases, 1897, 22 cases, 1898, 70 cases, during this year the prevalence of the disease was recognised as occurring in a mild form through the city. During the first four months of the present year there has been an increase and the deaths for this period have been 27. *Sporadic cerebro-spinal fever at the Johns Hopkins Hospital*—In the spring of 1898 the first cases of the epidemic form were admitted to hospital and in all 18 cases have been under treatment. Prior to this date only four cases had been admitted which we regarded as sporadic forms of cerebro-spinal fever three within a few days of each other in 1893, and one, a chronic case, in 1892, which has been reported.

It gives the day of the disease, the amount of fluid with drawn, the character of the exudate, the microscopic appearance of the culture results, the leucocytosis, and the effect (1) of the puncture on the temperature. The first puncture, made on the twenty-ninth day of the illness, was negative. From the second puncture 100 cubic centimetres of a yellowish turbid fluid were withdrawn which contained pus.

CASE I.—A man (Hospital No. 7253), aged 57 years, was admitted on May 1st 1893. The patient had been drinking heavily and when admitted was delirious, mumbling and attempting to himself, and picking at the bedclothes, and he resisted actively any attempt to examine him. His friends

TABLE 16.—LUMBAR PUNCTURE CHART

Puncture No.	Day of disease	Amount	Character	Microscopically	Culture	Leucocytes	Temperature

CASE I.—A man (Hospital No. 7253), aged 57 years, was admitted on May 1st 1893. The patient had been drinking heavily and when admitted was delirious, mumbling and attempting to himself, and picking at the bedclothes, and he resisted actively any attempt to examine him. His friends

CHART VII, CASE 15

lis with the thighs flexed upon the abdomen and with the legs in a state of partial contracture, so that they are with difficulty extended. To test for Kernig's sign the patient should be propped up in bed in the sitting position, then on attempting to extend the leg on the thigh there is contraction of the flexors which prevents the full straightening of the leg. On the other hand, in the recumbent posture the leg can be fully extended. Many patients with meningitis are not in a condition to sit up and the test can be equally well made by flexing the thigh on the abdomen, when on attempting to extend the leg if meningitis be present, the limb cannot be fully extended, as shown in Fig 1. Friis found the sign in

FIG 1

Kernig's sign, showing the strong contraction of the flexors on attempting to extend the leg

53 of 60 cases and Netter in 45 of 50 cases. It is stated to be present in all forms of meningitis when the spinal meninges are involved. The presence of the sign is no indication of the intensity of the spinal involvement, as it existed in a very marked degree in a recent case of pneumococcal meningitis in which there was no positive exudate on the spinal meninges, only a turbid fluid. Netter's explanation of the phenomenon is as follows: "In consequence of the inflammation of the meninges the roots of the nerves become irritable and the flexion of the thighs upon the pelvis when the patient is in the sitting posture elongates, and consequently stretches, the lumbar and sacral roots and thus increases their irritability. The attempt to extend the knee is insufficient to provoke a reflex contraction of the flexors while the patient lies on his back with the thighs extended

upon the pelvis, but it does so when he assumes a sitting posture."

3 *Lumbar puncture* — During the past 10 years no single measure of greater value in diagnosis has been introduced than Quincke's lumbar puncture. We are now able in a large number of cases to make a prompt decision as to the existence of meningitis and are further enabled to recognise the form of the disease. I shall not detain you with details of the technique, available now in all text-books, and recently considered at great length in an elaborate "Referat" by Neurath.⁵ It is a simple, quite harmless procedure and in a majority of the cases can be done without general anaesthesia or with the aid of a local freezing mixture. A dry tap is rare in cerebro-spinal fever, the needle may be plugged with fibrin or a nerve root may come directly against the orifice. Puncture in the third or fourth interspace may be negative, while in the second a free flow is secured. In one of our early cases in which no fluid was obtained the necropsy showed an exudate as thick as butter, with little or no fluid. A first puncture in a case is very often negative. Though simple, the technique is, like other procedures of the kind, bettered by practice. Very often at first a few drops of blood flow, then a clear or turbid fluid, either drop by drop or sometimes in quite a strong stream. The fluid may be clear, turbid, purulent, or more rarely a brownish yellow or quite bloody. In a great majority of the cases when meningitis is present the fluid is turbid. In rare instances clear fluid may be obtained when meningitis exists and in a protracted case the fluid may be turbid at one puncture and clear at the next. Several observers have noted that the fluid may become clear in the intermissions of the disease. A clear fluid may be obtained from a puncture in the second lumbar interspace, while lower down a turbid fluid may be withdrawn. I saw this possibility very well illustrated in a

recent necropsy, the fluid in the lower dorsal and upper lumbar regions was perfectly clear while that in the lower lumbar and the sacral regions of the canal was very turbid and contained numerous flocculent masses. The fluid should be allowed to flow into a sterilised test-tube. When the fluid is at all turbid there is usually a slight sediment and a coagulation of fibrin. Cover glass preparations are made either directly from the turbid fluid or, if the turbidity is slight and the cell elements few in number, after it has been centrifuged. Cultures should be prepared at the time of making the lumbar puncture by allowing one or two cubic centimetres of the fluid to flow on to a Löffler blood serum

⁵ Centralblatt für die Grenzgebiete der Medizin und Chirurgie, Band I

Five days before entrance, directly after supper, she vomited and complained of headache, later in the evening she became delirious. Two days after the head was held stiffly and she had much pain in the back of the neck. She had fever, rapid pulse, loss of appetite, and constipation. On admission she was conscious, but very irritable and difficult to examine. The head was arched back and could not be brought forward. The pupils were equal and reacted to light. There was a marked slight internal strabismus. There was nothing of moment found in the examination of the chest and abdomen. She was very tender in the suboccipital region, but there was no sign of disease of the cervical spine. Lumbar puncture on April 1st was negative. For the first week the condition remained about the same, the child could be roused and answered questions, the strabismus persisted, there were no changes in the optic nerves. The temperature ranged from 100° to 104° F. The arching of the head and neck continued, the eyes looked directly upwards (Fig 2). On the 17th a rash appeared—a diffuse erythema over the face, neck, and chest with papules. The rash faded in three days. The temperature ranged from 102° to 104°. On April 19th a profuse purulent discharge appeared from the nose which showed the pneumococcus on cover slips, but in cultures only the staphylococcus aureus grew. She could still be roused, the attitude remained as shown in the illustration. There was no optic neuritis. Throughout the 18th the temperature dropped from 105° to 97° on the morning of the 19th and continued about 97° until her death on the morning of the 21st. One of the most remarkable features was the retention of consciousness to within a week of her death.

FIG 2

Pneumococcal meningitis—cervical opisthotonos

The necropsy (No 1082) showed exudate over the sulci of the hemispheres. The base, from just behind the optic commissure, over the pons and lateral lobes of the cerebellum was covered with a soft yellow exudate. The posterior surface of the spinal cord showed the same. The ventricles were much distended with a turbid fluid. There was suppuration of the mucous membrane of the nose and of the ethmoidal and sphenoidal sinuses. Cultures showed the pneumococcus in the cerebro-spinal exudate and from the nasal pus the pneumococcus and the staphylococcus aureus.

(c) *Primary pneumococcal meningitis*.—Future investigations will decide the proportion of cases of primary cerebro-spinal meningitis due to the pneumococcus and to the diplococcus intracellularis, and it will be an exceedingly interesting study to determine whether there are clinical differences such as separate so decidedly the meningitis complicating pneumonia from the cerebro-spinal fever. Judging from the bacteriological records given by Councilman, Mallory, and Wright, and those of the Pathological Laboratory of the Johns Hopkins Hospital, the primary pneumococcal meningitis is rare in America—certainly much less infrequent than the secondary forms. Two of Councilman's 10 cases, both infants, one aged 10 months, the other

aged six days, were primary. I cannot gather from his statistics how many of his cases were primary, nor will consulting the original can one say how many of the 13 of sporadic meningitis studied by Malenchini (quoted by Netter) belonged to this group. Of our eight cases stated, only two were primary. One of these is quoted.

CASE 6.—A man, aged 44 years (white), was admitted 6.30 P.M. on Sept 1st, 1897, in an unconscious state seen by his brother on Saturday, August 29th, he was quite well. After going to bed on the 30th, he had a severe chill. On Monday he was too ill to go to work, the evening he became delirious and ever since had fever, had been restless, difficult to restrain, and very irritable. On admission the temperature was 105° F and the pulse 136 and small. Dr. McCrue saw him a few minutes after admission. He had been put to bed and took very full and careful of the condition. The face was flushed and he looked distressed. There was no strabismus, the pupils were dilated and active. The head and neck were held stiffly and the arms were held firmly flexed on the chest. There were no signs of pneumonia, the heart sounds were clear. The abdomen was not distended, there were no rose spots and the rectum could not be felt, there was no herpes. The skin showed diffuse mottling, but no purpuric spots were seen. There was no urethral discharge. The leucocytes were 13,500 per cubic millimetre, no alteration in a differential count. The Widal reaction was not present. At 10 P.M. the temperature had reached 106° and he was given a bath at 80° with ice frictions which reduced the rectal temperature to 103°. At 11 P.M. he seemed to be held much more stiffly. At 12 mid

he was much worse and at 12.40 A.M. he died, about three days and three hours from the time of the initial chill. Necropsy (No 989) showed a diffuse purulent meningitis of the hemispheres, the base was much less involved and the ventricles were not at all affected. The spinal cord unfortunately was not examined. There was a recent diffuse nephritis. The urine in the bladder contained albumen and tube casts. There was a general pneumococcus infection, no pneumonic endocarditis, and the pneumococcus separated in pure culture from the meningeal exudate.

V.—NOTE ON THE TREATMENT OF CEREBRO-SPINAL FEVER

In our series of cases we have used special drugs. Morphine has been given to control the pain. Ice sponging has been employed whenever the temperature reached above 102.5° F. Our mortality considering that the cases were as a rule severe, has been low, only eight cases in the hospital and nine among the cases which I have seen. I have alluded to the possible benefits in certain cases of the relief of pressure by the withdrawal of cerebro-spinal fluid. In two

of our cases the spinal canal has been opened, drained, irrigated. Wynter⁹ in tuberculous meningitis removed the spinal process of the second lumbar vertebra and drained the spinal canal. Von Ziemssen first attempted to use therapeutics to the membranes of the cord by injecting a weak solution of iodine in a case of meningitis, and Sahli practised permanent drainage through a cannula catheter. So far as I know, an extensive laminectomy has not been done for acute spinal meningitis until our case on Nov 6th, 1893, in which the operation was suggested and performed by Dr Harvey W. Cushing, the assistant in the surgical clinic of my colleague, Prof. Halstead.¹⁰ The spinal canal was thoroughly irrigated with a salt solution and a quantity of purulent exudate washed out. No change followed in the existing paraplegia. The bladder and kidneys became infected and death occurred about three months after the operation. The paraplegia persisted. Necropsy showed that the spinal meninges were smooth

1. The first step in the process of the investigation is the identification of the problem. This is done by the investigator who is responsible for the investigation. The investigator must identify the problem and the scope of the investigation. The investigator must also identify the objectives of the investigation. The investigator must then develop a plan of action to address the problem. The plan of action should include the methods to be used, the resources to be used, and the timeline for the investigation. The investigator should also identify the personnel who will be involved in the investigation. The investigator should then implement the plan of action and collect the data. The investigator should then analyze the data and draw conclusions. The investigator should then report the findings of the investigation to the appropriate authorities. The investigator should also provide recommendations for the prevention of future problems.

SECRET

NOTES ON THE REVISION OF THE

SECRET

The following is a list of the names of the persons who have been appointed to the various offices of the County of New York, for the year 1890, by the Board of Supervisors, at their meeting held on the 10th day of December, 1889.

Five days before entrance, directly after supper, she vomited and complained of headache, later in the evening she became delirious. Two days after the head was held stiffly and she had much pain in the back of the neck. She had fever, rapid pulse, loss of appetite, and constipation. On admission she was conscious, but very irritable and difficult to examine. The head was arched back and could not be brought forward. The pupils were equal and reacted to light. There was a marked slight internal strabismus. There was nothing of moment found in the examination of the chest and abdomen. She was very tender in the suboccipital region, but there was no sign of disease of the cervical spine. Lumbar puncture on April 1st was negative. For the first week the condition remained about the same, the child could be roused and answered questions, the strabismus persisted, there were no changes in the optic nerves. The temperature ranged from 100° to 104° F. The arching of the head and neck continued, the eyes looked directly upwards (Fig. 2). On the 17th a rash appeared—a diffuse erythema over the face, neck, and chest with papules. The rash faded in three days. The temperature ranged from 102° to 104°. On April 19th a profuse purulent discharge appeared from the nose which showed the pneumococcus on cover slips, but in cultures only the staphylococcus aureus grew. She could still be roused, the attitude remained as shown in the illustration. There was no optic neuritis. Throughout the 18th the temperature dropped from 105° to 97° on the morning of the 19th and continued about 97° until her death on the morning of the 21st. One of the most remarkable features was the retention of consciousness to within a week of her death.

FIG. 2

Pneumococcal meningitis—cervical opisthotonos

The necropsy (No. 1082) showed exudate over the sulci of the hemispheres. The base, from just behind the optic commissure, over the pons and lateral lobes of the cerebellum was covered with a soft yellow exudate. The posterior surface of the spinal cord showed the same. The ventricles were much distended with a turbid fluid. There was suppuration of the mucous membrane of the nose and of the ethmoidal and sphenoidal sinuses. Cultures showed the pneumococcus in the cerebro-spinal exudate and from the nasal pus the pneumococcus and the staphylococcus aureus.

(c) *Primary pneumococcal meningitis*.—Future investigations will decide the proportion of cases of primary cerebro-spinal meningitis due to the pneumococcus and to the diplococcus intracellularis, and it will be an exceedingly interesting study to determine whether there are clinical differences such as separate so decidedly the meningitis complicating pneumonia from the cerebro-spinal fever. Judging from the bacteriological records given by Councilman, Mallory, and Wright, and those of the Pathological Laboratory of the Johns Hopkins Hospital, the primary pneumococcal meningitis is rare in America—certainly much less infrequent than the secondary forms. Two of Councilman's 10 cases, both infants, one aged 10 months, the other

aged six days, were primary. I cannot gather from statistics how many of his cases were primary,² nor consulting the original can one say how many of the 1 of sporadic meningitis studied by Malenchini (quoted by Netter) belonged to this group. Of our eight cases stated, only two were primary. One of these is quoted:

CASE 6.—A man, aged 44 years (white), was admitted 6.30 P.M. on Sept. 1st, 1897, in an unconscious state seen by his brother on Saturday, August 29th, quite well. After going to bed on the 30th, he severe chill. On Monday he was too ill to go to work the evening he became delirious and ever since he fever, had been restless, difficult to restrain, and very On admission the temperature was 105° F. and the pulse 136 and small. Dr. McCrae saw him a few minutes after he had been put to bed and took very full and careful note of the condition. The face was flushed and he looked distressed. There was no strabismus, the pupils were dilated and active. The head and neck were held stiffly and the were held firmly flexed on the chest. There were no signs of pneumonia, the heart sounds were clear. The abdomen was not distended, there were no rose spots and the could not be felt, there was no herpes. The skin diffuse mottling, but no purpuric spots were seen. There was no urethral discharge. The leucocytes were 13,500 per cubic millimetre, no alteration in a differential count of 500. The Widal reaction was not present. At 10 P.M. the temperature had reached 106° and he given a bath at 80° with ice frictions which reduced the rectal temperature to 103°. At 11 P.M. the patient seemed to be held much more stiffly. At 12 M.

he was much worse and at 12.40 A.M. died, about three days and three hours from the time of the initial chill. The necropsy (No. 989) showed a diffuse purulent meningitis of the hemispheres. The base was much less involved and the ventricles were not at all affected. The spinal cord unfortunately was not examined. There was a recent diffuse nephritis. The urine in the bladder contained albumin and tube casts. There was a general pneumococcus infection, no pneumococcus in the endocarditis, and the pneumococcus separated in pure culture from the meningeal exudate.

V.—NOTE ON THE TREATMENT OF CEREBRO-SPINAL FEVER

In our series of cases we have used no special drugs. Morphine has been frequently given to control the pain. Ice sponging has been employed whenever the temperature reached above 102.5° F. Our mortality considering that the cases were as a rule quite severe, has been low—only eight cases in the hospital and nine among the cases which I have seen. I have already spoken of the possible benefits in cases of the relief of pressure by the withdrawal of cerebro-spinal fluid. In two

of our cases the spinal canal has been opened, drained, irrigated. Wynter³ in tuberculous meningitis removed the spinal process of the second lumbar vertebra and drained the spinal canal. Von Ziemssen first attempted to use the therapeutics to the membranes of the cord by injecting a weak solution of iodine in a case of meningitis, and Sahli practised permanent drainage through a cannula catheter. So far as I know, an extensive laminectomy has not been done for acute spinal meningitis until our case on Nov. 6th, 1898, in which the operation was suggested and performed by Dr. Harvey W. Cushing, the assistant in the surgical clinic of my colleague, Professor Halstead.⁴ The spinal canal was thoroughly irrigated with a salt solution and a quantity of purulent exudate washed out. No change followed in the existing paraplegia. The bladder and kidneys became infected and death occurred about 10 months after the operation. The paraplegia persisted. The necropsy showed that the spinal meninges were smooth and

[illegible][illegible]

There was therefore administered on the afternoon of the 17th day after the onset of symptoms and arrangements were made either for the retention of material in the rectum or for defecation. A bar would certainly which might be found. The abdomen was opened into the area, but the abdomen was opened and the rectum was found. On cutting into the peritoneal cavity the escape of a quantity of dark blood at once settled the question of the nature of the case. The hand was however introduced through the opening for the sake of further examination and the section of a small rough body in the right hand of the ovary placed the pathology of the accident beyond a doubt. Another opening was then made below the umbilicus and a tube to the left of the middle line was introduced that more than three pints of blood were present in the peritoneal cavity. Most of this was liquid, but much also coagulated as clot. Some was found in Douglas's pouch, by the greater portion was in the lower cavity of the peritoneum above the pelvis. It was washed out with boiled water and the left broad ligament and the parts attached to it were drawn into view and examined. The uterine and left-organized clot which is shown in the illustration and was found to be attached to the upper and part of the ovary well from the tube. It had evidently been extended through the rent in the ovary and had become attached to the place at the time of rupture. It broke away from its "seat" while the part was being removed. Nearly the whole of the tube and the greater part of the broad ligament were taken away. The right ovary and tube were examined and found to be healthy.

presence of a pelvic tumour, or other indications of gestation make their appearance and tend to bring these cases into line with ruptures of later date. Under these circumstances it may be of some use to draw attention to the main points of distinction between early and later ruptures.

Ruptures which occur before the end of the first month of gestation differ from those of later date in the following particulars, viz. 1 As regards their history all the usual signs of pregnancy may be absent. Menstruation may be regular. Vomiting, breast pigmentation, and other indications of conception have not had time to put in an appearance. 2 Local examination may reveal no evidence of the presence of a tubal or other swelling. There may not be the slightest bulging or boggy of Douglas's pouch to suggest the presence of escaped blood. 3 The initial symptoms may at once divert attention from the pelvis. In all four cases which I have seen the seat of pain has been in the abdomen and not in the pelvis. In two pain was first felt in one iliac region. In the other two it first appeared in the "small" of the back and in one of them about to be described agonising pain was felt almost simultaneously in the region of the splenic flexure of the colon. 4 The later symptoms may also be abdominal and not pelvic. Thus in two of these cases no local indications of hæmatocoele could be detected even while the patients were under the influence of an anæsthetic, and in spite of the fact that in one of them nearly three days elapsed between the rupture and the examination. In the other two the only sign of any importance was the presence of a small tumour in the broad ligament. 5 It might be expected that the rapid onset of extreme anæmia would furnish a valuable clue to the nature of the case. But as a matter of fact no reliance could be placed on this symptom in any of the cases I have seen. It is true that anæmia was present, and severe anæmia, but there was no more pallor or restlessness or disturbance of the pulse than may be noticed in some cases of severe shock from the perforation of gastric ulcers in chlorotic patients. 6 The symptoms may point positively to some other morbid condition. Thus in one of these cases there was every indication of the accident having been due to the rupture of a gastric ulcer, and though it was noticed that there was a large quantity of fluid lying free in the abdominal cavity no help to diagnosis was derived from this fact. Neither Dr Abram (who pointed out this symptom) nor I could suppose that this fluid was blood, for the anæmia did not seem sufficiently severe. It misled me into forming the opinion that the patient might have had a latent ovarian cyst and that her symptoms were possibly due to its twisting and rupture. In Dr Benham's case, also, so much blood was poured out as to cause dulness in the flanks. In the last of my cases the symptoms were so much like those of acute intestinal obstruction that the abdomen was actually opened for the purpose of dealing with that complaint.

From these reasons it is evident that these very early ruptures must sometimes be extremely difficult to diagnose. This difficulty will be appreciated when I say that in the last case which I have described, though both Dr Abram and I were fully alive to the possibility of the rupture of an extra uterine sac having occurred, and though we put many leading questions to the patient and made careful bimanual examinations both before and after anæsthesia, we failed to elicit any indication of pregnancy and were compelled by all the rules of evidence to dismiss from our minds the idea of the case being due to that cause. At the same time it must be noted that, as a rule, there are certain straws of evidence to show in which direction our diagnosing faculties should be directed. Thus, in my first case there had been slight uterine hæmorrhage, which came on after the cessation of the usual "period" and my third case was correctly diagnosed before any severe hæmorrhage had taken place from two indications alone—one being irregular and painful uterine hæmorrhage and the other the presence of a small round tumour beside the left ovary. Moreover, in the fourth case, in which indications of pregnancy seemed to be absent, the patient was able to tell us after she recovered that she had had discomfort in the breasts such as she had before experienced soon after conception. But she was too ill to remember this slight but important symptom before the operation was commenced. As the two cases I am now about to report form a regular series with those I have already published, it seems best to treat them as such. The first of these two will therefore be regarded as the third of the series.

CASE 3.—The patient was a woman, aged 23 years, who

had been married six weeks when I first saw her. Her previous medical history was uneventful except that she had suffered from dysmenorrhœa, which had sometimes been sufficiently severe to confine her to bed for a few hours. Menstruation was "regular." She began to menstruate 14 days after her marriage. This period was unattended by the usual pain and did not cease at the end of four days, as her periods had previously done. From that time the flow continued almost incessantly but varied greatly in quantity and sometimes ceased altogether for a few hours. It was not markedly shreddy and only occasionally contained clots. After a few days she began to experience occasional pains of a cutting nature in the upper part of the right side of the abdomen and was also afflicted with flatulence. She then consulted a medical man in the town where she was living and, according to her own account, was treated for "spasms" and indigestion. After a short time she sought further advice and was treated for "dysmenorrhœa." Meanwhile her symptoms increased so much in severity that sometimes when attacks came on she would cry out with pain or roll about on the bed or on the floor. When I saw her four weeks and two days after the onset of menstruation there were no signs of pregnancy except that on bimanual examination the uterus felt large for a nulliparous woman, though the sound showed a cavity of only two and a half inches in length. The uterus moved freely, but as the fundus was dragged over to the left a sharp pain was produced similar in nature and situation to that of which she had complained before. On the right of the uterus, but distinct from it and easily moved, was a swelling which seemed to consist of two parts, the lower being as large as a small walnut, while the upper was smaller and could not be clearly defined. At the time I thought they were connected, but the abdomen was tender in every part and particularly about the uterus, so that I could not examine it thoroughly. It was afterwards found that the lower of these swellings was the ovary and the upper the enlargement in the tube. The last attack of pain had been so severe that I thought it possible the sac had already ruptured or that the ovum had aborted into the abdominal cavity. This view was indicated also by the great tenderness of the abdomen, which was like that produced by the presence of blood. I therefore gave the patient some opium, and after explaining the nature of the case to the friends decided to watch the course of events. From this time both pain and discharge ceased for 10 days, but I kept the patient in bed, much against her inclination. The opium was not continued after the first three days. After 10 days the pain began to return and while I was making arrangements for an operation she was suddenly overcome with an attack which exceeded in severity any that she had yet had. This came on suddenly and without warning while she was asleep and caused pallor, faintness, and vomiting. Bimanual examination of the uterus revealed no alteration except that the abdomen was again very sensitive, as it had been before the previous attacks. I now got Dr Marriott to see her and he agreed with me that the condition was undoubtedly due to the rupture of a gestation sac and that abdominal section should be undertaken without delay.

On opening the abdomen a quantity of dark blood, to the amount of a pint or more, escaped through the incision. The specimen, of which I give an illustration (Fig 1), was then removed from the right side of the uterus and the abdomen was washed out with boiled water. The left tube and ovary were quite healthy. The condition of the patient for three days after the operation gave rise to anxiety owing to persistent abdominal pain and distension, frequent eructations and vomiting, and obstinate constipation. At the end of that time some sulphate of magnesium which had been given her in small and repeated doses began to act and the subsequent history of her recovery was uneventful.

An examination of the specimen removed showed that the ovary was large and that in the middle of the length of the tube was a circumscribed bulging of the wall measuring 1.8 centimetres in length and 1.2 centimetres in width. The wall of this sac showed no obvious rent in the fresh state, but in three places organised clots had collected where minute ruptures had taken place. One of these small collections of fibrin was not readily seen and was too tough and adherent to be removed, another was capable of being displaced, and the third and largest and most recent, which was situated on the summit of the sac, was still soft and could be easily stripped off. On carefully lifting up its edge

upwards at the time of the final hæmorrhage and finally after its displacement from the Graafian follicle. It was attached so loosely that it broke away inadvertently while it was being handled. It is evident, moreover, that the attachment could not have been of long duration inasmuch as it was attached by a part where the clot was comparatively new. It will be noticed that this mole is of the shape of a "Tyrolean hat," the old decoloured clot forming the body of the hat and the fresher clot the brim. The older and firmer part can be lifted into the cavity of the ovary, and though it is not quite of the same shape it has every appearance of having at one time been in that situation, for the more recent part of the clot projects in a way which is shown in the figure and in so doing exactly seals up the opening. It is evident from the appearance of the mole that hæmorrhage must have taken place on one occasion, but it could not be ascertained that the patient had experienced any previous symptoms such as might have been expected from such a cause. In all probability the first hæmorrhage or hæmorrhages were too slight to cause pain, and it was only the final outburst which gave rise to disturbance. Such a specimen as this is of far more importance in the establishment of the possibility of ovarian pregnancy than if it had been of late conception, for under the latter circumstances, the seat of conception appeared to be in the ovary, the mere size of the egg would bring it into relation with adjacent parts in such a way as to leave room for doubt as to its true nature. This specimen seems to prove not only that the sperm cell of the human being sometimes reaches the ovary but that it is capable of finding its way through solid tissues, such as that of the stroma of the ovary.

NON-FATAL PERFORATION IN A CASE OF TRANSFUSION, HÆMATEMESIS, BY C. J. WHITBY, M.D. CASE OF

I HAVE recently had under my care a case of gastric ulcer presenting some unusual features which I think deserve to be recorded. The patient, who was 37 years of age, arrived at the Clifton Spa on Jan. 13th, 1899, and I was at once sent for and found him bent double with pain in the stomach. He had been treated by me here for a fortnight in July, 1898, for severe dyspepsia associated with pain in the back and had then been told of the probable existence of ulceration. He had gone away somewhat better but had returned to the hydrophobic establishment on Nov. 25th, Dec. 2nd, and Dec. 15th, 1898, on each occasion remaining two or three days only. On the last occasion the symptoms of ulceration were more definite—there had been slight hæmatemesis (fluid blood) which had occurred while the diet was restricted to milk and soda. I then warned the patient that he ought to make up his mind to give up work for a time and submit to a proper course of treatment, but this advice he did not see his way to adopt. On Friday, Jan. 13th, he told me that he had been in agony with pain since Sunday and taking almost nothing. The acute pain had been induced by an indigestion meal of beef and port wine. There had been several attacks of hæmatemesis, each followed by an indigestion Hot fomentations were now administered with some slight relief and as soon as the patient was in bed I gave one third of a grain of morphia sublingually and some hours later one of Burgess's food per rectum. Three suppositories were inserted. This appeared to arrest the assimilation of the nutrient enemata, for two hours later (11 P.M.) I found him suffering from severe gripping pains and evident flatulent distension of the cæcum and to a lesser degree of the colon. To relieve this a hot enemata was administered, which caused an action of the bowels and a free discharge of flatus. The effort of defecation induced a severe quantity of altered blood being ejected. As events turned out it was extremely fortunate that the stomach was emptied in this way. On the following day

rectal feeding was continued and nothing of importance occurred until about 3.30 P.M. At that time, whilst lying peacefully in bed, the patient suddenly felt a sharp pain in the right hypochondrium, followed by abdominal rigidity, marked dyspnoea, and a peculiar sense of flatation of the right lung. The pain was of a scalding character and the patient's first thought was that a hot water bag which rested on the epigastrium had sprung a leak. Shortly afterwards I arrived and found him in a slight rigor, the temperature was normal, the pulse was 120, the extremities were cold, and the expression was haggard and anxious. There was extreme tenderness in the neighbourhood of the pylorus, liver and duodenum was present, but the mucus of the right side of the abdomen were tensely resistant. The temperature gradually rose to a little over 99° F. That evening the patient was seen by Mr. C. Morton and Dr. Mitchell. The former gentleman agreed with me that probably a perforation of slight extent and possibly of a ruptured character had occurred. All three of us after careful consideration agreed that as no change for the worse seemed imminent and as the stomach had been empty for many hours the question of operation might be deferred until morning. The patient passed a quiet night and the condition in the morning was practically unchanged. Tenderness near the pylorus was intense and the percussion almost up to the clavicle. Nutrient enemata were administered two or three times daily, each containing 10 minims of morphia solution and a drachm or more of liquor cretæ. The evening temperature on this and on several succeeding days was from 99° to 99.4° and the morning temperature was subnormal. On the third day (Jan. 17th) the patient first complained of a cough. The desire to cough was almost constant, but the attempt to do so was very painful and it was with great difficulty that the patient expectorated some greenish tenacious sputa. On the next (the fourth) day I detected some rhonchi at the base of the right lung. The right side of the thorax also disappeared very gradually. By the sixth day the symptoms of a localised pneumonia (e.g., pyrexia, pain, tenderness, and increased resistance) in the right hypochondrium) had almost cleared up, but the cough was very troublesome and the expectoration was free and mucopurulent. (Chests) nutrient suppositories were being administered in alternation with enemata of broth and Burgess's food, but on the sixth day aerated milk by the mouth was tried but as it caused some pain it was discontinued. The rectal enemata, however, were so badly depotised milk, two teaspoonfuls being taken at intervals of about 10 minutes. From the tenth to the sixteenth day rectal feeding was resumed because of a return of pain, but the enemata were badly retained and nutrition was obviously failing. Then depotised chicken jelly was tried in teaspoonful doses and being well borne, custard puddings, &c., were gradually added and the patient began to pick up strength and to recover appetite. The cough by this time had disappeared as had also the gastric pain and tenderness. The weight on Jan. 31st was only 6st 8½lb but on Feb. 11th it had increased by 3½lb and the patient now seemed well on the road towards recovery. Two days later (Feb. 13th) there was a sudden return of pain, vomiting of a clear fluid jelly. The patient had been taking calomel jelly for some days and, I think, more freely than usual. The appetite, which had been extremely good, now failed entirely. Rectal feeding was resumed, the pain diminished but not the nausea which was so constant and distressing that on the following day I washed out the stomach, thus removing a large quantity of jelly. Rectal feeding still having the small and colour of calf's foot jelly. Rectal feeding, always ill borne, was so obviously failing to keep up the nutrition that I felt it advisable to resume oral feeding at all hazards. At this period there were frequent attacks of syncope, so that the patient was unable to sit up in bed or to eat without assistance, and all appetite had failed. Nausea was constant and emaciation was extreme. There was at about this time a slight improvement in the blood rejected having the usual coffee-ground appearance. The food given by the mouth was of the

uterus did not appear to be enlarged. The patient gradually rallied from the operation and slowly recovered. No deciduum was passed.

This case is of great interest for two reasons. It is, in the first place, an instance of the rupture of a gestation sac which could hardly be a month old. It is, therefore, one of those cases, referred to in the first part of this article, in which diagnosis is rendered difficult if not impossible from the absence of indications of pregnancy and of pelvic symptoms. But its chief claim to notice arises from the

me to be no question but that the specimen, which is represented in the illustration, is a product of conception, for the chorionic villi are obvious and unmistakable. I was, however, glad to have his opinion on the seat of the lesion, for his letter implied that it was without doubt ovarian. To have further confirmation on this point I sent the specimen to Mr Targett, and as the result of his examination fully agreed with me that the case was one of ectopic gestation and that there was good reason for the belief that impregnation had occurred within the substance of the ovary.

In the fresh state the Fallopian tube was smooth and without a vestige of scar, while the fimbriae when floated out in water were all separate from one another and from the ovary and other parts. The tube was split up for its entire length in order to find if there were any signs of inflammatory or other obstruction or any scar such as might have been produced by the escape of products of conception, but no evidence of any such traces of inflammation or of primary tubal pregnancy could be discovered. There was not a sign of any contraction of the tube or adhesion of the villi. The ovary and tube of the opposite side were pulled out and examined at the time of the operation and found to be perfectly normal. The removed ovary is 3.8 centimetres long and 3.3 centimetres broad. The rent in its substance is 2.2 centimetres long. The interior of the cavity is smooth, its edges are bevelled off gradually and meet together without showing any loss of substance (Fig 2 B and C). The mole which is shown below it was 2.8 centimetres long

fact that it appears to be an undoubted instance of true ovarian gestation. Until lately there was no question but that pregnancy sometimes takes place in the Graafian follicle or in the free cavity of the abdomen. Spiegelberg,⁴ for example, states that he has found details of 13 reliable cases of ovarian pregnancy. But later writers are inclined to doubt the possibility of the occurrence of this variety of ectopic gestation. The opinion of Mr Lawson Tait on this subject is too well known to need comment, and Mr Bland Sutton has given it his emphatic endorsement.⁵ Under these circumstances I thought it best to send the specimen to one of those gynaecologists who are well known to be sceptical of its occurrence. He very kindly wrote to me in reply that the specimen was not one of ectopic gestation at all, that I should find no chorionic villi, and that though it would be as well to have it "microscopied" it would prove to be nothing but a specimen of the rupture of an unusually large Graafian follicle. But there seemed to

and 2.2 centimetres broad, and consisted for the most part of an organised clot, half of which was of recent formation while the other half was of much older date. Projecting from it is a cluster of villi which both to the naked eye and under the microscope are obviously chorionic. The mole was attached at the time of the operation by its posterior surface to the scar situated above and on the inner side of the ovary. Half of this scar is seen at the point F (Fig 2 A), the other half was left behind in the pedicle. It will be noticed that the specimen shows a tear at the junction of the ovary with the broad ligament on the inner side and that just below this rent is the rough surface made by the attachment of the mole. Now, I cannot say how this rent took place for I do not think that I used sufficient violence to produce it at the time of the operation. But it cannot be accounted for in any other way for when the specimen was removed it was so recent and its edges fitted so exactly together that it seemed to be evidently due to a recent tear. The position of the mole above the ovary could be accounted for by the direction of the flow of blood, for it might easily have been washed

⁴ Text-book of Midwifery, New Sydenham Society's Translations, p. 423.

⁵ Mr Bland Sutton says that he is 'convinced that ovarian gestation has no existence.' (Surgical Diseases of the Ovaries and Fallopian Tubes p. 332.) And elsewhere he has written still more decidedly

1 The temperature was mostly subnormal, and never exceeded 99°. The excessive collapse without signs of disease to account for it, all appeared very ill and were despondent about themselves from the first. The dyspnoea coming on as the vomiting lessened, and the somewhat sudden final termination. That the cases were "atypical" cases of malaria seems negatived by the fact that the place in which the patients were living was not a very malarious one and the type of fever occurring there was a very mild one, also by the absence of any fever and in all except the first of any enlargement of the spleen, and also in the only one in which an examination of the blood could be made by the absence from the blood of malarial organisms and pigment. The absence of clinical and post mortem signs of malarial dysentery was an unsatisfactory explanation. Many of the symptoms point to poisonous poisoning, though the somewhat long course and the absence of diarrhoea seem against this theory. The only article of food suspected was cow's beef which two of the patients had eaten just before the illness as had one other possibly, and which is a substance from its gaseous composition offering a particularly suitable nidus for bacterial growth. It was unfortunate that clinical and bacteriological examinations of the stomach contents could not be made.

Chert. Punjab India.

A CASE OF PENTASTOMA CONSTRICTUM

BY ALBERT J CHALMERS, M D VICE, F R C S ENG
ASSISTANT COLONIAL SURGEON THE GOLD COAST COLONY

By the kind permission of the Right Honourable the Secretary of State for the Colonies I am permitted to publish an account of this case of pentastoma constrictum. Early in 1898 a negro, by name A. Mendi from Sierra Leone, applied for medical relief at the Colonial Hospital at Accra on the Gold Coast of West Africa. He was admitted into the hospital and in the course of a few days he died. At the necropsy large numbers of the pentastoma constrictum were found in the lungs, liver, alimentary canal and peritoneal cavity. As there are not many descriptions of this parasite and of the disease which it causes I consider that a brief account may be useful to anyone interested in tropical diseases.

Pentastoma constrictum was first discovered in 1847 by Pruner in Egypt in the livers of two negroes upon whom he made post-mortem examinations. He apparently did not recognize the zoological position of the parasite, but sent specimens to Bilharz and Von Siebold, who published an account of it, and gave it the name of "Pentastoma constrictum" in their Text-book of Zoology. The next recorded case of Dr Kossany. This observer records the clinical history of the illness and death together with the post-mortem appearances of a negro private of the West Indian Regiment who died in January, 1866, at Jamaica, but who had come from St Helena only eight months previously. After this there is apparently a long interval without any further records till Girard, published an account of the illness and death from pulmonary meningitis of a Senegalese thralldent sent to him by Dr Alphonse and Dr Clouard. These gentlemen had found in the liver of the thralldent characteristic cysts containing the parasite. The patient died at St Louis on the West Coast of Africa, having just arrived from Kayes a town in the French Soudan or Hinterland behind the French Guinea. Such is the history of the parasite as far as I can find it. Numerous references are made in many text books but the above are, I fancy, the only original observations.

With regard to my own case, that of the Mendi above mentioned, the clinical history was as follows. On admission into the hospital the patient was much emaciated and very weak. He had a markedly enlarged and protuberant abdomen. The temperature was slightly above normal and

Zeitschrift für Vergleichende Zoologie Band IV. p. 65.

"Comptes Rendus de la Société de Biologie," 1886, vol. X. series III. pp. 493-471.

He suffered from a hacking cough with expectoration of a little mucus. He apparently suffered from pain in the abdomen and the lower part of the chest, but it was extremely difficult to be certain of his sensations as no one understood his language. The physical signs which were present in the respiratory organs were those of congestion of the lungs with impaired resonance on both sides and much expectoration in which no parasites were to be seen. There was pain on pressure over the abdomen. The bowels acted regularly but unfortunately the faeces were not examined. The liver was enlarged but not tender. The spleen was very much increased in size. The heart was normal but the patient was anemic. When the blood was examined no parasites were to be seen or anything worthy of note. The urinary system was normal, as was the cutaneous system. The patient remained in much the same condition for a few days, but suddenly the temperature rose to 104° F and he became rapidly worse and died. He was mainly treated for congestion of the lungs and it was this disease which was the cause of his death.

The post-mortem examination was made about 17 hours after death. The body was much emaciated and the abdomen was protuberant. On opening the abdomen large numbers of parasites (pentastoma constrictum) were observed moving freely in the abdominal cavity over the surfaces of the various organs, to which some were also attached. The liver contained in its sub-sinuous and projecting on to its surface a large number of cysts each containing a clear fluid in which lay a single parasite coiled up. Some of these were liberated and found to be alive, and were exactly the same as the pentastomata found free in the peritoneal cavity. No parasites were found in the gall bladder or in the bile duct. The substance of the liver was congested and the organ was enlarged. The stomach and intestines were not congested, though they were matted together by old peritoneal adhesions. Attached to the surface of the intestines at a few spots parasites were seen firmly fixed by their hooks. On opening the stomach no parasites were seen, but in the small intestine, except the duodenum, there were large numbers of pentastomata. None were seen in the large intestine. At places in the small intestine there were signs as though the parasites were in the act of passing from the lumen of the bowel through the wall of the intestine into the peritoneal cavity. The spleen was markedly enlarged and congested but contained free from parasites. The kidneys and pancreas were normal. Several parasites were found attached to the peritoneal surface of the bladder, but none were found in the interior or in the wall. The peritoneum everywhere showed signs of old peritonitis, but this was most marked in the region of the liver and the spleen. The diaphragm, except for peritoneal adhesions, was normal, and no parasites were noticed attached to it. In the chest the heart was normal, but the pericardium was much thickened. The lungs were bound down by many old fibrous adhesions and the lungs were markedly congested and cedematous and the bronchi were inflamed. Both projecting on the surface and imbedded in the substance of both lungs there were numerous cysts like those found in the liver and in each of these a parasite was found. No parasites were found in the muscle or among the adipose tissue of the body. The brain and the spinal cord were not examined.

I do not intend to describe the anatomy of pentastoma constrictum in this paper but hope to do so shortly. Nothing as known at present as to the life history of this parasite or as to the means by which it enters the human body. It appears to me that it enters by some means into the alimentary canal and that from this it proceeds to the liver, the cysts in which appear to be dilated biliary ducts, and in the peritoneum. It also seems as though the lungs were affected through the trachea, as the cysts therein appear like dilated bronchioles. The presence of the parasite in the human body sets up inflammation of the lungs and makes out the above mentioned Mendi had been ill a long time before causing the death of the patient, for as far as I could canal or the liver. The disease appears to last some time and the temperature was slightly above normal and

There is no described treatment of this disease. It appears emanation in negroes.

The only possible means of diagnosis would be the presence of the parasite in the faeces in cases of wasting and to be confined to negroes and the described cases came from

lightest description, and though taken with reluctance caused no pain whatever. On Feb 21st at 10 P.M. the patient suddenly woke and vomited an immense quantity of liquid blood. The attendant, who had left him sleeping, found him on his return apparently at the point of death. Blood covered his face and the bedclothing, and there was a large pool of blood on the carpet. On my arrival he was almost pulseless, barely conscious, and deathly white. I administered a large enema of very hot water and sent for Dr. Mitchell Clarke. He advised transfusion which with the aid of Mr. Morton was at once begun but by means of which we hoped at the utmost to be able to keep the patient alive until morning when his friends would arrive. Both median basilics were opened, and altogether something more than four pints of saline solution were introduced into the veins. The immediate effects were extremely disappointing, the volume of the pulse being but little improved, and death appearing to be imminent and inevitable. However, after 4 A.M. when Mr. Morton left, the patient dozed for an hour and awoke somewhat better. I remained with him all day, administering at intervals of about two hours small enemata of brandy and milk, and giving hypodermic injections of strychnine every six hours. He expectorated blood and mucus and passed some blood by the rectum. The patient had been reduced to extreme emaciation and anæmia before the occurrence of this great hæmorrhage and his bloodless and deathlike appearance at this time it is impossible to exaggerate. At nightfall there was a further change for the worse. Respiration became labouring, the pulse was barely perceptible, consciousness failed, and there was rectal incontinence, the faces having a characteristically offensive cadaverous odour. The patient was delirious at intervals and was stone deaf. For 24 hours he continued in this apparently moribund condition, the jaw dropped, there was Cheyne Stokes respiration, and all hope of recovery seemed out of the question. But at about 7 P.M. of the 23rd there was a sudden change for the better. Hearing and, in some degree, consciousness returned. The terrible factor of the rectal ejecta and the prolapsed condition of the bowel still precluded any attempt at rectal feeding, but the patient sipped a little champagne and later some aerated milk. He passed a good night and on the following day took small quantities of peptonised milk at intervals of from 20 to 30 minutes. From this time forward his recovery proceeded without a hitch. For 10 days he was fed exclusively on peptonised milk, then light farinaceous foods, fish, fowl, and at length beef and mutton were gradually added, always without ill effect. The patient gained weight at the rate of from five to six pounds per week and when he left on May 15th he weighed 8 st without his clothes, which (for he is very small and lightly built) is practically his normal weight.

The most interesting point in connexion with this case is the question of the occurrence or non occurrence of perforation. The reasons which lead me to the conclusion that perforation took place are (1) the severity of the symptoms preceding the incident, (2) the suddenness of the localisation and its characteristic nature, (3) the very definite localisation of the pain and tenderness in the neighbourhood of the pylorus and its gradual subsidence during the week following its appearance, (4) the occurrence of a localised peritonitis in the neighbourhood of the lesion, and (5) the extension of inflammatory symptoms to the base of the right lung. The fact of spontaneous recovery is doubtless to be explained as due to the stomach having been empty at the time when the accident took place. As regards the hæmatemesis which occurred on Feb 21st, large as was the quantity of blood which the patient vomited it did not represent the full amount of the hæmorrhage, for the stomach appeared at the time of the consultation with Dr. Mitchell Clarke to be full of blood and a good deal of blood was subsequently passed by the rectum. It may be said that the hæmorrhage would not have happened if rectal feeding had been exclusively employed, but the difficulty was that rectal feeding was so ill borne that there was obvious danger of the patient's sinking from exhaustion. There can be no doubt, I think, that the transfusion saved this patient's life, as the rally on the following day was very marked, though it was followed by a second collapse in which the patient showed all the signs of impending death. I think no one who had seen him as he appeared on Feb 23rd would have hesitated for a moment to say that death within a very few hours was absolutely inevitable.

Clifton, Dr.

OBSCURE CASES OF PTOMAINE POISONING

By A. R. ALDRIDGE, M.B., O.M. EDIN., D.P.H.
MAJOR R.A.M.C.

I AM induced to ask you to publish short notes of these four cases in the hope that some readers may be able to offer suggestions as to their nature and cause. The cases occurred in Englishmen living under practically identical conditions during the hot months in a Punjab station at intervals of a few weeks and their similarity points to a similar nature and common cause.

CASE 1.—The patient was a man, aged 30 years, a heavy drinker, who had been seven years in India and had suffered from malarial fever but not latterly. On admission to hospital on March 19th he complained vaguely of feeling very ill but his symptoms were difficult to localise, pain in the loins and soreness of the throat being the chief. The liver and spleen showed some enlargement, the fauces were rather congested, and the temperature was 98° F. The urine contained neither sugar nor albumin and nothing abnormal could be found in the other organs. On the night of the 20th pain commenced in the epigastrium and there was vomiting of bile stained matter, this continued during the next day, the vomit containing a little altered blood, but at no time was the vomiting very urgent. On the evening of the 21st he became collapsed with severe pain and tympanitic distension of the epigastrium and dyspnoea, and he died during the night. His temperature during the whole illness remained subnormal from 98° to 98° and his bowels were constipated. Post mortem a considerable amount of fat was found around the heart and the left side appeared to be hypertrophied. The liver was cirrhotic and adherent to the under surface of the diaphragm. The transverse colon was enormously distended with gas and the stomach was moderately so and contained food mixed with "coffee ground" matter and showed several congested patches and submucous hæmorrhages along the greater curvature. There was no obstruction at any part of the intestine. A dog fed on the stomach contents mixed with milk suffered no ill effects.

CASE 2.—The patient was a man, aged 27 years. His previous health had been very good. He had never had malarial fever. The illness commenced on May 1st with vomiting of bile stained, and after a few days slightly blood stained, matter. Under treatment this had stopped by May 6th, but he remained very prostrate with a sense of oppression in the chest and dyspnoea. His temperature ranged from 98 to 99° F. Nothing could be learned by physical examination and the urine was normal. The dyspnoea and collapse increased and he died on the seventh day. No post mortem examination was made.

CASE 3.—The patient was a man, aged 21 years. His previous health had been good. The early symptoms were practically identical with those of the former case. The vomit examination gave similarly negative results. The vomit was never very urgent, but the amount of collapse was of all proportion to it. His temperature ranged between 97° and 98° F., and his bowels were constipated. Dyspnoea came on and he died on June 19th, the seventh day of illness. Post mortem adhesions of the right pleura were found and there was a large "white" clot in the right side of the heart. On the mucous membrane of the stomach were a number of hæmorrhagic spots, especially on the posterior surface. The spleen was small and firm, weighed 5½ ounces. Blood from the spleen was examined for malarial organisms and pigment, but none were found.

CASE 4.—This case was almost a repetition of the former ones. The illness commenced on July 6th. The temperature ranged from 97° 6' to 99° F. The bowels were constipated. There were considerable epigastric pain and cramps of the muscles of the extremities. The vomiting as in the former cases, lessened but he did not rally, dyspnoea with livid face commenced and he died on the fifth day. Post mortem congested patches were found on the mucous membrane of the lesser curvature of the stomach and large patches in the small intestine from the duodenum to the ileocecal valve. A large "white" clot was found in the auricle and ventricle.

Several points common to

the island of St Helena the city of Kayes on the River Senegal in the French Sudan of West Africa, and this Mendi came from the English colony of Sierra Leone. Pruner does not state where the two negroes who died in Egypt came from.

In conclusion I wish to thank Mr Henderson, the chief medical officer of the Gold Coast Colony, for his kindness in allowing me to record this case.

Cape Coast

A CASE OF BILHARZIA OF THE VAGINA

By FRANK COLE MADDEN, M.D., B.S. MED.,
F.R.C.S. ENG.,

PROFESSOR OF SURGERY, FULTON GOVERNMENT MEDICAL SCHOOL,
SENIOR SURGEON, KAUFMAN HOSPITAL, CALIF.

IN spite of the extraordinary prevalence of bilharzia along the course of the urinary tract, and to a less extent in the rectum, among the lower classes of the native population in Egypt, it is rare to find a case in which the primary infection is in the vagina. Further, notwithstanding its very susceptible surroundings very few instances of secondary vaginal infection by extension have been noted. Various explanations have been offered to account for the comparative infrequency of severe bilharzia in the female sex, the most reasonable, perhaps, ascribing it to the different habits of life in the two sexes "and in no way do they differ more than in the frequency and manner in which they bathe. River bathing is but seldom indulged in by women, but in countries in which bilharzia is prevalent the men spend a no inconsiderable portion of their day in the water" (Guillouard). This statement, however, does not apply in its entirety to Egypt where bathing is not at all popular. At the same time the 'fellah'—agricultural labourer and the like—does a great deal of paddling in water and moist earth during the day's work. If the theory of infection through the skin is to be accepted this possible water borne inoculation must be considered. It is certain, on the other hand, that many cases of cystitis in the female and (to a less degree) of vesico-vaginal fistulae are due to bilharzia, which does not appear to take on the same papillomatous growth so characteristic of the disease in the genito-urinary tract of the male sex.

The present case was that of a young Egyptian woman who was sent to me by Dr Aly Helder with a view to operation for a tumour of the vagina. She was quite well until about a year ago when she noticed a small pendulous tag in the vagina. She had a little pain over the pubes for a few days at this time. The tag gradually increased in size, fresh pieces appeared and rapidly grew until the vagina was almost completely blocked. There had never been any trouble with the urine but a large piece in the front of the vagina sometimes caused pain during micturition. There were never any rectal, uterine, or bladder symptoms. She had been married for four years and had never been pregnant. Menstruation had always been regular and was not painful. On examination the mucous membrane of the vagina was much prolapsed all round owing to an extreme laxity of the vaginal walls. A considerable mass of much hypertrophied mucous membrane could be extruded and the cervix uteri, quite smooth and healthy, could be felt deep down in the midst of this redundant mass of irregularly papillomatous tissue. The uterus was small and freely movable. The opening of the urethra was hidden by a soft warty mass, but the urethra itself was quite normal. Further examination under an anæsthetic showed that the entire mucous membrane was greatly thickened and hypertrophied owing to a general papillomatous change and almost filled a more than usually capacious vagina. There was a large pedunculated tuft on the anterior wall just behind the orifice of the urethra, and in the rest of the extent of the mucous membrane there were innumerable flat-topped elevations of various sizes intersected in all directions by depressions the depths of which represented the surface of the true mucous membrane. Here and there a more definitely papillomatous formation was present. Looking on the case as a general papillomatous change (1 cause) in the vaginal mucous membrane the greater part of the obstructing anterior mass was removed, a catheter being placed in the bladder to prevent

injury to the urethra or bladder during the operation. The edges of the wound were then accurately sutured with the silkworm gut, and when the operation was complete the outlet of the vagina was very much clearer than before.

The specimen which was examined microscopically by Dr Symmers presented all the appearances of a bilharzia papilloma and numerous ova were found in the submucous tissue throughout the sections. After this unexpected diagnosis the bladder was carefully examined with the sound—the cystoscope has not yet reached Egypt—but beyond a slight roughness posteriorly nothing abnormal was made out. The urine was microscopically examined on several occasions but no bilharzia ova were discovered. The urethra was quite healthy and the rectum was normal. The condition was, therefore, not due to extension from neighbouring viscera and it was thought possible that it was a case of infection from the husband. His statements, however, did not support this idea. He was a soldier, apparently in perfect health, and had never had any symptoms of bilharzia of the urinary tract or of the rectum. He passed a small stone by the urethra when he was nine years of age. All stones in Egypt are suspicious of bilharzia but other symptoms would certainly have appeared had it been due to this cause in this instance. Further, he stated that at the time of his marriage he noticed that his wife had a small tag in the posterior part of the vagina and this had gradually increased in size. A year or more ago he first noticed the tuft on the anterior wall. Thus, though there are slight discrepancies in the two histories the possibility of infection from the husband can hardly be allowed.

It would appear that this is a case of primary infection of the vagina, the pathology of which is practically identical with that so frequently described in the bladder. Thus Leuckart writes: "One may find on the mucous membrane of the bladder single or sometimes grouped excrescences not unlike condylomata with or without pedicles, which may present manifold variations of shape and may be as large as a bean. On section the mucous membrane is thickened and the submucous connective tissue hypertrophied. Both are pervaded by a rich network of capillaries, the vessels being sometimes much dilated and here and there changed to rather large cavities which often contain full grown specimens of the distoma. In the parenchyma of the excrescences, which is formed chiefly of the submucous tissue, numerous eggs are found." A few weeks before the case described above was admitted to the hospital my colleague, Mr Frank Milton, removed a piece of a somewhat colloid papillomatous mass from the anterior wall of the vagina close to the cervix uteri, which presented in less degree many of the appearances above detailed. Unfortunately, no microscopical examination was made. The available literature on the subject here is of rather ancient date, but the case is worthy of record as an unusual form of bilharzia infection, the strict localization of which to the vagina is rather difficult to understand with so many more usual centres of primary infection in such close proximity.

Cairo

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF PROCIDENT UTERUS TREATED BY QUININE INJECTION

By J. ALKMAN, M.D. GLASGOW

A SHORT, thick set woman, aged 61 years, crippled by chronic deforming rheumatism of the knees and feet, had for many years suffered from prolapse of the uterus. She had borne two children and the perineum was deeply rent at the birth of the second child—now an adult. Her husband was a sea-faring man and for many years had been in an asylum. The bringing up of the children had been accomplished by laborious work as a charwoman on the part of the mother. Seven years since complete procidentia took

place and the uterus and bladder remained between the strait of walking with crippled joints somewhat interfered support. Comparative comfort was thus attained, but the then replaced and kept in fair position by a mechanical ligature for a week before advice was sought. They were

On May 29th, 1898 quinine solution was injected into the

with the usual result. About Christmas time the uterus protruded slightly and on Jan. 15th, 1899, a supplementary injection of quinine was given in the broad ligament. Since that date the comfort has been perfect. The patient wears a watch-spring rubber ring to support the cystocele, but the uterus remains firmly fixed with its axis in that of the inlet of the pelvis. The peritoneal structures are absolutely lax but the uterus hangs upon its new supporting bosses which can be readily felt high up in the pelvis. As the patient walks she puts and groans till her face becomes cyanotic, but even this state does not displace the uterus. The patient was last seen on June 8th, 1899.

Considering that the patient is badly fed, that she has little comfort in her home, and that she earns her scanty subsistence by attending to, and often lifting, her three grand children the result is immensely satisfactory.

MULTIPLE NEURITIS THROUGH NEOROSIS OF DENTURE, EARLY REMOVAL OF SEQUEL TRUM, RAPID RECOVERY BY MONTAGUE D. MACKENZIE, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a female, aged 25 years, had suffered from facial neuralgia on and off for years past. In 1894 several decayed teeth were removed and she wore a denture which was ill fitting. Subsequently a few more teeth decayed which were extracted and she wore another denture equally bad. She could not be persuaded to leave off wearing the denture and thus made herself a martyr to pain, resulting in morbid, mental irritability, anorexia, and loss of body-weight. From 11th to 6th in October, 1898. She consulted me on Oct. 10th last for motor paralysis, hyperæsthesia, wasting of the left upper limb, and swelling of the right side of the lower jaw from the external oblique ridge to the symphysis. She had four fairly good lower incisors, but the two canines were much decayed by the classes of the denture and there were four decayed molars in the upper jaw. She was compelled to give up the denture. From Oct. 12th to Nov. 5th she received five sittings of combined electric current cod Heriot and hypodermic emulsion, and phosphobolin. She was put on liquid diet with digestives and hæmoglobin. She also received anæsthetics in succession, and phosphobolin. She gradually disappeared, and by the middle of November she regained motion and the muscular "ratchet" showed signs of filling in. She was also relieved of neuralgic symptoms from other parts of the body. Simultaneously with this constitutional treatment an incision was made along the right alveolar border of the lower jaw, reaching to the osseous surface, encase being used as an anæsthetic, and some purulent discharge was evacuated. The cavity was daily syringed with carbolic acid standing the swelling rapidly increased and caused intense pain. Four leeches were applied externally, giving temporarily relief. Shortly afterwards the sequestrum could be felt by a probe loose in its cavity. On Dec. 1st three grains of encase in solution were injected along the alveolus and the discharging cavity was enlarged. The sequestrum was drawn up by the forceps and was removed from the cavity by the patient with her fingers. Still the

"ON THE EFFECTS OF PRIMULA OBSCURICA ON THE SKIN"

BY E. A. BARTON, L.R.C.P. LOND., M.R.C.S. ENG.

I observe that the subject of the irritation caused by handling the primula obscurica is again drawing some attention and I venture to think that a case of this nature which came under my care a year or so ago may be of interest. A gardener came to see me complaining of irritation and swelling of his eyelids which were so great that he could hardly see. His penis, he said, was painful and swollen and there was a troublesome rash on his hands. Three months previously he had had a similar attack, though not so severe, and on questioning him closely he admitted that at that time he had much to do with primula, of which he had a large number in pots. Nearly a week before the present attack came on the patient had moved all the primula from one hot-house to another, and among them were many specimens of primula obscurica. In the present attack the eyelids and penis swelled before the eruption on the hands appeared, though this followed a few hours afterwards. The irritation and itching were almost intolerable. He had a habit of rubbing his eyes when at work. On examination the lids were very cedematous, especially the lower ones, and were shining and tense. The penis was enormously swollen with cedema, especially round the glans and foreskin. The hands showed an interesting condition. They were hard and horny from manual work but the forefingers and thumbs more especially on the dorsal aspect were cedematous, red, and violently inflamed, the eruption extending over the middle half of the back of the hand and fading away toward the base of the little finger. The eruption consisted of discrete papules and small vesicles scattered pretty thickly on a very inflamed red area which covered nearly all the dorsum of the hand, fading at its edge into healthy skin at the wrist and inner edge of the hand. On the eyelids and periauricular regions were much fewer and more scattered. The patient was not much surprised when I told him the cause of his trouble as he was aware that some of the primula were "poisonous."

In ten days he was practically well and in the meantime he brought me some leaves and flowers to examine. I removed some of the hairs from the leaves and examined them microscopically in glycerine. I found that most of them ended in a fine horny point between which and the main trunk of the hair were some transverse markings or, as I imagined, planes of fission, and I think it not unlikely that the eruption is caused by the penetration of this fine point into the skin where fracture takes place, the point being left in the dermis. This would account for some of the irritation, but it is open to question whether the inflammation is more violent than could be accounted for by simple irritation from where there might be some irritative ferment contained in the hair ends. Another curious fact and I think one worth noting is that occasionally the leaves is a long period between the contact of the leaves and the eruption. Dr. Kirk on one occasion when experimenting in the above case there was, so to speak, an incubation of a week.

Chemical-gardens, W. I observe that the subject of the irritation caused by handling the primula obscurica is again drawing some attention and I venture to think that a case of this nature which came under my care a year or so ago may be of interest. A gardener came to see me complaining of irritation and swelling of his eyelids which were so great that he could hardly see. His penis, he said, was painful and swollen and there was a troublesome rash on his hands. Three months previously he had had a similar attack, though not so severe, and on questioning him closely he admitted that at that time he had much to do with primula, of which he had a large number in pots. Nearly a week before the present attack came on the patient had moved all the primula from one hot-house to another, and among them were many specimens of primula obscurica. In the present attack the eyelids and penis swelled before the eruption on the hands appeared, though this followed a few hours afterwards. The irritation and itching were almost intolerable. He had a habit of rubbing his eyes when at work. On examination the lids were very cedematous, especially the lower ones, and were shining and tense. The penis was enormously swollen with cedema, especially round the glans and foreskin. The hands showed an interesting condition. They were hard and horny from manual work but the forefingers and thumbs more especially on the dorsal aspect were cedematous, red, and violently inflamed, the eruption extending over the middle half of the back of the hand and fading away toward the base of the little finger. The eruption consisted of discrete papules and small vesicles scattered pretty thickly on a very inflamed red area which covered nearly all the dorsum of the hand, fading at its edge into healthy skin at the wrist and inner edge of the hand. TWO CASES OF ERYSIPELAS TREATED WITH ANTI STREPTOCOCCIC SERUM

(Under the care of Dr W MURRELL.)

IN many suppurative conditions the anti streptococcic serum is of value. The serum is chiefly deserving of injection in cases in which septic absorption has occurred, and in which the presence of the streptococcus has been demonstrated. At various times much doubt has been felt as to the connexion of erysipelas with the ordinary streptococcus, but the fact that the anti streptococcic serum has proved useful in cases of erysipelas is a powerful argument in favour of erysipelas being due to the ordinary streptococcus. The anti streptococcic serum is hardly advisable in every case of erysipelas, for the majority of cases have only a short course and early and complete recovery is almost invariable. The serum is likely to prove of most benefit in severe cases of erysipelas of the face, in which the prognosis is far graver than in ordinary cases. The success of the treatment in Case 1 is especially striking. For the notes of the cases we are indebted to Mr Frank F Bond, house physician.

CASE 1—A woman, aged 27 years, was admitted into Westminster Hospital at 4 P.M. on May 19th, 1899. The patient had first noticed a tender swelling on the mucous membrane of the right nostril on the 17th. A few hours afterwards the outer surface of the nostril was red and swollen and by the next morning the rash had extended to both cheeks. There was no history of an abrasion on the skin or mucous membrane. On admission a red brawny swelling was found involving the whole face and extending upwards over the forehead as far as the roots of the hair. Both ears were affected and the rash extended downwards into the neck as far as the level of the hyoid bone. The eyelids were considerably swollen and partially closed. The patient was quite unconscious. The temperature on admission was 103° F. Immediately after admission 10 cubic centimetres of anti streptococcic serum were injected into the subcutaneous tissue of the abdominal wall. The face was dusted with a powder consisting of one part of zinc oxide to two parts of powdered starch and was protected from the air by a lint mask. Half an ounce of brandy was administered every three hours. During the night the temperature ranged between 101° and 103°. The patient was delirious and did not completely regain consciousness until 5 o'clock on the following morning. At 8 A.M. on the 20th the temperature had fallen to 101°, but during the day it rose again, and at 4 P.M. it stood at 104°. At 9.30 P.M. a second injection of anti streptococcic serum (10 cubic centimetres) was administered. The face was still considerably swollen and the eyes were almost closed. The eyelids were bathed with a weak solution of boric acid. On the 21st the temperature fell to 99.8° and did not at any time subsequently reach 100°. The face was not so much swollen and the eyes were fully open. Two more injections of anti streptococcic serum were administered, one on the 21st and one on the 22nd. The temperature fell to normal on the morning of the 22nd and remained at that point. On the 24th the rash had almost entirely disappeared and the face was desquamating in large flakes. The patient was well enough to get up on the 25th.

CASE 2—A girl, aged 16 years, was admitted into Westminster Hospital at 5 P.M. on May 20th, 1899. The patient had first noticed a red tender spot immediately below the right ala nasi on the morning of the 20th. She stated that she had observed no abrasion there previously. The swelling rapidly spread to both sides of the face. On admission there was a red brawny swelling involving the nose, the

upper lip, and both cheeks extending on both sides as far as the prominence of the malar bones. The margins were well defined. The nose and the upper lip were much swollen and there were a few small vesicles on the ala of the nose. The temperature was 100° F. The patient was treated in precisely the same way as was the patient in Case 1. The first injection of anti streptococcic serum was administered at 9.30 P.M., the temperature then standing at 102.2°. On the morning of the 21st the temperature had fallen to 98°. At noon a second injection of 10 cubic centimetres of the serum was given. The temperature at midnight rose to 99.2°, but fell next morning to normal and did not subsequently rise above 99°. A third injection was administered on the 22nd. On the 24th the nose was still a little swollen, but otherwise the rash had practically disappeared. Slight desquamation was taking place along the edges of the ala nasi, the rest of the skin was normal. She was able to leave her bed on the 25th.

Remarks by Mr BOND—Considerable attention having recently been devoted to the treatment of various forms of streptococcus infection by the injection of anti streptococcic serum I have thought that the above cases may be of interest as evidence of the value of this method of treatment in facial erysipelas. The serum is extensively used in the wards of Westminster Hospital and the most successful results have been obtained in cases of erysipelas. On referring to the above cases the following points are noticeable. 1. The rapidity with which an improvement in the patient's general condition is obtained. In Case 1, although the patient was suffering severely from septic poisoning, as evidenced by pyrexia and delirium, within a few hours the temperature was reduced and she was perfectly rational and in three days the temperature had fallen to normal. 2. The fact that the disease may be checked in the early stages by the use of the anti streptococcic serum. Case 2 came under treatment within 12 hours of the commencement of the illness. There was a marked improvement a few hours after the first injection of the serum and within 36 hours the temperature fell to normal. 3. No local symptoms were caused by the injection except a slight tenderness at the point of inoculation which passed off without treatment in the course of a few hours. The injections were administered alternately on the two sides of the abdomen below the umbilicus, this being a site which is but little exposed to pressure. I am indebted to Dr Murrell for permission to publish the cases.

BIRMINGHAM GENERAL HOSPITAL

A CASE OF HYDATID CYST OF THE LUNG TREATED BY INCISION AND DRAINAGE, RECOVERY

(Under the care of Dr R. M. SIMON and Mr LEONARD GANCREB.)

IN the Mirror of Hospital Practice on Oct 15th, 1898, we published the notes of a case of hydatid of the lung in many ways very similar to the following case. The surgical treatment by incision has a very high rate of success, for according to Tuffier's statistics more than 90 per cent of the cases (55 out of 61) recover. Aspiration has frequently proved fatal and is now practically inadmissible. Bond's method of treating hydatids by incision and removal of the cyst without subsequent drainage is not so well suited for the lung as for intra abdominal hydatid tumours.

A young woman, aged 21 years, was admitted into the Birmingham General Hospital on Nov 4th, 1898, under the care of Dr R. M. Simon. The patient complained of cough, shortness of breath, and pain in the right side of the chest. She gave the following history. In February, 1897, while out walking on a very cold morning, she was suddenly seized with acute pain in the right side of the chest over the region of the breast. The pain became less severe, but did not completely disappear for a period of nine weeks. After this the pain recurred, though not severely, every few weeks. In February, 1898, she had another attack of pain in the same region lasting for 12 weeks. From this time the patient remained apparently quite well until a week before her admission into the hospital. The present attack began with pain in the right side of the chest shivering, and sweating

On admission the temperature was 99° F., the pulse-rate was 99, and the respiration rate was 18 per minute. The right side of the chest moved less freely than the left and over an area on the upper border of the fifth rib the percussion note was dull, bronchial breathing was present and vocal resonance diminished. Posteriorly the same physical signs were present over an area extending from the apex of the lung to the spine of the scapula laterally. The dullness extended from the mid line of the sternum on the one hand to the mid axillary line on the other hand. On Nov. 17th an exploratory needle was passed through the second intercostal space anteriorly and some clear watery fluid containing chills but no albumen and no blood-streaks was drawn off. An operation was performed by Mr. Leonard Gamgee on the 9th. An incision was made in the second right interspace antero-laterally. The layers of the pleura were adherent and bulged markedly outwards and on being incised were found to be thickened and to have lying on their inner aspect the typical membrane proper to a hyaloid cyst. Two quarts of clear, watery fluid were let out and a large quantity of fibrinous exudate was removed. Cysts could be felt on the finger being passed into the cavity. During the subsequent progress of the case the discharge was profuse and purulent. Between Nov. 21st and Dec. 3rd the whole of the membrane proper came away. The cavity gradually quieted well at the end of March, 1899. At that time the woman died but the respiratory movements of the right chest were still somewhat restricted.

Remarks by Mr. Gamgee.—Hyaloid cysts of the lung in this common, uncommon, notwithstanding that next to the liver the lung is more often the seat of hyaloid cysts than any other organ in the body. A hyaloid cyst is a rounded sac of soft gelatinous material, the wall of which is apt to give way and to rupture into the air tubes. There are many cases no record of which has been taken place with the not infrequent result that the patient has died on the table. Treatment by aspiration of the fluid in the cavity is not infrequently resorted to but is not attended by success. The layers are found to be non-adherent. It is necessary to detach them together before opening the cyst to prevent the layers from adhering to the pleural cavity. Whether certainly before operation but adhesions may be suspended when the patient has suffered any considerable amount of pain over the region of the cyst. Hyaloid cysts of the lung are generally single and situated in the lower part of the right lung. In the surgical treatment of the condition it is manifest that the prognosis depends mainly on three factors: (1) whether there is one or more than one cyst present; (2) whether the layers of the pleura are adherent or not, and (3) whether the cyst is superficial or deeply seated. I am indebted to Dr. Simon for permission to use the notes taken while the patient was in the medical ward.

Medical Societies.

BRITISH ORTHOPAEDIC SOCIETY.—A meeting of this society was held in the Royal Infirmary, Derby, on May 27th. Mr. Gentles being in the chair. Mr. William Thomas showed a patient in whom the Left Popliteal Nerve had been injured by a kick from a horse and Talpès Equino-Neurorrhaphy having failed he performed fasciotomy. The result appeared to be excellent.—Mr. Tabby, who divided the trunk together when the division occurred close to the trunk broke up into branches.—Remarks were made by Mr. Herbert Jones, Mr. Bennett, Mr. Whithead, and Mr. Freer.—Mr. Carradine read a paper on "The chief points in the operation"—(1) thorough disinfection of the skin, (2) constant irrigation of the wound with an antiseptic, (3) a short incision on the inner side of the arm, (4) division of all the parts in order of their resistance, (5) when necessary linear osteotomy of the neck of the bone.

the os calcis. He said that the special feature of the complete operation is the alteration of the bony axis of the foot without diminution of its length, the inner border of the foot being lengthened.—Mr. Tubby read notes of a case of Spastic Hemiplegia with fixation of the elbow and wrist and pronation treated by carpal radial, and detachment of the pronator radii teres from its insertion. A hole was made in the interosseous membrane and the tendon was passed round the back of the radius to its outer border and fixed, thus reversing the action of the muscle. The patient after six weeks could pick up a pin. The wrist was kept during this time midway between flexion and extension by splints.—Mr. Kebley opened a discussion on Coxa Vara. He described types of the two chief varieties which commence in adolescence. The deformity was rachitic in origin. The partial or even total absence of rachitic changes in other bones localised did rachitic changes tend to be. The various modes or osteotomy which had been carried out or proposed, including a new method, were described. In theory the neck of the bone should be operated on, in practice the trochanteric region was more convenient. Decreased angulation of the neck and shaft formed the striking features on a first glance at the deformity, but the human changes were in the neck itself, especially near the head. In fact, coxa vara was a rachitic deformity of the upper epiphyseal region of the femur. The compensatory genu valgum was common. Mr. Kebley gave attention to a peculiar expression of the rachitic bones, giving prominence to the epiphysis and with and distance to the upper half of the face. Coxa vara in cases of early rachitis was very common, but cases during adolescence were rare. The commencement of the flood of modern literature on the subject dated from Mr. Kebley's own paper in the *Illustrated Medical and Surgical Journal* of Sept 29th 1888. The hypothesis was healthy in these cases. For this and for other obvious reasons excision was not justifiable.—Mr. Mather and Little found great difficulty in accepting the theory that late rachitis was the cause. In none of the extremely rocky skeletons in the London museums was anything approaching the deformities depicted by Kocher and others found. It seemed to be a process *non rachitis*. Charpentier had shown Mr. Tubby also took part in the discussion.

Reviews and Notices of Books.

A Text book of Practical Obstetrics By EGBERT H GRANDIN, M D, and GEORGE W JARMAN, M D Second edition Illustrated with 64 full page Photographic Plates and 86 Illustrations in the text Philadelphia The F A Davis Co 1898 Pp 460 8vo

THIS book aims at providing the student and practitioner with the most important facts of obstetric practice Where any difference of opinion still exists as to the facts the authors have endeavoured to select those which at the present time commend themselves to the majority of obstetric teachers All anatomical, pathological, and embryological details except such as are entirely essential have been omitted The book is divided into two parts—the first treats of Pregnancy, Labour, and the Puerperium, and the second of Obstetric Surgery This arrangement is not without its drawbacks If, for example, a student wishes to know the views of the authors as to the treatment of a case of placenta prævia he will naturally turn first to the index Here he will be disappointed to find no reference to the treatment at all On turning to the reference given under placenta prævia he will find a short and sketchy account of this complication of labour and a further reference to the second half of the book for the details of the treatment recommended In the chapter upon the Induction of Premature Labour cases of placenta prævia are cited as an indication for its adoption and some pages further on the method of manual dilatation of the cervix recommended by the authors in these cases is described If, however, the student wishes to know whether after dilatation of the cervix he had better employ forceps or version he will, we are afraid, be left looking We have entirely failed to find any mention of placenta prævia in the chapter upon the forceps, and yet cases of placenta prævia occur from time to time in which the forceps are a suitable and proper means of delivery We are told in the preface that the busy practitioner, when in want of information, wishes to secure it without the loss of time entailed in searching through a mass of theory and statistics This is a statement upon which we are in entire agreement with the authors It becomes a question, however, whether the practitioner would not prefer to skip the theory and statistics if he could find all he wanted to know about a certain subject in one chapter rather than to search in several different places in a book with a very poor index for what is, even when he has united the several paragraphs, a somewhat incomplete account of a very important condition The book, however, contains some good and clear descriptions of various obstetric operations, even if it does not fulfil the purpose with which it is written Some of the recommendations are necessarily not such as would be approved of by all obstetricians We hardly think that many would follow the practice of opening the abdomen to dilate the contraction ring in cases of inversion of the uterus in view of the various methods available by the vagina for treating difficult cases of this kind The application of forceps above the brim is regarded with disfavour by the authors and yet at the present time we are witnessing a revival of their use under such conditions in preference to version, especially in cases where the practitioner is accustomed to use axis traction forceps They approve of Dürrssen's method of incising the cervix and also of episiotomy In the treatment of occipito-posterior presentations they recommend introduction of the whole hand into the uterus and rotation of the child's body The statement that in cephalotripsy the cranium is crushed in the diameter opposite to that in which the crushing force is

exerted has been shown to be inaccurate by Milne Murray and others In view of the fact that the cephalotribe has been frequently used in the higher grades of pelvic contraction with good results we cannot agree with the statement that it is applicable only in the presence of the minor grades of pelvic contraction We do not gather how the authors would deliver cases of marked pelvic contraction where abdominal section is inadmissible Some of the illustrations are fair but others are very poor The book upon the whole is not one which we can recommend, although it would appear to have met with a favourable reception in its own country

Beiträge zur Augenheilkunde In Gemeinschaft mit Professor Dr E FUCHS in Wien, Professor Dr O HAAB in Zürich Professor Dr A VOSS in Gießen, herausgegeben von Professor Dr R DEUTSCHMANN in Hamburg (*Essays on Ophthalmology* Under the Editorship of Professor FUCHS, Professor HAAB, Professor VOSS, and Professor DEUTSCHMANN) Parts xxxi–xl Hamburg and Leipzig Leopold Voss 1898

THESE essays, which are issued at irregular intervals in pamphlet form and run to about 100 pages each at the cost of 2s 6d or a little more, are very instructive Good writers have been selected and the subjects, which are very diverse, are well and fully treated The following is a list of the last 10 parts with the names of the authors *Luxatio Bulbi*, by Dr Karl Rothenpieler of Laibach, *The Sequelæ of the Treatment of Glaucoma as Observed in 76 Private Patients under the care of Dr Haab*, arranged by Dr Haab's assistant, Dr Sidler Huguenin of Zürich, *Retinal Hemorrhages in Blood and Vascular Diseases*, by Dr E Ammann of Winterthur, *on Horny Degeneration of the Conjunctival Epithelium (Tyloma Conjunctivæ)*, by Dr Best of Gießen, *Essays on the Normal and Pathological Histology of the Lacrymal Passages*, by Dr K Joerss of Gießen, *essays on the Treatment of Trachomatous Diseases of the Cornea and especially of Ulcers*, by Dr L Blumenthal of Riga, *on the Causes leading to Congenital Defects of the Lids*, by Dr Friedrich Geissmar, *on Amyloid Degeneration of the Conjunctiva*, by Dr Hübner of Cassel, *on the Etiology and Treatment of Dacryocystoblenorrhœa*, by Dr N Cahn of Riga, and lastly, an essay entitled, "Further Communications upon my Method of Treatment in cases of Detachment of the Retina and a report on 101 cases of this lesion operated on by my Method," by Professor R Deutschmann of Hamburg

It will be seen that the essays embrace a great variety of subjects and that they constitute monographs of the diseases which they describe The last part, by Professor Deutschmann, is particularly worthy of consideration, since it gives the details of 101 cases of detachment of the retina treated by himself and his colleagues by an operative procedure which he has devised and practised The method of operating consists in transfixing the globe with a narrow double edged knife in such a manner as to make the wound in the globe subconjunctival, the knife passing through the sclerotic, choroid, and retina into the vitreous The point of the knife enters the eye below and to the outer side where the retinal detachment is usually situated and emerges at a somewhat higher level on the inner, lower, and posterior surface In withdrawing the knife it is made to divide the vitreous by lateral movements to a moderate extent The section is performed painlessly under an injection of cocaine solution to which a few drops of perchloride of mercury have been added and the pupil is dilated with atropine Professor Deutschmann has lately conjoined with this method of operation a second proceeding which consists in the injection of the vitreous humour of a

MEMORIAL TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND. Society of Members of the Royal College of Surgeons of England.

THE Committee of this Society take the opportunity willingly and generously granted to them by the Council of appealing to every Fellow and Member of the College to sign the Memorial which will be and over last

The Committee feel that it is unnecessary to enter to a detailed discussion of a matter which has been or less before the profession for fifteen years

For the information of those who are not fully acquainted with the question at issue between the Council and the Members of the College, it may be orally stated as follows —

1 The Council is the governing body of the College and assesses absolute powers

2 The Council is elected solely by the Fellows under the charter of 1813.

3 According to the last Calendar there are 17,199 members and 1195 Fellows

4 The property of the College is by the original Charter 1600 entirely vested in the Members, for whom the Council acts as Trustees

5 The Fellows, as such have no interest in the College property except in so far as they are also Members

6 As shown by the balance sheet by far the largest source of the College income is derived from the Members' payments

7 The Council has now to deal with many matters affecting the welfare and discipline of the Members, with some of which it has shown itself to be imperfectly acquainted.

8 The Members, therefore, propose that a small increase be made by Charter in the number of the Council and that Members shall have the right of election to these additional seats

9 At every annual meeting of Fellows and Members (instituted in 1831) this or some similar proposal has been

carried practically unanimously, and a petition in its favour was signed by nearly 5000 members and presented to the Privy Council

10 The Council have twice taken a poll of the Fellows on the question, but on neither occasion has an absolute majority voted against the proposal, while many were in its favour

11 It is generally felt that it would be a gracious act on the part of the Council to embody some compliance with the Members' wishes in the new Charter for which they are now about to apply, and that this is a most opportune moment to effect a termination of the controversy

Mr Jonathan Hutchinson, F.R.S., F.R.C.S., ex-President of the College, says, in a letter headed "The College of Surgeons and its Members" —

We are told that "Members have no right, legal or inherent, to a share in the government of the College," Now, without doubting the law of the matter, may I still ask whether they do not possess a moral right—that is, a right founded upon the justice of the case? If a *de novo* scheme of government were to be devised for such a body as the College now is, with its thousands of Members and hundreds of Fellows, can anyone believe that the former would be wholly excluded from power?

Let me, however, very seriously ask Has not the time arrived to put aside all arguments based upon "legal or inherent rights" and definitions of the "body-corporate," and ask simply whether or not it will be for the good of the profession that the Members of the Royal College of Surgeons should be admitted to some share in its government? For myself, most unhesitatingly do I believe that the advantages would be great

present system puts the management of the affairs of the College wholly in the hands of operating or, in other words, of hospital surgeons. Now, to them very suitably appertains the chief share but not the whole. The questions with which the Council has to deal require wider sympathies and first-hand experience of a more extended kind than are possessed by any one class. It is all very well

to suggest that the College has no other than merely surgical objects and to try to impute to reformers the desire to make it a "political" tribunal. However willing we may be to leave all social and State questions to the British Medical Association and to wash our hands of "politics," the thing is as impossible as it is inadvisable. The College of Surgeons will always, it is to be hoped, take a foremost place in all schemes for the development of medical education. It will still be consulted by the Government of the day on many questions, such, for instance, as the Midwifery Bill and the Vaccination Laws. It cannot, if it wishes, shroud itself in privacy or reduce itself to insignificance. That it should deal with such matters as I have mentioned with effect and judgment it seems to me most desirable that it should have at its Council board men well informed in their details and at its back the sympathies and support of a large body of the profession. Its organisation ought to be widely and not narrowly representative.

The admission to its Council of half a dozen well informed men familiar with the details of family practice and with the educational wants of the great bulk of the profession would, I feel sure, be a distinct gain. Nor would it do any

real injury to the status or privileges of the Fellowship. I doubt if anyone ever seeks the Fellowship for the sake of the vote which it gives and whether the number of candidates would be in the least diminished by the change. The diploma of the Fellow will still carry superior privileges as to the eligibility and voting, and it will always remain an essential passport to most hospital appointments. Everyone will still continue to recognise in the letters F.R.C.S. a guarantee that their possessor has been specially trained as a scientific and operating surgeon. There is no real ground for fear that the two grades, Membership and Fellowship, will ever be more confused together than they are at present. Already it is to be noted the College has made Members eligible for some of its offices—as examiners, professors, and prize takers. Let us not uselessly prolong a half hearted controversy the final end of which may be easily foreseen. To concede graciously is the art of all concession, and the longer this matter is kept in debate the less will be the gracefulness of the final yielding. I am impressed, therefore, with the conviction that the admission of a limited number of Members to the privileges which they seek will be to strengthen the College itself and to increase its usefulness to the community.

All Fellows and Members who can possibly do so are specially urged to attend a

General Meeting which has been summoned at the College for Wednesday week, July 5th, at

3 p.m., to discuss the terms of the proposed Centenary Charter

Any Member who is desirous of giving practical support to the efforts of this Society to obtain a reasonable reform will oblige by filling up the subjoined and returning it together with the signed Memorial—

I desire to join the SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, and I enclose the Annual Subscription of Two Shillings and Sixpence.

To the President and Council of the Royal College of Surgeons of England

GENTLEMEN,

We, the undersigned Fellows and Members of the College, desire to make the following representations to you

We have heard with satisfaction of your intention to apply for a supplementary Charter in order to fittingly celebrate the Centenary of the granting of the original Charter in 1800. We cordially endorse the proposal that you should obtain powers to confer the Fellowship of the College on persons of distinction who are not Members. We further very sincerely wish that the celebration of this Centenary may be marked by the harmony and good feeling between all parts of the Corporation which ought to distinguish such an occasion. We therefore very respectfully suggest to you that an extremely favourable opportunity now presents itself for the satisfaction of that desire which lies at our hearts during the century, and especially during the last 75 years, been expressed by a large number of the Members of the College—viz, that they should be represented on the Council.

We do not intend to repeat the various arguments in favour of this proposal, as these must be well known to you, but, in the words of a former Petition, "we submit that it would be both equitable and politic that the Members should have a voice in the conduct of a Corporation of which they are, and always have been, numerically and financially the majority."

We would point out that this statement has been endorsed by at least one former President, by many Fellows, by some 5,000 Members, and by the entire Medical Press, that it has never been seriously challenged, but that the objections to it have rested mainly on the ground of the apparent interference with the prerogative of the Fellows. We are convinced that the difficulties in the way are by no means insuperable, and we earnestly trust that the Council will make the settlement of this long standing controversy a prominent part of the Centenary celebrations.

We respectfully bring this matter under your notice at the present time, in full confidence that you will deal with it in an equitable and dispassionate manner, and in accordance with the general sense of the profession at large.

young rabbit into the globe. For this purpose Luer has constructed a knife for him which is perforated like a wisp of fluff lengthwise and has a linear opening near the extremity to which he has given the name of "Messer-kannula" or "knife cannula." Connected with the base of the knife is a syringe. In using this instrument Professor Deutschmann endeavours to drive the rabbit's vitreous into the per-retinal space—that is to say, into the space between the detached retina and the shrunken vitreous. Professor Deutschmann appears from the reports of his cases to have met with encouraging success and though in many of his cases no benefit accrued to the patient in others the improvement was marked and permanent.

An American Text-book of Genito-Urinary Diseases, Syphilis, and Diseases of the Skin. Edited by L. BORSTOV BAKG, M.D., Consulting Surgeon to St. Luke's Hospital and the City Hospital, New York, &c., and W. A. HARDARVAX, A.M., M.D., Professor of Diseases of the Skin and Syphilis in the Missouri Medical College, St. Louis, &c. Illustrated with 300 Engravings and 20 full page Coloured Plates. London: The Rebmam Publishing Co. 1898. Imperial 8vo. In two volumes, pp. 1229. Price 42s.

THERE is no natural union between diseases of the genito-urinary system and diseases of the skin, but custom has sanctioned the association of the two, both in professors and in treatises, the connecting link is syphilis, which may be said to belong to both, yet as these two classes of diseases are essentially distinct it would be well to deal with them in separate treatises. These two handsome volumes belong to the now well known series of American text-books issued by the Rebmam Publishing Company and they are fully up to the high level hitherto maintained by that series. The editors have been assisted by 45 writers in the arduous work of preparation of this large treatise, and their names are sufficient to guarantee that the contents fully represent of this work the latest and the most important contribution is an article on the Diseases of the Male Urethra, by Dr. G. Frank Lydson. This occupies nearly 130 pages, and the very full account of strictures deserves especial mention. Urethral fever is considered by the author to include six forms of morbid phenomena, which, however, may be combined in different ways in different individual cases. The six forms are—(1) a nervous rigor, not succeeded by fever, caused by slight surgical shock, (2) traumatic fever, due to excessive reaction from surgical shock, with decomposition of fibrin-ferments, (3) toxemia following severe shock with perversion of the urinary secretion, and reflex inhibition of the function of the kidney, (4) septicæmia and pyæmia, (5) chronic urinary fever attended upon obstructive diseases of the urinary organs, and (6) mixed forms. We agree that under the head of urethral fever many different diseases are included, but we are inclined to think that Dr. Lydson's classification is unnecessarily complex. There are probably three elements which may in any case be combined in any proportion, the three elements are—(1) a nervous element, irregular activity of kidneys damaged by preceding disease. By these three elements can be explained all the varied phenomena met with in individual cases.

Dr. J. William White and Dr. Alfred C. Wood have contributed the article on Diseases of the Prostate and describe very completely the advantages and disadvantages of castration for hypertrophy of the prostate, a method of treatment which was introduced by one of the authors (Dr. White).

The articles on Syphilis occupy 140 pages and have been written by seven authors. The description of the syphilitic

Synopsis of Surgery. By R. F. TOLIN, F.R.C.S. Ireland. Surgeon to St. Vincent's Hospital, Dublin. London: J. & A. Churchill (Dublin) Kegan and Co. and W. McGee. 1898. Pp. 277. Price 6s. 6d.

THE material of which this book is composed was originally issued by the author to the members of his clinical class in the form of leaflets and they were intended in the first place to systematise the teaching and in the second place to save the students taking notes. There is much to be said for the author's contention that clinical teaching should be more systematic than it too often is and we think that notes like those contained in this volume might prove very useful. Of course, a student should fully understand that a volume like the present is no adequate substitute for one of the ordinary text books on surgery, but used as an addendum this little book may readily prove of service. The statements are clear but brief and may make a more lasting impression on a student's mind than more verbose descriptions. The work is very neatly and strongly bound and the inter leaves of plain paper are convenient for students' notes.

The Factory Laws of European Countries. By E. BAUM. BROOKS London. Grant Richards 1898. Pp. 62.

THIS is a very useful, systematic, and brief compilation of the legislation of the different European countries in so far as it relates to the hours of labour, and childrean, and the work of women, young persons, and children, and restrictions enforced in regard to unwholesome industries. In a word, we have a bird's-eye view of the labour protective legislation of Europe. We can see at a glance which are the most progressive and which are the least advanced among the nations of the Continent. Of course, such a book can only be used as a sort of guide and basis for the study of the grave problems involved. It does not suffice to know what the laws of a country are, we must also be well informed as to the social condition of the country and as to the manner in which the law is applied, but such details would fill volumes. The little book before us deals only with the laws, though here and there a hint is given that the knowledge of the law by itself is not enough. Thus undoubtedly Switzerland, among the most advanced nations of Europe in regard to labour legislation and yet there are practically no laws controlling the work in mines. This, however, does not mean that Switzerland is behindhand but simply that there is hardly any mining industry in that

country. On the other hand, it has been truthfully, if some what sarcastically, stated that the "exploitation of the foreigner" is the principal industry of Switzerland. This, of course, means the employment of an immense number of servants and waitresses in hotels, restaurants, &c. In other countries there are hardly any laws protecting this form of domestic work, but the Federal law gives power to the cantonal authorities to decide what places shall be brought under the factory legislation and the law of the canton of St Gall especially extends such Acts to cafés and hotels. Altogether this is a useful little book, so brief and full of information that it might be called a dictionary of labour legislation.

LIBRARY TABLE

The Temples and Ritual of Asclepios at Epidaurus and Athens. By RICHARD CATON, M.D. Edin., F.R.C.P. Lond. Reprinted from "Ostra Merseana." 1899. Pp. 42.—Lovers of medical archaeology owe a debt of gratitude to Dr. Caton of Liverpool for the publication in book form of the two lectures delivered by him last summer at the Royal Institution of Great Britain. Written in an attractive style and illustrated on almost every page with photo-prints of buildings and statues, this little volume is an admirable handbook to historical localities of exceeding interest. Lecture I deals mainly with architectural and structural details of temples and shrines, the last of the illustrations showing the seats reserved in an Athenian theatre for the priest of Asclepios and the priest of the Muses. In Lecture II Dr. Caton discusses the ritual of the shrines and the accommodation and treatment of the sick who frequented them. The similarity of human nature in all ages and the credulity of patients twenty centuries ago are here attested by translations of inscriptions recording many cures too marvellous to be true. Dr. Caton's tour in Greece has supplied him with a congenial theme and the illustrations from photographs taken by himself add to the vividness of his descriptions.

Lippincott's Pocket Medical Dictionary. Edited by RYLAND W. GREENE, A.B. Philadelphia and London. J. B. Lippincott Company. Pp. 421. Price 5s.—This little book deserves recommendation as a useful work of reference. The type being small but clear and the paper thin but good the editor has been able to condense a large amount of information into small compass. In general a line is given to each of the 20,000 words explained, but under certain special headings this allowance is greatly exceeded. For instance, the varieties enumerated and defined under Bacillus and Bacterium occupy about 160 lines (three pages). In a dictionary for the pocket portability is an essential quality. Those who require a more comprehensive work will find a very complete collection of terms used by medical and biological writers copiously explained in Lippincott's Medical Dictionary (1154 pp. in double columns) published in 1897. The two dictionaries, the large and the small, are by the same editor.

Official Year book of the Scientific and Learned Societies of Great Britain and Ireland. London. Charles Griffin and Company. 1899. Price 7s. 6d.—This is the sixteenth annual issue of a work which is something more than a handbook of reference, inasmuch as it forms an index of the scientific work of the year as well as affording information with regard to the names of officers, the times of meeting, conditions of membership, &c. The various scientific societies are conveniently arranged under 14 heads. Medicine occupies 47 pages, as compared with 275 pages devoted to other and cognate branches of science. There is a very complete index and the book is a really useful publication.

Analytical Records

FROM

THE LANCET LABORATORY

UROSIN

(ZIMMER AND CO. FRANKFURT-ON-THE-MAIN. AGENTS: WIDLIN, WANN, BROICHER, AND CO., 33, LEIDL STREET, E.C.)

UROSIN is the interesting compound of quinic acid with lithia. As is well known quinic acid is the chief organic acid of cinchona bark, it occurs also in the bilberry plant and in some fruits, as the strawberry and cherry. Lithia in association with quinic acid is said to prevent the formation of uric acid, thus differing from other drugs regarded as of value in gout which at best claim to be solvents of uric acid. Lithium quinate is a light white crystalline substance responding readily to the reactions for both quinic acid and lithia. Thus it burns with a brilliant crimson flame and yields iodiform on treatment with potash and iodine. An interesting clinical contribution on the treatment of uric acid diathesis by quinic acid appeared in the *Berliner Klinische Wochenschrift*, 1899, No. 14, in which it was shown by the author, Dr. J. Weiss of Biele, that quinic acid possesses the property of considerably decreasing the formation of uric acid in the organism. According to this the compound of quinic acid with lithia—namely, urosin should be of a promising character as a therapeutic agent in gouty affections. The tablets examined contained each seven and a half grains of the drug. Urosin is also supplied in the form of effervescent tablets and a pleasant way of exhibiting the drug is in aerated water.

OLD COGNAC BRANDY

(EDWARD ARCHER AND CO. GREAT MALVERN)

The analyses of the two specimens of Cognac brandy submitted for analysis, which are distinguished by different labels, were as follows. No. 1 alcohol by weight 39.80 per cent, by volume 47.13 per cent, equal to proof spirit 82.59 per cent; alcohol in volatile ethers, 0.0193 per cent, extractives, 0.62 per cent, mineral matter, 0.01 per cent, acidity reckoned as acetic acid, 0.033 per cent. No. 2 alcohol by weight 39.30 per cent, by volume 46.59 per cent, equal to proof spirit 81.64 per cent, alcohol in volatile ethers, 0.0184 per cent, extractives, 0.71 per cent, mineral matter, nil, acidity reckoned as acetic acid, 0.031 per cent. Both specimens possessed a desirably soft and mellow flavour characteristic of matured spirit. Specimen No. 1 is probably the older of the two since it contains a slightly higher percentage of Cognac ethers than No. 2. The features presented in this analysis are satisfactory and, coupled with the general characters of taste and smell, warrant the recommendation of both brandies for medicinal purposes. Both specimens evinced an excellent development of those fragrant and aromatic characters peculiar to genuine and matured brandy.

EFFERVESCENT CARLSBAD WATER LENTIFORMS

(W. R. WARNER AND CO. PHILADELPHIA. AGENTS: F. NEWBERRY AND SONS, KING EDWARD STREET, NEWGATE STREET, E.C.)

These lentiforms contain, of course, sulphate of soda as the chief representative salt of the Carlsbad waters. They afford a briskly effervescing draught when dissolved in water. Their convenience in use is obvious.

TOILET AND MEDICATED SOAPS

(EDWARD COOK AND CO. EAST LONDON SOAP WORKS, BOW, E.)

The list of this firm is replete with every variety of soap and of the specimens which we have examined in THE LANCET laboratory all come correctly under

of meat and may thus exercise a favourable effect upon the processes of nutrition. The wine under examination possessed a pleasant malty flavour and it is evidently prepared with a sound port wine

(THE SOUND SOUP SYMPLECTIC OLD VICARAGE HOUSE, WALSHAM.)

Under this curious title is comprised a dry soup powder. Microscopical examination makes the composition of the powder pretty obvious. It is composed of pulse food cereals and vegetables. On soaking in water and subsequently making up to a pint and gently boiling for half an hour a soup of excellent flavour, due largely to a careful choice of aromatic herbs, &c, is obtained. It is said that no less than 20 ingredients are used. The powder is excellent for the easy preparation of a cheap and nutritious soup while also affording a suitable adjunct for stews or "stock."

BLACKBERRY BRANDY

(O WRIGHT AND SON, WILKINGTON)

The analysis of this preparation, which may be regarded as a new liquor, was as follows: Alcohol by weight 22.08 per cent, by volume 26.95 per cent, equal to proof spirit 47.23 per cent, extractives, and sugar, 15.33 per cent, and mineral matter, 0.15 per cent. The preparation has a very agreeable flavour of the blackberry and is deliciously fragrant. On adding perchloride of iron a black colour is produced characteristic of tannin compounds. The brandy used is said to be old French Cognac and the flavour is decidedly soft, which to some extent is proof of its maturity. The topic properties of the preparation may be referred to the peculiar principles of the blackberry

New Inventions.

THE "GERBAP" APPARATUS

This apparatus is designed for an anatomically unimpairing the air of oloases, lavatories, and other places where such procedure is desirable with a suitable deodorant and disinfectant. At the same time a self acting arrangement is also attached so that the contents of the closed pan are to some extent rendered inoffensive. Once fitted the apparatus gives no trouble and works, as we have found in practice, easily and factually. Over the door of the lavatory is placed a cylinder into which a piston with a plunger attached is fitted at right angle. The act of opening the door drives the plunger from one end of the cylinder to the other and thus pushes a column of air through a small pipe into a closed box. The box contains a certain agreeable antiseptic fluid which by means of an ordinary spray apparatus is diffused into the air in the form of fine spray by reason of the force of air acting upon the fluid when the door swings. The action is thus perfectly automatic. Instead of the door serving to force a column of air into the diffuser in this way the lid of the closed seat may obviously be made to bring about the same action. The apparatus is very cleanly in action and produces a very agreeable effect upon the air of the lavatory, and without which lavatories and water-closets chambers often lapse is only too well known, but by means of this ingenious contrivance such an objectionable condition is easily avoided. The Gerbap Company, of 6, Philip Lane, E.C. 5, have, we understand, fitted this apparatus to the lavatories of several corridors trains and of hotels, restaurants, and other places. The apparatus is kept in working order by the company for a small annual charge.

The quality described—namely, pure

The soap basis is of excellent quality, in which fat and alkali are balanced as closely as skill and scientific manipulation in manufacture will allow. The soap known as "Cam-

bath" is a very useful and agreeable soap for the bath. As its name implies it contains camphor, certain

aromatics, and a well known antiseptic which is soothing and beneficial to the skin. In some measure it is a

preventive against the attacks of insect pests. It has a pleasant, stimulating action upon the skin and is an agree-

able and effective detergent. "Myer's" soap is slightly

superfatted, the fat employed for this purpose being readily

absorbable by the skin. On examination it showed an excel-

lent degree of purity. "Bassam Violet" toilet soap con-

tains an equally excellent and antiseptic soap basis but in

addition it is delightfully scented with a fragrant perfume. The

special antiseptic soap made by this firm deserves greater

attention than has hitherto been paid to it by surgeons and

others. It contains the double iodide of potassium and

mercury, which, according to bacteriological experiments, has

even stronger germicidal powers than corrosive sublimate.

As is well known the red iodide of mercury is com-

pletely soluble in a slight excess of potassium iodide. The

resulting double iodide is quite compatible with soap,

whereas corrosive sublimate is incompatible with soap.

A bin iodide toilet soap is thus prepared as is a special

antiseptic soap for medical purposes containing from 7

to 3 per cent of mercuric iodide. Lastly, we have

examined a specimen of "hygienic tooth" soap in which

are combined antiseptics, astringents, aromatics and

antacids in suitable proportion forming a very agreeable

soap compound for the cleansing of the teeth. Here,

again, the soap basis is of the purest character

(1) ORGICAL FOOD LOZENGES, (2) ASPIRIN SPONGE

AND (3) ANTISEPTIC VAGINAL CAPSULES

(SQUIRE AND SONS 413, OXFORD-STREET W)

MEAT AND MEAT WINE

(LAWSON AND WATTS 48, ST ALBY STREET LIVERPOOL)

The analysis of this wine was as follows: Alcohol by weight 14.91 per cent, by volume 18.36 per cent, equal to proof spirit 32.19 per cent, and mineral matter, 0.25 per cent. The quantity of protein found by the bromine method was 0.042 per cent. This bears out what we have so frequently stated, that in preparations of this class there is, as a rule, very little real nutritive matter for the simple reason that the products of meat are not soluble in fluids containing as much alcohol as does this wine. But such preparations may contain the same amount of nutritive matter as the wine.

The analysis of this wine was as follows: Alcohol by weight 14.91 per cent, by volume 18.36 per cent, equal to proof spirit 32.19 per cent, and mineral matter, 0.25 per cent. THE LANCET.

LONDON SATURDAY, JUNE 24, 1899

THE President of the General Medical Council did well to direct the preparation of a narrative of the case of HUNTER v CLARE and the Council did equally well to have it inserted in the minutes which are now public property for the use of all who are interested in the case. For the case is one of which it is difficult to get a perfectly impartial and unprejudiced impression, as all our readers know who have followed the correspondence, leading articles, and signed communications which have appeared in our columns. The sad death of Mr HUNTER in the middle of the litigation imported into it an element of pathos which must not be allowed to affect our judgment, but which has certainly had its influence upon many members of the profession.

The case divides itself roughly into two stages—that in which the use of the title "M.D." on the strength of possessing a medical degree from the Jefferson Medical College, U.S.A., was the chief subject of complaint, and a later stage in which this charge dropped out and the use of the titles "Physician and Surgeon" became the only matter in dispute. To the charge of using the title "M.D." no further reference than this need be made. Mr HUNTER was a genuine M.D. of the Jefferson Medical College of Philadelphia,¹ and this institution is duly recognised by the General Medical Council as one granting proper scientific degrees which are even registrable under certain conditions.² On the second charge the Society of Apothecaries of London came to the help of Mr HUNTER, who now got into a fighting humour, for he said on Sept 30th, 1897, "As I am being 'backed up' I mean to fight now to the end." Such a humour is somewhat infectious and the Penal Cases Committee of the General Medical Council caught the fighting spirit with an alacrity that might well have been reserved for a more fitting case. Acting on the suggestion of Mr MUIR MACKENZIE that the case "raised in a convenient form issues of law and fact" the committee sent the case to the General Medical Council to consider whether it would be advisable for the Council to institute a prosecution. The Council after hearing the opinion of Mr MUIR MACKENZIE resolved on the prosecution. When the summonses came to be applied for it was found that the use of the title "M.D." had been discontinued, whereupon summonses were applied for in regard to the use of the titles of "Physician and Surgeon" respectively. The magistrates considered the case governed by the well known case of Regina v Baker and fined Mr HUNTER £5 for using the title of "Physician." Mr HUNTER'S counsel asked the magistrates to state a case, which they agreed to do. The summons in respect of the

user of the title "Surgeon" was not proceeded with. The magistrates then stated a case for the opinion of the Court of Queen's Bench. After setting forth the facts the questions of law stated were (a) whether or not the appellant (Mr HUNTER) holding the title of L.S.A. and being registered as such is authorised to take or use the name and title of "Physician" in the manner the appellant used it, (b) whether, on the facts herein stated, the magistrates were right in finding that the appellant so described himself wilfully and falsely within the meaning of 21 and 22 Victoria, Chap 90. As our readers know,³ the judges, Mr Justice LAWRENCE and Mr Justice CHANNELL, decided in answer to the first question, (a), that the magistrates were right and that Mr HUNTER was not right in using the title of "Physician." As to the second question, (b), they decided that the magistrates were wrong. They quashed the conviction on the ground that Mr HUNTER had some colour or title to use the description which he did use, especially having regard to the directions issued by the Society of Apothecaries.

Such are the facts of this case on which so much strong feeling has been expressed that the outlines of the picture have been obscured by the intrusive colouring of some of the details. The discussion of the case in the General Medical Council threw no additional light upon it, but neither the lawyers of the General Medical Council, its Penal Cases Committee, the Council itself, nor the Society of Apothecaries of London can be held quit of blame. We think, as the judges thought, that the answer of the Society of Apothecaries to Mr HUNTER'S inquiry whether the diploma of the Society entitled him to use the title of "Physician" was very uninforming. It runs as follows—

"The L.S.A. (1886) can call himself by any title which he prefers to adopt denoting the right to practise medicine, surgery, and midwifery, provided that he does not directly or indirectly assume a title conferred by another licensing body or university."

Again, we think that a registered member of the profession labouring under a definite accusation is entitled to more definite answers to questions as to what he may do than those which Mr HUNTER received from Mr FARRER, though it must be admitted that the tone of Mr FARRER'S letters was kind, and constantly recognised as such by Mr HUNTER. The General Medical Council is not a legal court but rather a body from which a medical man has a right to expect some friendly guidance and more than a bare answer as to what he may not do. It is possible that a little more explicitness on the part of the Society of Apothecaries or Mr FARRER might have saved Mr HUNTER the worry of a prosecution which according to some affected his health fatally. But it is difficult to be sure on this point. A perusal of Mr HUNTER'S letters does not give us the impression that he was much averse to a little fighting. He believed that he was doing right in calling himself a "physician" (as many good lawyers do in spite of the recent judgment) and he had the courage of his opinion, and when the Society of Apothecaries came quickly to his support we believe that he was ready enough to go on. The General Medical Council and the Penal Cases Committee must be blamed for allowing themselves

¹ THE LANCET April 22nd, 1899.
² The current Medical Register p. 85.

³ THE LANCET, Jan. 28th 1899 p. 257

mentioned, some of the work which has there been carried out being valuable contributions to medical science.

Dr WILSON pays due attention to medical literature. Two publications in particular the whole medical world is indebted. When a writer wishes to refer to the literature of any medical subject he naturally turns over the pages of either the "Index Catalogue of the Library of the Surgeon General's Office of the United States Army"—a most stupendous work—or those of that unique and most useful of medical literary productions the "Index Medicus." Too high praise cannot be given to the industry and perseverance necessary for the compilation of these volumes, as a record of medical literature they are most complete and their value can scarcely be over rated. The work now in course of publication, "The Twentieth Century Practice," we have frequently referred to in our columns in favourable terms. Many excellent text books have also emanated from American authors. OSER'S "Principles and Practice of Medicine" can successfully rival any other similar manual, and many works of equal excellence on special branches of medical science could also be mentioned, bringing well earned renown to their writers. Turning to American journalism we cannot speak in such high praise. Some of the weekly publications are of first-class quality, such as the journals of Boston, New York, and Philadelphia, and the journal of the American Medical Association, but on the other hand there are numerous other monthly and quarterly "journals" appearing in various parts of the United States the disappearance of which would be a loss to no one. The contents are mainly extracts from other papers and the profuse interleaving of advertisements is highly objectionable. It is probably mainly due to this feature that many of these periodicals owe their existence. Then there is another class of publications appearing under various fantastic titles which are issued solely as advertisements of some firm of druggists or even as a "pull" of a particular drug, and are scattered broadcast, at any rate throughout this country. To the undersignability of such action we have already referred, the means entirely defeats the object for which they are distributed, and the great majority of the pamphlets find their way into the waste-paper basket without the cover being removed. The publishers of these advertisements would be well advised to close the distribution of such books, for they not only bring the preparations which they praise into disrepute, but likewise tend to lower the prestige of the American medical press generally.

Dr WILSON dwells at some length on the influence which the American Medical Association should exert on medical education and medical ethics. Great advance has already been made in most of the American medical schools the course of study being closely approximated to that which is required in the English schools of medicine. A few years ago a sad state of affairs existed in some of the States, but this has fortunately been altered. Much, however, remains to be accomplished, and Dr WILSON asks for more uniformity in the requirements for admission to a degree, a systematic treatment of nomenclature by ALCOCK, also received well-merited praise. In surgery the names of O DWYER, BENJ. ALFRED RICHARDSON and others will always hold a high place. In this connection the reports issued from the laboratories of the Johns Hopkins University must be

too easily to be induced to try to get a somewhat small question of law settled. As a result the judgment established neither side and will have in its turn to be reconsidered. We trust that all will recognise that the matter is now one which should be discussed apart from personalities. Not a scrap of evidence has been forthcoming that the General Medical Council treated Mr. HUTCHINSON in any way maliciously. They selected him with some intelligence as a man whose prosecution would settle a vexed point. Mr. HUTCHINSON was prosecuted, but the point remains vexed. As further controversy is therefore inevitable we hope that the medical profession will rather look forward to a happy solution than backward at past errors of judgment. The medical profession is no longer divisible mechanically into apothecaries, surgeons, and physicians, and the sooner law and the interpretation of the law are brought to recognise this equality before the law of all registered medical practitioners the better.

It was in defence of this principle that Mr. HUTCHINSON fought every whit as much as in assertion of his private beliefs, and while registering here our sense of his courage and of the peculiar sadness of his death we would remind our readers that their contributions are earnestly solicited in our columns to a fund for his sorrowing widow.

IN THE LANCET of June 10th we published the abstract of an Oration on Medicine by Dr J. O. WILSON of Philadelphia, entitled "A Century of Medicine in America." The address was appropriately delivered at the fifteenth meeting of the American Medical Association, held at Columbus, Ohio, on June 7th. There is much that is interesting in Dr WILSON'S remarks in addition to his comments on the advance of medical science in America. He referred to the introduction of vaccination and the introduction of the stethoscope and auscultation, to Virchow's great work on "Cellular Pathology" as based upon Physiological and Pathological Histology, to the discovery of LISTER, and to numerous other discoveries which have proved landmarks in medical science. But the main object of the discourse was to note the position of the United States in regard to modern medicine. The orator cannot be accused of exaggerating the work done by American investigators, his remarks showed good and calm judgment. He remarked that "the latest work of investigators in every field of research and in every country is quickly before us and we give something in return," and he drew attention to the investigations of Professor J. K. MITCHELL, who was "the first to approach in a scientific spirit the nature of infective disease and particularly in malarial fever," and to the confirmation in America of LAVANNA'S observations on the malarial parasite by COUGHLIN, OSER, and THAYER, who was also referred to. The work of BRAD in the treatment of enteric fever by systematic cold bathing, and the [successful] treatment of neurasthenia by ALCOCK, also received well-merited praise. In surgery the names of O DWYER, BENJ. ALFRED RICHARDSON and others will always hold a high place. In this connection the reports issued from the laboratories of the Johns Hopkins University must be

among those boards by which the licences may be transferred. All this is highly desirable, as are also many other recommendations to be found in Dr WILSON'S paper. The last proposition, however, is the most original—namely, that the American Medical Association "should exert its influence to secure the appointment of a Secretaryship of Public Medicine, the portfolio of which should be assigned to a medical man, to the end that the President may be promptly and authoritatively advised concerning technical questions of vital importance to the welfare of the nation." Such an appointment presumably would be analogous to what we have often suggested in this country, namely, that of a Minister of Public Health.

CEREBRO SPINAL fever, or, as it is more usually termed, "epidemic cerebro-spinal meningitis," is a disease of which fortunately we have had scanty experience in this country. Dr J. A. ORMEROD, writing in Professor OLIVFORD ALLBUTTS "System of Medicine" gives an account of the outbreaks which have occurred in the United Kingdom since 1807. None of these has been widespread, but, as the same writer points out, there are many reasons nevertheless why we should not neglect the study of the malady: its historical and geographical interest is great, its exact etiology is still a matter of dispute, and a country hitherto comparatively immune cannot expect always to escape epidemics in the future. In this week's issue we publish an abstract of the Cavendish Lecture on the Etiology and Diagnosis of Cerebro spinal Fever, delivered before the West London Medico-Chirurgical Society by Dr OSLER, Professor of Medicine in the Johns Hopkins University, Baltimore. Dr OSLER'S powers of observation are so well known that great weight will necessarily be attached to the conclusions at which he has arrived and there are several points in his lecture which materially add to our knowledge of the etiology and diagnosis of the disease.

Dr OSLER first refers to the points of resemblance which exist between cerebro-spinal fever and pneumonia. The general relations are the same in both diseases and the two may prevail together. The abrupt onset, the great frequency of herpes in both, the leucocytosis, and the almost identical characters of the fibrino-purulent exudate in the two diseases (as drawn attention to by Dr NETTER) and the frequent complications of pneumonia in epidemic cerebro spinal fever and of meningitis in pneumonia are additional points of interest. But, on the other hand, Professor LEICHTENSTERN points out various differences, such as that pneumonia is a disease spread over the entire earth and appears at all times, whilst cerebro-spinal fever is very rare and in many countries is as yet unknown, also that pneumonia attacks every age, whilst epidemic meningitis is a disease which affects children and young people.

Especial interest will be taken in Dr OSLER'S remarks on the bacteriology of cerebro spinal fever. Dr ORMEROD in his article says that bacteriologists are at a disadvantage in this matter because since their science has established itself there have been no large epidemics of meningitis and therefore their researches have been limited to certain

minor outbreaks. No doubt it is owing to these circumstances that the conclusion was arrived at that the organism associated with epidemic meningitis is identical with, or closely related to, that which is responsible for croupous pneumonia. Professor WEICHELBAUM, however, more than 12 years ago described a diplococcus with special cultural peculiarities which he regarded as the specific organism of the epidemic form of the disease. These observations were confirmed by Professor JAEGER in 1895 and have since been corroborated by other investigators. This organism is variously known as the meningococcus and the diplococcus intracellularis meningitidis, and according to Dr OSLER is now regarded as the specific cause of the disease. The meningococcus has usually a diplococcus form and lies within the polynuclear leucocytes, hence the definition *intracellularis*. It is found in the cerebro-spinal exudate, rarely elsewhere in the body, but it has been isolated from the blood, the pus from the joints, the pneumonic areas in the lungs, and the nasal mucus. Dr OSLER freely criticises the writings on this subject of Dr NETTER who maintains that the pneumococcus can, without doubt, cause meningitis, we are inclined to agree with Dr OSLER that Dr NETTER'S position is illogical, for the latter towards the close of his article in "Twentieth Century Practice" states that certain peculiarities "prevent us from concluding that the two diseases (i.e., pneumonia and cerebro-spinal fever) are absolutely identical." If Dr OSLER'S contentions are right as regards the pathogenic organism a great step has been gained in diagnosis and this is accentuated by the procedure known as "lumbar puncture," introduced by Professor QUINCKE, this enables us to make a prompt decision as to the existence of meningitis, assistance being derived not only from the bacteriological examination of the fluid but also from its general character. If the operation is carefully performed fluid is nearly always obtained. It may be clear, turbid, purulent, or more rarely of a "brownish yellow," or quite bloody. In a great majority of the cases when meningitis is present the fluid is turbid. Several observers, however, have noted that the fluid may become clear in the intermissions of disease or a clear fluid may be obtained from a puncture in the second lumbar interspace while lower down a turbid fluid may be withdrawn. Dr WENTWORTH claims that within certain limits there is some relation between the degree of turbidity of the fluid and the severity of the symptoms and Dr OSLER states that this was borne out by his experiences. The number of the organisms found bears no constant relation to the intensity of the symptoms.

We have no space to comment on Dr OSLER'S interesting remarks on sporadic cerebro spinal fever. Cases occur from time to time in our hospitals which afford interesting studies from clinical, bacteriological, and pathological standpoints. Treatment has proved unsatisfactory. The mortality is very high, thus of 111 cases occurring in a recent epidemic in Berlin 76 died, a mortality of 68.5 per cent. Morphine has been freely given to control the pain and sponging with ice cold water has been employed whenever the temperature reached above 102.5° F. Some physicians have claimed beneficial effects from lumbar puncture but experience in this respect has differed greatly.

Dr OSTER concludes that "on the principle of a desperate remedy for a desperate disease the operation seems justified in certain severe cases." The cases now met with, however, are so few that considerable time must elapse before anyone is able to speak with certainty on this therapeutic procedure.

NOSTALGIA

THERE is a melody which boasts of a learned appellation

known by a homophony and far more expressive name in the vernacular, and yet although this binominal disorder is described in the dictionary as "A vehement desire

affecting the physical health," it has not been assigned a place in the Nomenclature of Diseases for which the Royal College of Physicians of London is responsible. The fact too, that home sickness, if imperious to drugs

is nevertheless in the highest degree amenable to treatment, might credibly seem to still further justify its inclusion in the official glossary of the 1058 natural

of the complaint there still remain several

is there any need of either microscope or telescope? Shortly stated the essential factor in the production of nostalgia is an environment differing from that amidst which the affected person passed his or her early days.

When this is the case some intangible influence is generated which reacts upon the victim, but just as happens in many official malades there must first be an appreciable overexposure of soil on the part of the offender.

separate things—race, education, and temperament, but these predisposing causes the last possesses less power than

are more likely to experience home sickness than the
Caribbean Islands, but experience more home sickness
 and tend to respond without sufficient confidence to
 causes and objectives of the program, and tend to

enthusiastic people who continually look forward—will never are, but always to be, blessed—have the advantage, advancing it be, of remaining immune Education rather the want of it, is more potent than temperament, the

trend of civilization, which is equivalent to education, being distinctly in the direction of cosmopolitanism. The deeper the ignorance, the ruder the conditions of life under which a human being exists, the greater the probability of war.

exposed to its influence of his acquiring nostalgia. In Gilbert Islander from Tierra del Fuego, for instance, we

“a cluster of pearls hung upon the equator,” he would
likely bewail his hard lot and pine for his own implement
in hospitable wilderness, and if in like manner a Pac-

with whom to speak, and I was not sure of my own power to do so. I was not sure of my own power to do so. I was not sure of my own power to do so.

But of all the three predisposed races it is which is the strangest: most inconsequential Anglo-Saxons and their Celts, whose manners and customs while abroad

2 less extent probably than people of any other pattern

yet in spite of this they make the best colonists. To
 Celtic Anglo-Saxon the word "Home" is full of the
 most and sweetest meaning, in no other language, it is there
 as much as it corresponds with it in breadth and depth
 of signification. Take the French, *leur* for example how
 wrong in comparison, how unutterably selfish—cen-
 tering the whole interest in the individual, whereas *home*
 implies the importance of others as well. The expression
 of a solitary home "is sometimes used, but the best
 must be either thoughtless or an ignoramus, it not
 with. Such an anomaly as a solitary home is im-
 possible, it becomes a den, it not a prison. "Be it ever
 humble, there's no place like home," and assuredly
 no sin. There is no human being in existence who can
 appreciate the charm of a home more exquisitely than the
 Celtic Anglo-Saxon, and yet he is to be met with in every
 corner of the world. He loves his own native place
 beyond words, but he can endure enforced expatriation with
 giving in to nostalgia. The fact is, he recognises the
 utility of fighting against the odds and so makes his
 mind up to sacrifice a portion of his life or even, if the
 worst come to the worst, the whole of it. He looks upon
 having been denied a home *at home* by fate as a strong
 enough to accept the inevitable with a good grace. For
 nostalgia we must turn to some of the tribe. When all is
 said and they remain in grooves. They may call their failing by
 processes of reason, a purely selfish disorder, whereas love of country can flourish anywhere and takes
 no account of self. And so after all our masters in
 medicine are perfectly right. Nostalgia is righteously
 excluded from a list of the shocks that Anglo-Saxon flesh

POISONING DURING CHLORFORM ADMINISTRATION FROM DECOMPOSITION IN THE PRESENCE OF A FLAME

SEVERAL cases of this serious accident have during the past few years been placed on record. In the *Boston Medical and Surgical Journal* of May 11th Dr K Wilson has added another case to the list. Chloroform was administered to a patient in labour in a small room (12 feet x 13 feet x 8 feet) where three gas flames were burning. In a short time those present felt an irritating sensation in the throat and chest resulting in incessant coughing and gasping for breath which became so violent that the operation—the application of the forceps—could not be proceeded with. The cause of the symptoms was not recognized. An escape of illuminating gas was sought for and all the windows and doors were opened. The operation was concluded undisturbed, not because chloroform was suspected to be the cause of the trouble but because prolonged anaesthesia was necessary. Not long after Dr Wilson noticed the following statement by Emil Aronson. "It is best not to use chloroform by gas light, the free chlorine has not only killed the patient, but in a recent case also the physician, and made two nurses sick for some time." Dr Wilson then investigated the literature of the subject. Professor Zweifel performed a number of laparotomies under chlorine form in a room and in the presence of three gas flames and one ended fatally. The symptoms were intense coughing, dyspnoea, and pain in the wounds from the exertion. Dr Mley of Heme, Wistshaba reported an operation for

3. June 1. 1899, Feb 24th, 1893 p. 617.

gunshot wound of the abdomen lasting four hours, during which the surgeons and nurses were overcome by the decomposition products of the anæsthetic. One nurse died on the second day after the operation. Another case occurred during herniotomy in which three ounces of chloroform were used and half an ounce was spilled accidentally on the floor in a small, badly ventilated room heated by an oil stove and lighted by an oil lamp and a candle. The experiments of Stobwasser are important. He exposed rabbits and guinea-pigs to air laden with the decomposition products of chloroform and found post-mortem evidence of broncho pneumonia and oedema of the lungs. The trachea was deeply congested and both trachea and bronchial tubes were filled with frothy mucus. The literature on this subject is now rather extensive and several very important researches have been undertaken to elucidate the causation of the suffocative symptoms referred to by Dr Wilson. In 1889⁴ Dr D. R. Paterson of Cardiff narrated a case of exactly similar nature to those given above and at his instance Mr Cundall at the University College, Cardiff, examined the fumes given off by chloroform when evaporated in the presence of a flame and found them to consist of carbonyl chloride, a body discovered by Sir Humphry Davy and by him called phosgene gas, as well as of hydrochloric acid fumes. It should be remembered that von Langenbeck pointed out the danger even before Dr Paterson's paper appeared and attributed it to irrespirable carbonyl chloride (chlorkohlenoxyd). The most recent research and by far the most exact is one undertaken by Dr Sebastiano Famulari in the laboratories of the University of Messina. His conclusions are that the fumes which have proved so extremely dangerous and even fatal are those of carbonyl chloride and in this he agrees with Professor Ramsay who has also investigated the phenomena. The obvious practical lesson to be learnt from these cases and the researches is the inadvisability of using the anæsthetic except from a closed inhaler such as Junker's whenever chloroform is required for operations during which a lamp or illuminating gas is employed. Even with the small quantity of chloroform evaporated from the modern forms of Junker's apparatus irritating fumes are given off in small rooms. The inconvenience is notably worse in wet or foggy weather. It is certainly important that this drawback to the use of chloroform should be widely known. Chloroform is a sheet-anchor in midwifery, and unless care be taken and the room in which parturition is to take place be well ventilated and recourse to candles be had, there is always a danger of poisoning by phosgene gas both in the case of the patient and of the medical man.

AN INTERNATIONAL CONGRESS OF WOMEN

As our readers are probably aware, an International Congress of Women is about to be held in London under the presidency of the Countess of Aberdeen. In the section devoted to the professions which are open to women two discussions will be held on medical subjects. On Tuesday, June 27th, in the Council Chamber of Westminster Town Hall, Mrs Garrett Anderson, M.D. Paris, being in the chair, a paper will be read by Dr Sarah Hackett Stevenson from the United States on the Training and Qualifications of Women Doctors, and in the subsequent discussion Dr Poznansky Garfield of Russia, Dr Tiburtius of Germany, and Dr Aletta Jacob of Holland will take part. A paper on Women's Work as Doctors in Hospitals, in Private Practice, and under Government will be read by Dr Stefanofskaja Kosekevitch of Russia and Mrs Scharlieb, M.D. Lond., of London, and Dr Ellen Sanderlin of Sweden will speak on the subject. On Friday, June 30th, papers will be read on subjects connected

with nursing, Mrs Neill of New Zealand contributing a paper on the Professional Training or Status of Nurses. Mrs Quintard of the United States will read a paper on Naval and Military Nursing, Mrs Hampton Robb will speak on the Organisation of Trained Nurses' Alumnae Associations and Miss Scovell on Nursing Organisations. Many of the papers which are to be read in other sections are of great medical interest and although the direct benefit from congresses of all kinds is apt to be overestimated yet we shall look forward to much good resulting from the discussion of the numerous difficult problems which so vitally concern the well being of half the human race. We may mention that the tickets of membership of the Congress, price 7s. 6d. can be obtained from Miss Teresa Wilson, honorary secretary to the International Council of Women, 36, Victoria street S.W.

RECURRING TYPHOID FEVER AT CHICHESTER

THE city of Chichester, where typhoid fever seems to have made itself an all but permanent home, is once more the seat of an outbreak of this disease and rumours are current that this recurring malady is due to one and another cause, including the consumption of shell fish—such as cockles—which have had opportunity of becoming contaminated. We are unable to learn that the town council are taking any such steps as they should adopt with a view to ascertain what the real cause or causes of this outbreak are, and yet there are few places in this country where more assistance has been rendered to a local authority by way of indicating the line of investigation that should be adopted than is the case with Chichester, which has been visited again and again by inspectors of the central authority. It might have been thought that the stigma of the recurrence of a preventable disease such as typhoid fever which attaches to Chichester would in itself have led the town council, as the local sanitary authority, to organise a definite scheme for a complete etiological inquiry into every case of this disease as it arose, but nothing beyond the rumours and differences of opinion seem to be available and in the meantime the disease continues its periodic recrudescences.

'THE ROADS IMPROVEMENT ASSOCIATION' INCORPORATED

AN association has been incorporated bearing this title and it may interest our readers to know that they can become members on payment of 5s. per annum or two guineas for the life membership. Such payments can be made to the honorary secretary and treasurer, Mr Dudley Warburton Lonsdale Chambers, 27, Chancery lane, London, W.C. The objects of the association are as follows—

- (1) To circulate amongst ratepayers, county councillors, members of boards of works, road surveyors, and others having control of, or employed in connexion with, roads information upon all matters concerning the construction, maintenance, and repair of roads, and to issue such papers, books, and other literary undertakings as may seem conducive to these objects;
 - (2) To confer with councils and vestries, gas, water, and electric companies and other public bodies in regard to all matters affecting the construction, maintaining, breaking open, observing, watering, and repair of roads;
 - (3) To promote improvements in the laws regulating roads;
 - (4) To engage and pay for professional advice, remonstrate with authorities who allow roads to suffer from want of repair or neglect, and if necessary take legal action to enforce the rights of the public and ratepayers;
 - (5) To oppose and resist any proceedings calculated to deprive the public of any rights over such roads.
- In addition to road maintenance the association also takes up the question of finger posts and milestones, without which no road can be considered perfect. Medical men as members of the public are interested in the maintenance of good roads, for good roads are cheaper than bad ones as well as being vastly pleasanter to travel upon.

⁴ THE LANCET March 12th, 1888, p. 749.
⁵ THE PRACTITIONER vol. xiii. 1889, p. 418.

THE PROFESSOR OF PHYSIOLOGY IN EDINBURGH
UNIVERSITY

that in two obvious directions the condition of roads is of particular importance to our profession. First, a badly made and badly kept road is one which knows no medium between the conditions of stony swamp and sandy desert, and roads which are perniciously damp or too dry for filthy dust are sources of no small aggregation of many pathological conditions. Secondly, and in a more exclusive way, the condition of the highways concerns the medical practitioner nearly, for whether he makes his rounds in dog cart or on bicycle, his work is immeasurably lightened to him if the roads by which he has to travel by all lights and in all weathers are good and properly maintained.

THE SUPPLY OF GLYCERINATED CALF-LYMPH

[illegible]

CARDIFF INFIRMARY

RECORDED cases of this parasite are very few, and consequently the paper which we publish by Dr A J Chalmers, Assistant colonial surgeon at the Gold Coast Colony, is of exceptional interest. The parasite was termed "pentastoma contracta" by von Siebold in 1852, "hungerfische constrieta" by Krichenmeister and R Blanchard (1888), and "nematoideum hominis" by F runner and Miesing. Dr Chalmers states that nothing is known at present as to its history or as to the means by which it enters the body, but he believes that it enters by some means into the alimentary canal or that from there it proceeds to the liver, the cysts in which appear to be dilated biliary ducts, and cysts in the peritoneum. According to other authors, however, the parasite is only known in the larval condition. It has been found in negroes and curiously enough in the gharials in which form Dr Chalmers considers it to exist he does not say but states that he intends to describe its anatomy at another time. The account of the necropsy on his patient is certainly interesting. Numbers of parasites were observed moving freely in the abdominal cavity over the surfaces of the various organs and others were found coiled up in the cysts contained in the liver. Similar cysts were found in the liver and in each a parasite was found. Dr Chalmers' clinical comments are also interesting. He thinks that the only possible means of diagnosis during life would be the presence of the parasites in the faeces in cases of washing and immersion in negroes, but the disease appears to last some time before causing the death of the patient.

Accidents are, of course, unavoidable, but they should be reduced to a minimum and should always be on the safe side—that is, it is better that the vaccine should be slightly deteriorated rather than that undesirable micro-organisms should be present, but the conditions of preparation are now so well understood that even the accident of insignificant activity of the lymph should seldom occur. We make those remarks both in the interests of the public and of those who provide glycerinated lymph, as it is absolutely necessary that continual watchfulness and care should be exerted in order that any falling off in the quality of the lymph supply may be avoided. If still and care were not required anyone could supply vaccine lymph, but as skill and care are required those who are interested in the production of this material should make every effort to carry on the work which they have undertaken properly and efficiently. We understand, by the way, that Dr Copeman has quite recently devised a method of getting rid of the glycerine when it has done its work, thus avoiding its continued action on the specific microbe. The details will soon be made public.

PENTASTOMA CONSTRICTUM

RECORDED cases of this parasite are very few, and consequently the paper which we publish by Dr A J Chalmers, Assistant colonial surgeon at the Gold Coast Colony, is of exceptional interest. The parasite was termed, "pentastoma contracta" by von Siebold in 1852, "hirsutula contracta" by Krichewmeister and R Blanchard (1888), and "hematodum hominis" by F runner and Miesing. Dr Chalmers states that nothing is known at present as to its history or as to the means by which it enters the body, but he believes that it enters by some means into the alimentary canal or that from there it proceeds to the liver, the cysts in which appear to be dilated biliary ducts, and cysts in the peritoneum. According to other authors, however, the parasite is only known in the larval condition. It has been found in negroes and curiously enough in the gharials in which form Dr Chalmers considers it to exist he does not say but states that he intends to describe its anatomy at another time. The account of the necropsy on his patient is certainly interesting. Numbers of parasites were observed moving freely in the abdominal cavity over the surfaces of the various organs and others were found coiled up in the cysts contained in the liver. Similar cysts were found in the the liver and in each a parasite was found. Dr Chalmers' clinical comments are also interesting. He thinks that the only possible means of diagnosis during life would be the presence of the parasites in the faeces in cases of washing and emaciation in negroes, but the disease appears to last some time before causing the death of the patient.

yearly are realised. It is very apparent that unless an alteration is made on one or the other side of the ledger each year will find the governing body in a worse plight than the last. In a town of the size and importance of Cardiff—the self-styled Welsh metropolis—there should be very little difficulty in raising considerably more than the amount required to keep the full number of beds in constant use and it is any thing but creditable to the townspeople that any curtailment should even be suggested. Instead of decreasing the number of beds available they should rather be added to, for even 180 are none too many for the district served, including as it does not only Cardiff borough, but Pontypridd and the Rhondda valleys with the intervening townships—an aggregate population of over 400,000 persons.

"THE PRE-PERFORATIVE STAGE OF TYPHOID ULCERATION." CLOSURE OF A PERFORATION BY ADHERENT OMENTUM

THE following case, published in the *Boston Medical and Surgical Journal* by Dr D J M Miller, is interesting as an example of a rare event—recovery from typhoid perforation of the intestine—and in the manner in which this result was brought about. The patient was a girl, aged 11 years, and the disease ran a rather severe course. On the twenty-third day there were four hæmorrhages from the bowels (about 24 ounces of blood were lost), increased tympanites, abdominal pain and tenderness on deep pressure, and slight rigidity of the recti muscles. These symptoms abated, but not entirely, until the twenty-sixth day, when the patient complained much of abdominal pain. The abdomen was moderately distended and slightly rigid, on deep pressure there was considerable pain which was not localised. At 10 A.M. the temperature had fallen from 103.2° F at 7 A.M. to 99.4°. At 1 P.M. the temperature rose to 101.4°. On the next day the tympanites was marked, the lower border of liver dullness was in the nipple line one and a half inches above the costal margin. Pain was continuous and tenderness was great, especially above the umbilicus, there was considerable muscular rigidity. The temperature was 102.8°, the pulse was 140, and the respirations were 32. Operation was decided on should the condition not speedily improve. On the following morning the child was better, the temperature was 99.6°, the pulse was 95, distension and tenderness were much diminished, and pain was absent. Convalescence proceeded. On the thirty-fifth day a relapse, more severe than the first attack, began. On the thirty-ninth day (the fifth day of the relapse) seven ounces of blood were passed. Seven days later dull and continuous abdominal pain was again complained of. On the next day the tympanites was increased, but the liver dullness was unchanged. Tenderness was very marked, especially at a point just below and to the left of the umbilicus. There was decided muscular rigidity. Vomiting occurred once. The temperature was 103°, the pulse was 134, and the respirations were 56. It was thought that perforation if not present was imminent. At 4 P.M., three hours later, the temperature had fallen to 99.8°, it rose rapidly to 103.4° at 7 P.M. Symptoms of perforation and peritonitis—collapse, vomiting and great tympanites and rigidity—rapidly developed. Death occurred on the next day at 1 P.M. At the necropsy considerable gas and fluid were found in the abdominal cavity. There were much lymph and many recent adhesions. The great omentum was attached to the ileum, serving to close a small aperture in an ulcerated Peyer's patch which had evidently perforated some time before. Another perforation was found which permitted the escape of the intestinal contents. A similar case has been reported by Buhl. A patient died from hæmorrhage

on the twenty-third day after symptoms of perforation. A piece of omentum was found adherent to and completely closing the opening. Cushing has emphasised the frequency of what he terms a "pre perforative stage of ulceration," which he describes as "a localised inflammation of the serosa leading to a slight adhesive peritonitis due to the near approach of an ulcer to the general peritoneal surface." The symptoms, according to Dr Miller, are a gradual rather than sudden onset of continuous pain which is complained of by the patient himself, associated with more or less general or localised abdominal tenderness and often with slight muscular rigidity. Cushing states that there may be moderate leucocytosis. Vomiting and change of temperature are usually absent. The case described corroborates Cushing's views. There was almost continuous complaint of pain with tenderness on deep pressure and variable but slight rigidity for three days preceding the first perforation and for one and a half days preceding the second. Dr Miller remarks that if there is a definite recognisable pre perforative stage operations undertaken then will be more successful than later. But it seems to us that those operations would often be unnecessary quite independently of erroneous diagnoses which would be still more likely to be made than in cases with actual symptoms of perforation. More value is to be attached to his suggestion that the recognition of this stage would put the practitioner on the alert to enjoin greater quietness and the cessation of bathing, and make him watchful for more pronounced symptoms.

"HAY-CORYZA"

THE Professor of Oto rhinology in the University of Turin, Dr Giuseppe Gradenigo, drew attention at a late meeting of the local Academy of Medicine to the increase of hay fever, or, as he prefers to call it, "corizza da fieno"—an increase observable mainly among the well to do classes of Italy. The same phenomenon has also been noted and commented on by French physicians among the corresponding class of their compatriots. This fact would seem to point to hyperalimentation (or "gout") as a concurrent cause of the malady—if not as its *causa causans*. Be that as it may, Professor Gradenigo would define the coryza in question as "a sub-species of the spasmodic, vaso motor coryza which recognise two main etiological factors—an irritating agent in the interior of the nose (polypi, 'creste del setto'—excrescences of the septum—and such like) or an agent imported from without (the pollen of certain flowering plants, the dust or detritus of great thoroughfares) coincident with an enhanced susceptibility of the nasal mucosa." The symptoms of the coryza he would classify in the following sequence: fits of sneezing, hyper secretion of serum, turgidity and congestion of the nasal mucosa, sometimes of the conjunctivæ and of the tracheal and bronchial mucosa. Passing in review the various remedies in more or less acceptance he finds none of them really efficacious and would counsel "allontanamento" (estrangement) from the irritating agent, bland lotions of the nasal passages "con soluzione fisiologica," alternating with the use of inert fatty substances (these latter of themselves sometimes proving effective), while he would prohibit cauterisations of the mucosa or the repeated use of cocaine. The President of the Academy (Dr Edoardo Perroncito, Professor of Parasitology in the University) asked Professor Gradenigo "if, in the exudations of the rhinitis in question he had found the corpuscles of the pollen of plants used for feeding cattle (*piante foraggere*)". "No positive researches in this direction had yet been made," was the reply, "but, till then, the subject cannot

was able to obtain more exact indications. In 1879 he was employed as medical officer in charge of an English vessel called the *Ilion* (sic) which had been chartered by the French Government for the purpose of conveying coolies from Pondicherry to Martinique. On the voyage, which lasted four months, beri beri showed itself in one group alone out of the many into which the human cargo was divided. The contaminated section consisted of Malagascans exclusively. Fearing lest they should become debilitated by bad food and cook it for themselves in a special part of the ship. Their meals were simple, so far as quantity was concerned, consisting of rice, salt fish, dried vegetables, and kid flesh, yet they suffered severely. The remainder of the coolies consumed grease in one form or another and remained perfectly free from beri beri throughout the voyage, but Dr Brémond is by no means sure that he has found the cause of the disease. Beri beri is probably a specific affection, the deprivation of fatty matters in the food merely producing a condition of body favourable to the development of its active agent should such exist.

THE LIVERPOOL SCHOOL OF TROPICAL DISEASES RESEARCH EXPEDITION TO WEST AFRICA

THE Liverpool School of Tropical Diseases which was formally opened by Lord Lister on April 22nd, 1899, has steadily progressed since its inauguration. The special ward at the Royal Southern Hospital set apart for the clinical instruction of the school has been full to overflowing ever since with typical cases of malaria and other tropical diseases. The School lately made an offer, which has been accepted, to receive from the Colonial Nursing Association, London, three nurses intended for service in the tropics and to give them a special training at the expense of the Liverpool School. The committee have for some time had under their consideration the question of organising and despatching to the West Coast of Africa a special expedition for the purpose of investigating the causes of malaria and other indigenous diseases. They have now definitely decided to send out such an expedition and the arrangements which are being made for the purpose will be found in the communication from our Special Correspondent at Liverpool.

THE next examination for the Charles Murchison Scholarship in Clinical Medicine, which is open to any student of medical studies in attendance at recognised classes or hospitals in Edinburgh or London, will be held in the University of Edinburgh on Friday and Saturday July 7th and 8th, 1899. The scholarship is of the value of 20 guineas and is tenable for one year. Intending candidates are required to send in their names, with evidence of their qualification to compete, to Dr Thomas R Fraser, Dean of the Faculty of Medicine, University New Buildings, Edinburgh, not later than July 1st.

THE next dinner of the Glasgow University Club in London will be held at the Grosvenor Restaurant on Friday, June 30th, at 7 o'clock P.M. Lord Kelvin has promised to preside and the special guest of the evening will be Sir William Gairdner, K.C.B. M.D. Edin. The honorary secretaries of the dinner are Dr Norman Macleod, 13, Queen Anne-street, W., and Mr James M. Dodds Dover House, Whitehall, S.W., to whom application should be made by those wishing to attend.

THE annual general meeting of the Brussels Medical Graduates' Association will take place at the Café Royal,

STRAWBERRIES AND GOUT

A WRITER in *Nature* speaks of the cruel medical tyranny which banishes the strawberry from the diet of the gouty and notes what Linnæus had to say about the curative properties of this delightful fruit. "This great naturalist was persuaded to take strawberries during a severe attack of sciatica with the result that a sweet sleep ensued and when he awoke the pain had sensibly subsided. On the next day he ate as many strawberries as possible and on the following morning the pain was gone and he was able to leave his bed. Gouty pains returned at the same date in the next year, but they were dispersed as soon as Linnæus was able to get strawberries. Although strawberries are forbidden to the gouty by some authorities, by others they are permitted, the fruit being regarded as a useful food for gouty persons on account of its richness in the salts of potash, soda, and lime and its cooling diuretic, and laxative qualities. The analysis of the straw-berry shows it to be particularly rich in soda salts and in spite of the high percentage of water this fruit excels all other common fruit in the amount of mineral salts. The chemistry of the strawberry therefore would teach that this fruit is likely to be beneficial in gouty states.

THE ETIOLOGY OF BERI-BERI

WITH reference to an article on the preventive treatment of beri beri by Dr Laurent of the French navy which appeared in the *Archives de Médecine Navale* for March last and to which we referred in an annotation, Dr P. Brémond, who was quoted by Dr Laurent, writes to our French contemporary to say that when he was lecturing on the subject in 1885 his views regarding the prophylactic virtues of fatty food in beri beri were by no means "purely theoretical," being, on the contrary, based upon two remarkable facts which had come to his knowledge while on foreign service in 1877-79. Of these the first was as follows: "The penitentiary on the island of Pulo Condore, containing upwards of 1000 prisoners, was at that time regarded as a kind of sanatorium, the air—as Dr Brémond's predecessor observed—being a veritable prophylactic against beri beri. Under an unusually intelligent commandant the convicts were employed in various industrial pursuits, as far as possible in the open air, and were also encouraged to keep pigs and poultry and to cultivate private gardens. Their diet, too, was carefully supervised, and altogether they were treated more like colonists than convicts. This condition of things went on for several years when unfortunately the intelligent commandant was replaced by an official of ordinary calibre under whom Pulo Condore soon lost its Arcadian character. The out of door life came to an end and the prisoners rigidly confined within four walls, found themselves condemned to an existence of complete inaction. Their food also underwent a change for the worse, consisting for the most part of water cooked rice and a little salt. Under these unhygienic circumstances beri beri promptly made its appearance, exacting victims by the hundred. An inquiry soon brought about an alteration of diet with pork as the staple ingredient, and like a charm the epidemic was stayed. In this case, although the food was clearly at fault, there was nothing to point to the particular item the absence of which was responsible for producing the disease, but in his second experience Dr Brémond

Regent-street, W., on Wednesday, July 5th, at 6 30 P.M. At 7 15 for 7 30 the members and their friends will dine together. Brussels medical graduates wishing to be present at the dinner are requested to communicate with the honorary secretary, Dr Major Greenwood, 243, Hackney road, N.E.

THE new buildings which have recently been completed at the London Hospital Medical College will be opened on July 18th by Lord Knutsford. The opening ceremony will be followed by the distribution of prizes to the students and nursing probationers in the Library of the Medical College by Lord and Lady Knutsford.

ON the occasion of the distribution of prizes to the successful students at Guy's Hospital by Mr Robert Gordon, on Friday, July 7th, a garden party will be given by the governors and staff, and the new laboratories, wards, and museums of the hospital will be open for the inspection of the guests.

SIR HENRY THOMPSON, Bart., has been nominated an Honorary President of the Thirteenth International Congress of Medicine to be held in Paris in August, 1900.

THE PROPOSED REGISTRATION OF MIDWIVES

ON June 15th, at the West Ham Hospital, Stratford, E., in reply to the resolution—

That the Wood Green and District Medical Society and the East Suburban Medical Protection and Midwifery Society Limited view with regret the fact that Mr Victor Horsley has ceased to carry on his opposition to the recognition at law of partially qualified practitioners in that he is at present supporting a Bill giving a legal status to midwives and trust that he will reconsider his position—

Mr VICTOR HORSLEY said It is with the greatest pleasure that I come here this afternoon to enter into this discussion on such an extremely important subject. Mr R. F. Tomlin in his remarks has divided the matter into two heads—(1) the question of the registration of midwives as midwives, and (2) the question of the giving of certificates by such bodies as the Spectacle-makers' Company and opticians. At first I understood the resolution passed by you at your respective general meetings to refer to the Bill at present before the House of Commons which is put forward by the supporters of the Midwives Institute and is backed by a certain number of influential Members of Parliament. If you passed your resolution under the impression that I was giving my support to the Bill now before the House you have been placed in a false position, I am as much opposed to that Bill as any of us, and under those circumstances I wrote to the secretary of the Wood Green District Medical Society to say so. If, however, the Bill which was referred to in Mr Tomlin's resolution is the Bill which has been furnished by the British Medical Association I think then that the resolution of your society distinctly applies to me, and I shall therefore assume that the only Bill referred to is that of the British Medical Association. What, then, is the position of affairs and what is my position towards you as your Direct Representative? The position of affairs is this. Years ago a Bill was framed by the British Medical Association for the purpose of registering midwives to secure that they should be properly educated in the carrying out of their work. Of course, midwives have always existed and with midwives as such no one has ever attempted to interfere, but circumstances arose which made it necessary for their being put on a list for the purpose of controlling their practice, so we see that what there is of novelty in this question has arisen with the earliest attempts made by the British Medical Association years ago to control the practice of these women and not to give them practice. I repeat the idea of this Bill was to control their practice and not as has often been assumed by many, to confer anything in the way of additional practice upon them. That Bill dropped and for some years nothing further was heard of the matter. Then arose a kind of nurses' club—also called the Midwives' Institute—and the

members of this club took upon themselves to raise the matter up afresh by introducing a Bill into the House brought forward by Lord Balfour of Burleigh and then began the acute phase of the question, since that Bill of Lord Balfour's was a far more objectionable one in many ways than the Bill now brought forward in the House of Commons by Mr J. Balfour. The matter was further advanced—long before I became your Direct Representative—by the General Medical Council who practically accepted Lord Balfour's Bill with the introduction of a few verbal corrections. We need concern ourselves, however, no more with that Bill—it dropped and was replaced by that of Mr Egerton of Tatton, which was practically the outcome of the committee of the House, which reported in favour of some kind of registration being adopted by the Government. This Bill has also disappeared and we are now face to face with Mr J. Balfour's. Mr Egerton's was before the General Medical Council when I stood in 1897 for your suffrages, and reference has been made by Mr R. F. Tomlin to a letter which I wrote to Mr Jackson and the substance of which I maintain now as then. I strongly object to the giving of a legal status to persons to practise midwifery, but I think that when this resolution was laid before you those who are interested in this subject forgot a document which I had circulated before being elected and when I was a candidate I should like to read that document to you, though you have all had it before, but it probably shared long since the fate of all circulars and such documents.

THE GENERAL MEDICAL COUNCIL.

DYE ELECTION 1897

To the Registered Practitioners of England and Wales

LADIES AND GENTLEMEN.—As I find that considerable misconception and confusion prevails concerning the so-called "midwives question" I beg to lay before you the following facts:—

1. Persons called midwives are at the present time and in considerable number carrying on midwifery nursing, and irregular midwifery practice.

2. In recent years but especially since 1889 when Sir Walter Foster brought forward and carried in the General Medical Council a motion urging the Government to construct and pass a law for the registration of midwives a popular agitation has been carried on to effect this and to confer upon them what is practically a professional title and status.

3. There is also a widespread and obviously just feeling that the calamities which are caused at present by ignorant midwives cannot be allowed to continue and the registration of the title midwife or midwifery nurse has been erroneously supposed by the General Medical Council to safeguard the interests of the public.

4. To procure safety for the public it is clear that the so-called midwives must be taught midwifery nursing and that any person who follows the calling of a midwifery nurse without having had such teaching must be punished by statute.

5. No legislative guarantee of this kind however is possible unless the names of properly taught midwifery nurses are placed on a list or register.

6. To meet the requirements of the public as laid down in the report of the Select Committee of the House of Commons, 1893, it is evident that the Privy Council will at no very distant date introduce a Bill which to judge from the two (Lord Balfour's and Mr Egerton's) already sent to the General Medical Council for consideration and report "as soon as possible" (*vide Minutes G. M. C. 1897*) will probably contain no safeguard either to the medical profession or the public.

7. The case of the medical profession has been gravely prejudiced by the practical adoption by a committee of the General Medical Council (of which Sir Walter Foster was a member) and subsequently by the Council of the former of these Bills and by its amendment in various unimportant particulars without provision of a single safeguard against the establishment and quasi legislation of a body of unqualified practitioners in midwifery such as the existing midwives.

8. The General Medical Council has now appointed a committee to consider Mr Egerton's Bill the question is therefore practically reopened.

9. The Parliamentary Bills Committee of the British Medical Association, through a sub-committee of which I was chairman has prepared a Bill for the teaching and regulation of obstetric nurses which is now before the Council of the Association for consideration.

10. The point of immediate importance to the profession in this question at the present time is the strict preservation of the triple qualification in medicine, surgery and midwifery alone possessed by registered medical practitioners.

11. There are two methods of securing this of which the first is the proposition by the Lancashire and Cheshire Branch of the British Medical Association—namely. That every case of midwifery attended by a midwife should be seen by a registered medical practitioner within 24 hours of the commencement of labour. This I believe would adequately meet the case.

12. The second however is more fundamental in principle and is what I should endeavour to secure acceptance by the General Medical Council and reference to the Privy Council as being a complete legislative safeguard against the attempted contrivance of the Medical Acts. I propose that when any report on a Midwifery Nurses Bill is brought forward for final adoption there shall be first adopted a Bill for the amendment of the Medical Acts to prevent the practice for gain of medicine, surgery and midwifery by any but practitioners registered under the Medical Acts.

13. This safeguard will at the same time put a stop to the irregular practice in diseases of women and children carried on at the present time by midwives certificated or otherwise, and chemists.

I am, yours faithfully

VICTOR HORSLEY

You all had this document. Some of you may have voted
 for me, some against me, but at any rate you knew perfectly
 what is normal or abnormal labour

You have the law entirely in your own hand, but you will not exercise it. You have the right to choose men who shall go to that Council and it is your business to see that such men do go. I may say at once in passing that I understand that the Medical Acts Amendment Bill which the Parliamentary Bills Committee framed and sent up to the Council has met with bad fortune. The first point in it was the insistence that the representation of the corporate bodies on the General Medical Council should be a true electoral one. That Bill has been emasculated by the council of the British Medical Association. I therefore do not approve of its views any more than does Mr Tomlin. All I have to say is this, What policy are we going to adopt in connexion with the matter? Mr Tomlin says, oppose the Bill *in toto* tooth and nail and it will never pass. From my point of view it is impossible to stop the Government when they are interested in a matter from forcing a Bill through the House, and if they are bent on such a thing the only thing to do is to secure as far as possible that that Bill shall be modified in accordance with the wishes of the profession. My conversation with Members in the House has shown me that Members only care for votes, that the medical profession only form a small fragment of the community and are easily out voted by the mass of the electorate. The Members of the House do not care what we say to them respecting any interference with their future re-election. The second point is, How are you going to raise popular opposition to this Bill? What has been the effect in the past? The only effect on the Government that has ever been brought about was obtained through one or two bodies, such as the British Medical Association or the General Medical Council. Put the General Medical Council out of court at once, for they have done what they think fit. You can only do it through the British Medical Association Council or through motions passed in the branches of the Association. You have already settled this matter by your branch. Your branch three years ago sent up answers on this subject and surrendered their responsibility in the matter. The Council have crystallised those answers in the form of the Bill before you. How, therefore, can you move the Association to take up any other attitude on this question? Mr Tomlin thinks it is possible, I do not. Dead opposition to all legislation is an impossibility—it is a policy that will not work, and under those circumstances I think this proposition of dead opposition is absurd. The chairman, Dr F J Smith, has placed in my hands a letter from Dr Glover in which he says that he thinks modification of the Bill a more practicable policy than one of blank opposition to all legislation. I have spoken entirely for myself in this matter. Now comes the question, What have I done in regard to these Bills? I have endeavoured to obstruct all Bills which contain fundamental errors, so far we have succeeded in postponing Bill after Bill until we have got Mr Balfour's Bill in its latest form will include safeguards in the interests of the public and of the profession provided they are not dropped out as the Bill goes through the House. The position of the Government is evident, as anybody can see who reads the minutes of the General Medical Council. The President of the Privy Council only wants to get a measure which shall be a kind of compromise between the promoters of Mr Balfour's Bill and the profession and to put that before the House as a Bill. Everything goes to prove this and that the Government intend to bring in a Bill which, if they choose to back, they can force through irrespective of our wishes in the matter. Therefore, the proper thing to be done now in this question is to press the British Medical Association Council to urge upon the Government the adoption of their Bill which does include everything we want, on the assumption that some legislation will be carried out and that that legislation ought to be modified to our requirements—that is the position I advocate at present, gentlemen, and it seems to me to be a perfectly practicable one.

I now come to the question of certificates of spectacle-makers and obstetrical societies. In spite of statements by Mr Carter this question is a new one—new in this sense that we have a medical practitioner capable of holding an examination of a character which though it may only deal with refraction is undoubtedly a professional examination. On that point you have your answer from the General Medical Council, it was that they are ready to consider such conduct of a medical practitioner as possibly coming within the scope of Section 29 of the Act, but they cannot take up the matter themselves and they leave it to you to take action. As far as

you are concerned with the question of certificates in general all of them are poisonous and none perhaps more so than the London Obstetrical Society. What is the position of the Council in this matter? It is one of complete stultification. The Council first declared that the original London Obstetrical Society diploma was a document which ought not to be issued by any practitioner under pain of his conduct being considered infamous. The late President, Sir Richard Quain, held communication with the London Obstetrical Society who altered the wording of their diploma slightly, and the General Medical Council accepted it. The memorial recently presented to the General Medical Council, if shorter and couched in more business like language, would have obtained more support. The matter was brought up again to the Council on the Executive Committee and Mr Brown and I urged that a special committee should consider the facts raised by the memorials. Again we were out-voted by the usual phalanx of reactionaries led by Mr Carter. We shall bring the matter up again, but of course as the Council does practically no work between the sessions six months is lost. Finally, with respect to the safeguards I consider necessary to all midwifery legislation, the most important, as I said in 1897 when candidate for your votes, is the Amendment of the Medical Acts. To secure this I intended to make a resolution at the General Medical Council but was glad to find that Dr Glover had already put on the programme a notice of motion to appoint a committee to draft proposals for such a Bill. This motion was out-voted by Mr Carter and his friends, but we now have them on the horns of a really picturesque dilemma. Some years ago they declined to listen to the British Medical Association. It was, to speak in the sense of Dr MacAllister's words, an outside with which the General Medical Council had little concern. Now last week the same opponents reasoned that it was better that an outside body should do the work. We must therefore see that the British Medical Association actively pushes forward this most fundamental reform.

THE ROYAL SOCIETY (SECOND) ANNUAL CONVERSAZIONE

As is invariably the rule the second annual conversazione of the Royal Society—an event generally known as "Ladies' night"—proved much more attractive from the point of view of display than the previous event in May. Indeed, the exhibition held last Wednesday (June 21st) comprised the same subjects of demonstration as before, but with some interesting and pretty additions which served to relieve the *tout ensemble* from that severity of aspect which characterised the first display.

Electricity appeared to be the favourite subject. In this connexion, appropriately enough, there was a lady exhibitor in the person of Mrs. Ayrton who presented to view a very attractive series of experiments illustrating the hissing of the electric arc. This noise appears to be due to the burning of the carbon in contact with air instead of volatilising. On account of an increase in current the carbon vapour no longer protects the carbon pole and so it commences to burn with characteristic sound. In the absence of air, as in a vacuum, hissing is not produced nor is it when the poles are surrounded by an inert gas. On the other hand, when oxygen is directed upon the arc light hissing is soon established even with a small current. Mr Mackenzie Davidson showed a very ingenious apparatus enabling the Roentgen ray shadows upon a fluorescent screen to be seen in stereoscopic relief. By this apparatus a foreign body may be very correctly and quickly located. The new interrupter known as the Wehnelt interrupter has been improved and some remarkable effects produced by this apparatus were shown by Mr Swan, F.R.S., and Mr A A Campbell Swinton. Mr Shenstone was busy in showing the making of tubes from rock crystal in the oxyhydrogen blowpipe flame. Glass made in this way promises to become of great value for experimental purposes since it is electrical and permeable by the x rays. Mr Boys, F.R.S. interested the visitors with a very simple apparatus producing a diffraction colour photograph. This photograph is made by successively printing on an albumen plate three photographs which had been taken through red, green, and

blue glasses respectively, and upon the plate also ap-
painted "resting railways" of pictures corresponding to the
wave length of these colours. The result is very beautiful,
the most striking subject shown being a large stained
glass east window. This demonstration was undertaken
for Mr Wood of the University of Wisconsin. Mr Saville
Kent, F.R.S., exhibited a beautiful collection of natural
colour photographs of zoological and botanical subjects. Mr
J. B. DeLaurel proposes to re-establish platinum as a standard
of light. The apparatus was in full working order,
just as it is about to solidify. The chief exhibitions
on the table in the middle of the principal library
were microscopic specimens. Among these Dr Patrick
Manson's exhibit showing the development of the
malerial parasite collected considerable interest. Close
by was an admirable collection of mosquitoes recently
received at the Natural History Museum for study in
reference to the connection with mosquitoes. This
exhibit was presided over by Professor Hay Langsdorff, F.R.S.
Much of the space on the same table was devoted to the
exhibition of cultures and microscopic specimens of certain
pathogenic bacteria by Dr MacLachlan for the Jenner Institute
at Comber, however, was assigned to
Dr Gladstone who showed some interesting ancient metals
from Egypt, Babylon, and Britain. Amongst these was
powdered galena from Glashbury which was used for
blackening eyebrows. There were many other objects of
interest which have already been described in a previous
article in THE LANCET of May 6th, 1899 on the occasion of
the first conversations.

THE ARTICLE CLUB INDUSTRIAL EXHIBITION

On Saturday afternoon, June 17th, the members of the
Article Club held an exhibition in the south nave of the
Crystal Palace. The Article Club is a club composed of
commercial men, whose object is to form a combination of
the world's foremost industries—a somewhat ambitious pro-
gramme, by the way, but one which the promoters take
such of the exhibits as were of interest to medical men, but
speaking generally we may say that the club managed to
get together a very interesting and representative commercial
show.

Messrs J and J Colman, Ltd, at their stall, distin-
guished by a model of Carron Works, their factory
at Norwich, showed some new shrimps consisting of
mustard spread on a light pliable fabric consisting of
two canvases. Their concentrated mustard oil a greenish
opaque product expressed from the seeds, is of a specially
refined character. Messrs W J Bush and Co, Ltd, of
Artery Lane, London, had a good show of essential oils and
essences of all sorts. Messrs Bassett and Johnson, of 31 and
32, Snow Hill, E.C., showed their mustard plasters on paper
and cloth, which must be dipped in tepid water, it water of a
higher temperature is used the ferment myrosin, which acts
upon the glucosides producing the volatile oils, is coagulated
and so rendered incapable of entering into reaction
with the cancles in different sizes, to which reference has
already been made in our columns, were shown, they are
much used for distillation of rooms by sulphurous acid gas
Their bellows plasters, containing the pharmacopoeial
alcohol strength (0.5 per cent.), are excellently pro-
fected by linen on each side. Mention may also be made
of their aseptic ligatures carboided gauze and cotton and
rubber adhesive plaster (Meads). Mr W S Stanley, of
13, Pallway approach, London Bridge, S.E., exhibited a look-
ing of optical instruments of delicate workmanship, and on view
were the public cutting and working and frame making for
the spectacles performed by skilled workmen. Mr Stanley

also showed some glasses with rigid frame (so as not
to fold) which at the nose by light spring plaques
applying themselves "with soft pressure. The indur-
ated rubber goods of Messrs J E Hopkinson and Co,
Ltd, of West Drayton, Middlesex, were well worth
inspection. The Thornton Scarth Syndicate, Ltd, of Br-
imingham, represented the Acetylene Lighting Industry.
They Small box Hospital (near Coventry) is lighted by this
gas. We were informed by the firm that they are about to
put on the market a portable apparatus for laryngoscopic
work which may be carried in the waistcoat pocket. Mellin's
Food, Limited, had a prettily arranged stall of their
of the exhibit of the Boveri Co, of
30 Harrington street, E.C., contained a great variety
of preparations, including eskimados, Malto-Carni, meat
juice, marrow, and trol, which we have already noticed.
At the stall of Dr Jaeger's Sanitary Woolen System
ham Circular frame was in motion, illustrating the
of 95 Milton street, London, E.C., the Nottingham-
rearing of pure undyed woolen material for the
Jaeger underwear. A very fine woolen material "taste"
seems specially well adapted for summer wear and for
the colonies. Messrs Defties and Sons, of 147, Hounds-
ditch, London, E.C., showed the Pasture Filter and
division disinfection appliances. The Saturated Steam Dis-
infecting temperature obtained in each operation and its
prominent feature in the exhibit is Nettle Hospital, E.C., was a
Chambers, and Co, Ltd, of 331, Gray's Inn road, W.C.,
exhibited numerous preparations of the non poisonous dis-
infectant "Izal"—emulsion, soap, ointment, tooth powder,
Izal. The value of Izal was pointed out in a paper in
THE LANCET of July 1st, 1893. Izal lint and gauze were
also shown and preparations of Izal oil called perles, used
for intestinal antiseptics.

Other stalls of interest were those of the Patent Boreax Co,
of 129, Holborn, Messrs Hall Matthews and Co, sanitary
engineers, of 88, Wigmore street, W, and Messrs B and A
Glasgow. At the stall of the Messrs Siemens, of Kilmnigh Park,
Glasgow, was a telegraph instrument, one of 12 which were
sent out to Kharatoum in 1878 by the firm to the order of
the late General Gordon. The instrument was found after the
battle of Omdurman in a hut in working condition.
In the absence of Lord Sunfield, President of the club, the
chair was taken by Mr Laurence Cowen, the honorary
secretary at the luncheon, which was served in the club's
dining room. About 200 persons were present, including
Sir Chib Chen Lo Fengshun, Chinese Minister Plen-
ipotentiary Lord Donoughmore, Sir Horace Tower, K.C.M.G.,
Agent General for Queensland, and others. His Excellency pro-
of a few remarks said that he looked upon the English
press as a great instrument for good, that he was a great
admirer of our literature and had read many of our
philosophical, poetical, and scientific works, and that he
was having Lord Charles Beresford's work on China
translated for use in his own country. In his opinion it
was one of his most important duties to bring to the
knowledge of his fellow countrymen what had been and
what was being done in this country. He took the oppor-
tunity of indicating not only the friendly feeling he bore
towards this country but his sense of the importance of
bringing the manufacturers of the British Empire into
closer commercial touch with the 400,000,000 inhabitants
of the empire which he represented—His Excellency pro-
poses to make a tour of the manufacturing districts in Great
Britain, and according to a leading article in this week's issue
of *Commerce* it is his intention further to return the com-
pliment paid by Lord Charles Beresford to China by writing
a book which shall record his impressions of industrial
Britain and which is intended to be an official report on the
manufacturing resources of this country to his Government.

ISOLATION HOSPITAL FOR BRISTOL—THE NEW

isolation hospital at Ham Green is to be opened for the recep-
tion of patients on July 17th. The hospital and grounds
cover about 20 acres of land and will provide accommodation
for 165 patients. The buildings at present erected consist
of four pavilions and an isolation ward which will accom-
modate 76 cases. The cost has been estimated at about
£30,000.

Obituary.

LAWSON TAIT, F.R.O.S. ENG. & EDIN.

THE unexpected death of Mr Lawson Tait has created a widespread feeling of regret and has removed from the domain of surgery a light which has shone with singular force and brilliancy for a number of years. Mr Tait was present at the opening of the new railway station at Droitwich on June 3rd, and at the subsequent luncheon, in response to a call for his name when the toast of "The Visitors" was proposed, he rose and spoke the following words: "I came to Droitwich last night, I was quite well, I had a bath and to-day I am better." Amid laughter he resumed his seat with evidently little presage of what was so soon to come. On June 13th he was seized with pain and serious symptoms connected with the kidneys, and died at three o'clock in the afternoon. The renal disease was of some duration, for two years ago a calculus became impacted in his urethra. This was removed by a surgical colleague, but his health had been indifferent since, and no doubt the disease which ultimately caused his death was progressing in the interval.

Lawson Tait was born in Edinburgh in 1845 and was consequently only in his fifty-fifth year at the time of his death. Educated at Heriot's Hospital School in that city he subsequently became a student in medicine at the University and Extra-mural School and qualified as L.R.O.S. Edin. in 1866, becoming a Fellow of the Royal College of Surgeons of Edinburgh, in 1870 and of the Royal College of Surgeons of England in 1871. It was during his student days when associated closely with Mr Alex. McKenzie Edwards, a rapid and brilliant operating surgeon, and afterwards with Sir James Simpson, that he imbibed and fostered that enthusiasm for surgery which led him to what may fairly be termed world-wide renown. After three years at Wakefield, where he was house surgeon to the hospital, he went to Birmingham in 1870, taking a house in the suburbs. He soon afterwards removed to the centre of the town and by his indomitable energy and persistence, as well as by early association with influential fellow residents, became a prominent citizen and a rapidly rising surgeon. It was about this time that the opportunity was given to his powers by the establishment of the Hospital for Women. The project met with considerable opposition within the ranks of the medical profession, but the great mortality which some 30 years ago attended abdominal operations proved a strong argument with the public for the advisability of supporting a special hospital where, it was urged, special care could be given to such cases. Throwing himself with characteristic vigour into the movement all opposition was borne down and Tait was appointed one of the first surgeons to the hospital. It was at this date that he became a Fellow of the Royal College of Surgeons of England. In the Hospital for Women and in his own private hospital in the Crescent at Birmingham he soon obtained a large practice in abdominal operations, devising surgical methods which have gone far to revolutionise the treatment of the special diseases of women throughout the world. In 1873 he published his first work on Diseases of the Ovaries for which the Hastings Gold Medal was awarded. His method of performing ovariectomy operations without the clamp (until Tait's time almost universally employed) was attended with exceptional success. In the removal of diseased Fallopian tubes and pelvic abscesses he enunciated new views of pathology which have since received general acceptance, and with the investigation of ectopic gestations his name has been honourably connected as a great pioneer and original worker. In perineal operations he simplified and practised a ready method of repairing the tissues which has been generally followed, and by numerous and almost incessant contributions to the surgery of the female pelvic organs he advocated and emphasised operative modifications founded upon the outcome of an exceptional and versatile power of intuition. Nor was his genius confined to the sphere of gynaecology alone, for he operated in other directions, notably for the removal of gall stones, with original design and ability. Tait was, indeed, a rapid and brilliant operator, quick in judgment, fertile in resources, and apt in dealing with difficulties. Not

giving, so much profound attention to diagnosis, which he knew and felt was often problematical, he solved the question in abdominal operations by his insight into the pathological conditions present and by bold and often daring procedure he met with results which signalled his skill and power of overcoming difficulties and complications. Self-confident and capable, he was always aware that his strength was exhibited in the face of danger, and he inspired the feeling in those with whom he was associated that fear was unknown to him and that nothing was ever done by him in response to so unreasonable a sentiment.

Lawson Tait was appointed first Professor of Gynaecology at Mason University College and afterwards bailiff and trustee of that institution, where he always espoused the cause of medical education with foresight and effect. In 1890 his surgical position was recognised by the British Medical Association, before which body he was chosen to deliver the address in surgery at the annual meeting held in Birmingham. That address reads now as a perfect revelation of the man. In it we see his clear headedness, his pugnacity, his contempt for detail, his worship of good surgery and his glory in his own talents. To read it is to understand at once his enormous success as well as his more than occasional failure. Speaking in Birmingham he invited the attention of his hearers to the dexterity of the Birmingham button-cutter. He warned modern surgeons against attaching undue importance to elaborate book learning, speaking with open contempt of the man who without mechanical skill and on the strength of a needlessly perfect scientific education embarks upon operative procedure. That he unduly emphasised his point, regarding surgery too much in the sense of the craft and being too sweeping in his condemnation of science as an element in the training of the medical student is possible, but it is undoubted that some of the strictures which he at that time considered it to be his duty to pass upon the prevailing trend of professional education were, and are, deserved. We commend the perusal of this address to all. Many of the topics are controversial and on many of them our readers might not, as we do not, take the dead orator's view exactly, but in the main Tait was right, and his remarkably pithy and vigorous words make admirable reading.

In public life Lawson Tait never abated in his unceasing zeal and efforts to fulfil the objects which he had in view. As a member of the town council of Birmingham he took an important part in the health and sanitary deliberations of the council, doing good work upon the Asylums Committee and as chairman of the Health Committee. A prominent and enthusiastic politician, he propounded his views after the split of the Liberal party over the Home Rule question with his usual force, and fought as a Gladstonian Liberal in Unionist Birmingham for a seat in Parliament, where in a contest with Mr Jesse Collings he was hopelessly defeated. His restlessness of disposition and tenacity of purpose led him into association with most of the public movements during his residence in the town, in all of which he was found to be a dangerous opponent and an aggressive champion of the cause which he took up. In this life of constant struggle he made many friends and also many foes, for he never took trouble to conciliate those who differed from him, with relentless criticism continuing to fall upon his adversaries with heavy hostility. It was difficult to cross swords with him in controversy as he depended less upon the facts than upon the object which he had in view for a justification of anything he might say. Hence his methods often led to avoidance of antagonism on the part of others. But, as a rule, Tait's adversaries were ready to allow to their doughty antagonist full credit for courage and for a fine desire to fight on the side, as he conceived it, of the weak and the oppressed. He dearly loved a losing cause and a consensus of accepted opinion was anathema maranatha to him. Had there been a seriously divided opinion in the medical profession upon the question of the scientific value of experiments on sub-human animal life Tait would have been less ardent in the cause of anti vivisection and more keen to sift the statements and weigh the alleged arguments of the non-scientific persons who welcomed him so warmly to their ranks. Had Gladstonian Liberalism stood a practical chance at Birmingham half the charm for Tait in contesting for the honour of the Parliamentary representation of the Bordesley division would have been absent. Had any other surgeon possessing a tithe of his position or professional skill thrown doubt on the value of the antiseptic methods Tait would have been far less ready to appear as a public sceptic, even though

LAWSON TAIT, F.R.S. Eng. & Edin.

Analysis of DASMAIL AND CO'S FEMALE CORRECTIVE MIXTURE SPECIAL SS

Specific gravity, 998
Water, 95 79 per cent
Oil, 4 00 per cent
Organic extractives, 0 16 per cent
Mineral matter, 0 05 per cent

The fluid had a faintly alkaline reaction. The oil floating upon the top of the mixture was drawn off and its boiling point was ascertained to be 314° F, its specific gravity being 0 863. These factors are practically identical with those obtained with the oil of pinus pumilio and it possessed a fragrant smell indistinguishable from that of this oil. The bright orange colour of the fluid, which was quite opalescent, was found to be due to saffron. Saffron is described as anodyne, cordial, emmenagogue, and exhilarant, and is clearly a drug that cannot be taken with impunity by women suffering from the only common cause of menstrual obstructions—pregnancy.

N

The advertisement of this person is of very frequent occurrence. It usually runs as follows—

WOMEN'S AILMENTS

IRREGULARITIES.—A Lady, having tried in vain every advertised remedy has at last discovered a Simple Cure which will act in a few hours, no matter how stubborn the case. Bona fide sufferers can get it Free of Charge by enclosing stamped envelope. Don't experiment with Worthless Pills, Mixtures, Cones, and other injurious nostrums.—Write at once with full hope and confidence, to Mrs O ST CLAIR, 48, Southampton buildings, Chancery lane, London.

The medicine which we received from Mrs St Clair was accompanied by a pamphlet to which we have already referred as putting beyond question the nature of the derangement which she professes to cure, for it offers "for preventing irregularities" the ordinary indiarubber and other goods advertised for the prevention of conception. We also note among Mrs St Clair's testimonials one signed "Miss R" which commences thus "It is with unspeakable joy I write to tell you thanks to your wonderful specific all came right Sunday after taking six doses." The satisfaction of a patient for whom an emmenagogue has been successfully prescribed does not as a rule take the form of "unspeakable joy."

Analysis of Mrs ST. CLAIR'S MIXTURE

Specific gravity, 1005
Water, 99 60 per cent
Organic extractives, 0 38 per cent
Mineral matter, 0 02

Nothing in particular could be detected in this mixture. It is a simple herbal infusion. As will be seen the total extractive matters only amounted to 0 4 per cent, a great part of which was due, as analysis showed, to saccharine matters. On releasing the cork from the bottle it was evident that there was pressure inside and bubbles of gas ascended through the fluid. In short, it behaved like most herbal infusions and had commenced to ferment. According to the appearance of the liquid there is no necessity to "shake the bottle" as is enjoined on the label. The "mixture" was a brownish fluid possessing little character in regard either to taste or smell and monstrously expensive at 6s 6d the bottle.

Some time ago we received from the editor of one of our best provincial journals a letter complaining that we had made a mistake in inserting the name of his paper in our list of those printing objectionable advertisements. This gentleman added that he was in the habit of refusing all such advertisements and invited us to point out that of which we complained. Our answer was to send him the following advertisement cut from his newspaper, and as we have not received further remonstrance from him, we conclude that its character is to some extent recognised even by those who do not advertise the more flagrant solicitations of Frain, Dasmall, and the like.

TOWLE'S PENNYROYAL & STEEL PILLS FOR FEMALES

QUICKLY CORRECT ALL IRREGULARITIES REMOVE ALL OBSTRUCTIONS, and relieve the distressing symptoms so prevalent with the sex. Boxes 1/1s & 2/6 (contains three times the quantity), of all Chemists. Sent anywhere on receipt of 15s or 34 stamps, by E T TOWLE & Co Manufacturers, Dryden street, Nottingham.

Beware of imitations, injurious and worthless

This advertisement is of very frequent occurrence, indeed, the firm in question must be among the largest advertisers of the class of goods which we have so often defined as being liable to be bought by pregnant women desirous of procuring abortion upon themselves. It will be observed that in addition to the statement that the pills "remove all obstructions" there is the statement that they contain pennyroyal—a drug not now used in medical practice, but once enjoying a wide and long established reputation among the poorer classes as an abortifacient. Those who purchase Towle's pills will find them accompanied by a paper extolling their merits for the cure of "sick headache, whites, eruptions, and sallowness of the skin, depression of spirits, languor, lassitude, hysteria, and kindred complaints," while their power to correct "all irregularities" is again dwelt upon and they are styled in large capitals "Woman's unfailing Friend." A second leaflet announces that "Stronger Pills specially prepared for obstinate cases may be sent where required, secure and free from observation, to any part of the United Kingdom." We are not aware, however, of any reason why a woman afflicted with sick headache or any of the other complaints enumerated, none of which can fairly be said to bring disgrace, should be attracted by a suggestion of secrecy, or why even if her case may rank as "obstinate" she should be anxious to have her medicine sent "free from observation."

Analysis of TOWLE'S PENNYROYAL AND STEEL PILLS

Moisture, 6 20 per cent
Mineral matter, 57 58 per cent
Organic extractives, 36 22 per cent

On examining the mineral matter it proved to contain both iron and sulphates and had also a distinctly alkaline reaction. The pills were coated with a white substance like stearate. Very little indication was given of the presence of oleum pulegi (pennyroyal) but reactions were obtained pointing to Barbary aloes.

METROPOLITAN HOSPITAL SUNDAY FUND

THE following were among the principal amounts received at the Mansion House during the past week in aid of this Fund. The total now exceeds £35,000—

IN 33 of the largest English towns 6693 births and 3567 deaths were registered during the week ending June 17th. The annual rate of mortality in these towns which had

HEALTH OF ENGLISH TOWNS

In 33 of the largest English towns 6632 births and 3677 deaths were registered during the week ending June 17th. The annual rate of mortality in these towns which had been 17 and 16·4 per 1000 in the two preceding weeks, rose again last week to 16·5. In London the rate was

The lowest rates in the 32 towns were 9-10 in Crofton, 9.3 in Cardiff, 11.4 in Bingley, and 11.8 in West-Ham, the highest rates were 20.8 in Hainay, 21.7 in Brimley, 22.0 in Ashford, and 21.8 in Wanchester. The 2007 rates in Manchester were 11.5 per 1000, while it averaged 17.4 in the 32 provincial towns.

[illegible]

recorded just west in Brighton, in the other towns they caused the latest deaths here in Cardif, Bolton, Huddersfield, and Sunderland, and the highest rates in Swansea, The greatest mortality from measles occurred in Liverpool and in Manchester, from Plymouth, Sefton Hall and Garsdale, and from whooping cough in

The 83 deaths from diphtheria included 35 in London, 10 in Sheffield, six in Leicester and in Leeds, four in Liverpool, and one in Hull, but not one in any other of the 33 large towns, and only one case registered in Liverpool and one in Hull. One fatal case of small pox was registered in Liverpool and one in Hull, but not one in any other of the 33 large towns, and only one case registered in Liverpool and one in Hull.

Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last (June 17th) was 2320 to 2269 at the end of the four preceding weeks, 262 new cases were admitted during the week, against 229, 260, and 278 in the three previous weeks.

The deaths in London were certified as the primary cause of 13 respiratory organs in London, which had been 22.40 and 216 in the two preceding weeks further decreased last week to 207. The causes of the deaths in the 33 towns were not 10 per cent., of the deaths in the corrected average

a corner. All the causes of death were duly certified in Nottingham, Bradford, Leeds, Hull, and in 16 other smaller towns. The largest proportions of uncerberged deaths were registered in West Ham, Birmingham, Leicester, and Halifax.

The annual rate of mortality in the eight Scotch towns, which had been 19.9 and 18.9 per 1000 in the two preceding years, further declined to 17.9 during the week ending June 17th, but was 1.4 per 1000 above the mean rate during the same period in the 33 large English towns.

HEALTH OF SCOTCH TOWNS

The following table shows the results of the survey of the 1000 most common words in the English language, as given by the Oxford English Dictionary. The words are arranged in alphabetical order, and the number of occurrences of each word is given in the second column. The words are arranged in alphabetical order, and the number of occurrences of each word is given in the second column.

to an annual rate of 2.2 per 1000, which was 0.3 above the mean rate last year, from the same dates in the 33 large English towns. The fatal cases of measles, which had increased from 11 to 25 in the three preceding years, declined again to 11 last year, of which 10 occurred in Glasgow. The 10 deaths from whooping cough, of which 10 occurred in Glasgow.

decline of six from the number in the first week, and occurred in Glasgow and three in the first case of Scotland, which had been 11 and five in the previous week, rose again to eight last week of which nine occurred in Glasgow and three in Edinburgh. The eight data related to diphtheria exceeded the number recorded in any recent week and indicated a further rise.

of 1, fewer three occurred in Glasgow where the death from Dundee, and two in Aberdeen. Of the five fatal cases in Glasgow two in

THE PHILIPPINE CAMPAIGN

The Americans, in current phraseology, do not seem to be getting "much forrader" in their conquest of the Philippines. Their engagements with the enemy are frequent and so far they have always been favourable to their side. They repeatedly attack their opponents and drive them out of their entrenchments with much loss only to find them soon reappearing, however, somewhere else. What with the heat and rains, the frequent small fights, the labour and unrest of their troops, there must, we imagine, be a good deal of sickness in the American force. In connexion with this subject we may advert to Mr. Poultny Bigelow's recent lecture on "The Yankee Soldier" at the Royal United Service Institution. While most justly and properly eulogising the conduct and bravery of the American regular troops in the recent war the lecturer gave a description of the lamentable effects of the political system and influences at work in the United States Army, as illustrated by the bragging of political soldiers who became intimate with newspaper reporters and so managed to keep their names before the American public, the passing over of qualified officers trained at West Point in favour of civilians who were appointed to the command of volunteer troops in the field, the breakdown of the supply departments and the absence of all proper organisation observable. Military fitness and training, according to the lecturer, apparently gave no claim to selection for appointments in the United States volunteers in competition with political influence. The lecturer gave, in brief, such a lamentable revelation of the state of things as to cause his audience to "raise the eyebrows of astonishment" and ask themselves how such an eminently sagacious and practical people as the Americans could tolerate the evils that were alleged to exist. General Miles has been publishing some papers in the *North American Review* on "The War with Spain." He describes the fighting at San Juan and in the Santiago campaign. The American losses in these encounters with the Spaniards amounted from July 1st to the 12th to some 1500 killed and wounded out of a total force of about 18,000. General Miles very pertinently remarks that an army in the field in these days is almost powerless without very efficient administrative departments. We may add that we have but little official information as to what was the actual state of the medical, transport, and supply services during the late Spanish American war or as to the losses that occurred from disease and the nature of those diseases which prevailed.

THE ALDERSHOT MILK SUPPLY

As our readers are aware the state of the sewage farm at Aldershot was a frequent subject of complaint in past years and quite recently the War Office authorities were somewhat

severely called to account in the House of Commons on the question of the proposed sale of milk from the dairy of that farm. That the sewage farm at Aldershot was but little better than a sewage swamp a few years ago would not, we suppose, be denied. But since that time it has been put under an entirely new management, great alterations and improvements have been effected and are still being carried out, and a very notable change in its condition has consequently taken place. As regards the milk supply the War Office authorities urged that there was no evidence to show that milk obtained from a well managed farm was, in virtue of its origin, a source of disease, citing the case of Birmingham as an example, and that they were acting with the approval of their own sanitary advisers. Still, they were quite ready to submit the matter to some independent authority. Dr Andrewes of St Bartholomew's Hospital was, on the advice of Sir Richard Thorne, selected for the purpose. He was asked to examine the conditions of the Aldershot camp sewage farm and advise whether any of the circumstances there present are such as to throw doubts upon the safety of making use of the milk produced upon the farm for human consumption. Dr Andrewes, after full and independent inquiry, has made his report, which quite bears out the view taken by the War Office, consequently there can be no objection to employ the farm profitably. It is notorious that dairies exist in connexion with many sewage farms in this and other countries and that the sale of milk forms an important item of income. If proper precautions be taken no harm results. Dr Andrewes found no conditions on the Aldershot farm liable to render the milk more dangerous for human consumption than that obtained from any other well managed sewage farm.

THE PEACE CONFERENCE

The deliberations of the Peace Conference at The Hague, notwithstanding the general desire which, it may be assumed, animated the delegates, are not, we fear, likely to effect much practical good. So many conflicting interests are involved and the whole subject is so complicated and surrounded with difficulties that no general agreement upon many points seems probable. The scheme of international arbitration through the instrumentality of an organised arbitration tribunal, although generally acceptable to the Great Powers, has not yet received the assent of Germany. Should it do so this will be the only important gain realised by the Conference, it is at least a step on the road to peace. The project for the limitation of armaments proved futile at an early stage of the proceedings and the discussions regarding proposed modifications of the Geneva and Brussels Conventions, in which members of the medical services are most interested, gave rise to attacks upon some of our British methods of strategy and tactics. But many of the delegates apparently did not really know the true character of the Dum Dum bullet, and as regards naval warfare, in which Britain is mainly, if not supremely, concerned, the adoption of some of the proposals at the Conference would, it is believed, greatly hamper this country. It is lamentable that the result of the Czar's humane enterprise—for no one doubts that monarch's personal humanity and *bona fides* as apart from the traditional military policy of the Russian Empire—should not be greater, but the outcome of the International Conference was foreseen from the beginning.

THE ROYAL ARMY MEDICAL CORPS MANUAL

In the new Manual for the Royal Army Medical Corps which has recently been published considerable alterations and improvements have been made in stretcher drill. No 4 bearer is now in the rear rank and acts as a supernumerary as long as the company is in close order. In moving to a flank the stretcher is carried at the slope by No 2 bearer only. In extended order No 4 bearer takes his post on the opposite side of the stretcher so that the changing of the numbers is much simplified. A new method of lifting the wounded on stretchers as suggested by the staff of the Volunteer Ambulance School of Instruction has been adopted. Each squad halts when No 1 arrives one pace from the patient's head, Nos 2 and 3 correctly covering in a line with the patient. There is no change in the hand seat drill. In the wagon drill Nos 2 and 4 are now on the right of the stretcher. In the plans of the dressing station and field hospital camp a new operating tent is shown, the length of which is 20 feet, the width 14 feet—this gives far more room than did the old pattern bell tent. Semaphore signalling has

Compared with previous returns these figures show a marked decline of the epidemic. They must not be taken as accurate for they under estimate to a large amount the fatality from this disease. With regard to the city of Calcutta it is curious to observe that notwithstanding the existence of plague as well as a considerable number of deaths which are returned as suspected plague the general death rate is only at the rate of 28.2 per 1000 per annum against an average of 30.5 for the past five years.

In Bombay city the deaths from plague have now become reduced to from 15 to 20 per day, but as the weekly mortality is considerably more than this proportion above the average large numbers of cases must still continue to be concealed and to be registered under other diseases.

An outbreak of plague is reported at Penang and a fresh outbreak is reported at Belgaum. The number of cases of plague in Hong Kong has doubled during the past week.

The cholera outbreak at Karachi shows signs of decided abatement, but only after nearly 1500 people have fallen victims to it and a maximum of over 250 cases a day has been reached. It has been a very serious visitation not only as regards numbers but in the high percentage of deaths to attacks. The explanation of its origin seems to be as follows. Some 8000 famishing Mekranis driven from their homes in the Beluch State of Lus Bayla by scarcity of food encamped in the outskirts of the town with a number of others of the same class. There is a sewage farm near at hand somewhat above the level of the spot where these people congregated. They drank water from the wells thereabouts and being in low condition they were in a state favourable for the spread of cholera. Now that the Mahr public supply is extended to the stricken suburbs and the wells are closed the disease is abating, and as it has not extended to any district possessing a good water supply the argument which connects the outbreak of cholera with water contamination seems highly probable. There is also a burial-ground near the spot chosen by these people for encampment.

Some successful inoculations against rinderpest have been carried out recently in the Bareilly district by Captain Rogers of the Imperial Bacteriological Laboratory at Muktesar. The serum method has been employed. This appears to have prophylactic as well as curative properties. In one of the villages more than half the cattle are said to have been attacked. Of the survivors a considerable proportion were inoculated at the request of the villagers and none of the animals so treated subsequently contracted the disease although several cases with some deaths took place among the remainder of the uninoculated animals. A few cases in the early stage of the disease were treated with the serum and it is said that equally good results were obtained. The account states that the immunity is produced much more quickly than in the bile process and it is said also to last much longer.

May 31st.

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

Consulting Institution

THE following notice of resolutions has been issued by Dr Saundby, chairman of a meeting of consultants held on June 15th. They are to be submitted to a general meeting of the profession called for June 23rd.

1. That this meeting of registered medical practitioners residing in or near Birmingham objects to the proposed consulting institution on the following grounds:—(a) that it is proposed that non medical employers shall exploit the services of medical men—in other words, shall employ medical men to earn fees pay them by salary and deal with the proceeds at their own pleasure (b) that no restriction is proposed as to the class of persons to be received as patients so that persons well able to afford the usual consultation fees would obtain a concession to which they have no claim (c) that it is proposed to incorporate the institution as a limited company to carry on the business of physicians and surgeons, and that this is contrary to the Bill which has passed the House of Lords entitled An Act to Amend the Companies Acts, which has received the support of the General Medical Council and the British Medical Association and (d) that such an institution would assuredly seek to procure patients by advertising and canvassing in contravention of professional rules and any practitioner holding service in it would render himself liable to the censure of the General Medical Council.

2. That this meeting records its opinion that no registered medical practitioner should take office in an institution open to these objections.

Crematorium Meeting

A largely attended meeting was held on June 14th in the

Council House to further the interests of cremation and to provide a crematorium in Birmingham. Alderman Johnson presided. The Bishop of Coventry dealt with the religious aspect of the question, in which he sought to dispel the popular sentiments on the subject of earth burial. Sir Charles Cameron gave his experience as derived from observation in Glasgow and combated the objections made on the ground of expense, detection of crime, and other details. He strongly urged the establishment of a properly regulated association. Mr J Hervay Simpson, secretary of the Manchester Crematorium, also added information as to the manner in which the various processes leading to the ultimate destruction of the body can readily be obtained. Resolutions in favour were unanimously passed.

Need for Reform

A gruesome discovery of the bodies of nine infants was lately made in a cellar in one of the poorer suburbs of the town. The occupant of the house was a midwife whose avocations had been interfered with by her illness hence her inability to see that the bodies were duly buried. The difficulty of dealing with such cases was pointed out by the coroner who showed that in case of still born children the birth is not registered, therefore no burial order is required from the registrar. Curiously there is no law to compel a corpse to be buried so long as no nuisance is caused to public health. The coroner has pointed out the need of some legislative enactment to deal with such cases. Certainly it would appear that it is necessary in such instances as the one recorded.

Mason University College Pathological Department

During the past two or three years the growth of this department has been of a remarkable character owing to the very large and increasing amount of bacteriological work which has been carried on for the various sanitary authorities in the Midlands. Two years ago the college undertook to conduct the examinations of throat secretions from cases of suspected diphtheria for the Health Committee of the City Council of Birmingham, and since that time the system has extended to the counties of Staffordshire and Shropshire and to most of the corporations within 20 miles of Birmingham, the scheme in some instances including typhoid fever and tuberculosis as well as diphtheria. The number of students preparing for diplomas in public health has increased 50 per cent and special complete courses in bacteriology have been arranged for them. Special bacteriological instruction of an elementary character is also given to general practitioners. The work having become too heavy and important for anyone but a specialist devoting the whole of his time to it, the council of the college at their last meeting appointed Dr R. F. C. Leith as Professor of Pathology and Bacteriology to give his entire services to the department. Dr Leith is an assistant physician to the Royal Infirmary of Edinburgh, and Lecturer on Pathology and Bacteriology at Surgeons' Hall, Edinburgh. As a teacher he has acquired a very high reputation and his contributions to medical literature show his capacity in the field of research. Dr Leith will commence his duties in the new laboratory, which is being built for him, in October next.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

School of Tropical Diseases Inaugural Lecture by Major Ross, I.M.S., on the Possibility of Extirpating Malaria Expedition to West Africa

MAJOR RONALD ROSS, the lecturer in tropical diseases at University College, gave his inaugural lecture on June 12th in the Arts Theatre of the College. The chair was occupied by Principal Glazebrook and the audience included the Lord Mayor and many prominent citizens. Major Ross observed that the Liverpool School of Tropical Diseases had been established at a most favourable time, bearing in mind the recent discoveries for the extirpation of malaria. It must not be supposed that malaria would be extirpated all over the world. They were now endeavouring to extirpate it in a certain sphere and if success attended their efforts they would consider it a satisfactory result. He had no doubt that a similar result could

Commons and the replies (reported in THE LANCET of April 1st, p 935) were in Sir Charles Cameron's opinion entirely unsatisfactory. No doubt the true remedy for abuses of this kind is the passing of Mr Alexander Cross's Bill making Poor law medical officers in Scotland removeable only with the sanction of the Local Government Board of Scotland.

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Weir Legacy to the Dublin Hospitals

THE arrangements for the distribution of Mr Weir's munificent legacy of £100,000 to the hospitals of Dublin have been followed with much interest here. The three executors were directed by the terms of the will to advertise for claimants under it, and claims have been advanced by no less than 43 different hospitals and charitable institutions for a share in the donation. The legal interpretation of the word "hospital" used in the will was open to question and it became necessary to obtain a decision from the Vice-Chancellor on the matter. That decision was promulgated on May 4th last and declared that 34 out of the 43 applicants were within the scope of the bounty. Since that date four other institutions have been included from a batch of eight who sent in application quite recently and the money is now being divided among 38 hospitals of Dublin and its vicinity. In February last £10,000 were given to 10 Dublin hospitals and charitable institutions in equal shares of £1,000. The remaining £90,000 are now being distributed on the principles laid down by the Vice-Chancellor and in portions settled at the discretion of the executors. The precise sums to be allocated to each of the charities has not yet been made public, but the registrar of Mercers' Hospital has written to the morning papers of June 19th to acknowledge the receipt of £5,000 from the executors, while the Governors of Dr Stevens' Hospital have just publicly acknowledged the receipt of a like sum.

The Legal Position of the Public Analysts to the County Councils in Ireland

At a meeting of the Limerick County Council held on June 17th a letter was read from Sir Charles Cameron protesting against the action of the county council in proposing to dispense with his services as public analyst, and stating that he was advised that dismissal from the office was equivalent to the abolition of the office. He mentioned, moreover, that if the council decided on that course he was willing to retire on being paid £500. It was agreed to refer the matter to a committee, the council having been informed by the Local Government Board that they had no power to dispense with the services of the public analyst unless he himself wished to retire.

The Finances of the Irish Branch Council

At the late meeting of the General Medical Council a discussion which is of the utmost interest to the medical profession in Ireland took place on June 8th on the finances of the Irish Branch Council. It would appear that the assets of the Irish Branch Council have dropped from £301 18s. 5d in 1896 to £284 9s. 10d in 1898, and it was only natural that the Irish representatives (all of whom reside in Dublin) should be asked by the President to explain how in two years there should be such an extraordinary drop in their receipts of £517. It would appear also that at one time the Irish Branch Council had as much as £10,000 to its credit, now there is only a balance of £200. The explanation is that so many Irish students now go to Scotland for their degrees and qualifications, and as they register there the fees for such registration are lost to the Irish Branch Council. Everyone admits these facts, the extraordinary thing is that when one looks at the names of candidates who pass the final examinations of the Scotch Colleges of Physicians and Surgeons (the "double qual," as students call it) it is evident that there is an exodus from all parts of the country. The three largest medical schools in Ireland at present are Trinity, the Catholic University, and Belfast, and at the present time a large number of those students of the Catholic School of Medicine and of the Belfast Medical School who do not go to the Royal University of Ireland migrate to the qualifying boards in Scotland. The same thing applies

to Cork. The curious point is that in Dublin there are, in addition to the two universities (Trinity and the Royal), the other medical qualifying bodies, the Royal College of Physicians of Ireland, the Royal College of Surgeons in Ireland, and the Apothecaries Hall of Ireland, and yet the great majority of Irish medical students at the present time who do not graduate at the Irish universities migrate to Scotland. In the General Medical Council Sir Dyce Duckworth asked why such a large number of Irish students should go to Scotland to seek a diploma and Sir Christopher Nixon replied "The education is cheaper and the examinations are easier to pass"—a statement which was contradicted promptly by Dr McVail. There can be no question that there is a great deal of truth in what Sir Christopher Nixon has stated, but thoughtful men must see that there are other elements to be considered. What, for instance, is the reason why the number of Irish students going to Scotland has so largely increased in recent years? Have the Irish medical examinations suddenly become harder to pass and has education here become markedly dearer in the last two years? I think the time has come when all Irish medical men who are patriotic, and especially those who are engaged in the teaching of the coming race of medical men, should meet and discuss the question raised at the General Medical Council as to the reason why such a large number of young Irish medical students do not qualify in their own country but migrate to Scotland, and in fairness to all not merely the teachers but the students themselves should be asked the cause of this extraordinary exodus.

A Case of Sporadic Cerebro-spinal Meningitis in Cork

A nursing sister who had been nursing a patient at Queenstown became very ill and was removed to Cork for treatment. Two members of the profession in Cork saw her in consultation and found that she was suffering from cerebro spinal meningitis. Nearly the whole of her body was covered with black spots and within a very few days she succumbed to the disease. The sanitary authorities were called in and fortunately no other case has since occurred. Amongst the general public there was at first an idea that she may have contracted the disease in Queenstown where it may have been brought by a sailor from a foreign port, but inquiries have not elicited any information in confirmation of that opinion. Besides, the fact that the disease is now generally regarded as not being directly contagious is rather against that theory.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Case of Dr Lassalle

LAST year the police-court at Pau sentenced Dr Lassalle to two months' imprisonment for manslaughter (*homicide par imprudence*). He had performed an operation for the removal of a large fibroma from a woman named Treveran residing in the commune of Coarrage. She died a few hours afterwards and at the necropsy a pair of forceps which had been forgotten was found in the cavity of the uterus. On the completion of his sentence Dr Lassalle made an application to the authorities declaring that Madame Treveran died from poisoning by nuxvomica and not from anything connected with the operation. On the day of her death a bottle containing nuxvomica was seized in the possession of a woman named Franck, a fortune teller of ill repute, who was convicted of illegal practice in medicine on the same day that Dr Lassalle was convicted of manslaughter. As the statement in question seemed to have reference to M. Treveran, the husband of the deceased, he prosecuted Dr Lassalle before the police-court at Pau but the case was dismissed. This decision was appealed against both by M. Treveran and by Dr Lassalle, the latter of whom claimed that his case should be reheard and the body of Madame Treveran exhumed. The court granted the application of Dr Lassalle and the matter now wears a different aspect.

Banquet to Dr Emily

Dr Emily, the naval surgeon who accompanied Major Marchand's mission and through whose assiduous care the mission enjoyed excellent health during its painful exertions, has on his return been received in Paris with the utmost honour. At the last sitting of the Academy of

a blacksmith, purchased for a few sous the biggest nail he could find, choosing the rustiest one in order that the wound might be the more formidable, had it sharpened till it became a stiletto, and lay in wait for Dr Bondi. He hung about the hospital all the next forenoon but missed his intended victim, and not till 4.15 P.M. of that day did he find the opportunity which he sought. The rest we know. This is the second murder committed by a tuberculous patient in the same hospital—the previous victim being that Sister Agostina whose tragic death some few years ago sent a thrill of horror throughout the civilised world. Her assassin, significantly enough—Romanelli by name—was (or rather is, for such “belve umane,” or human wild beasts, are not executed in Italy) a personal friend of Caioni and his motive was the same—resentment at not having the resources of the hospital expended on him after the regulation time. Such occurrences are so frequent in Italy as to call aloud for a punitive or deterrent system much more effective than that in force. THE LANCET’S suggestion¹ of flogging is one which is seriously commending itself to the Italian reformer, there being nothing which such miscreants as Romanelli, or Caioni, or Luccheni dread more than physical pain. The new laws of “Pubblica Sicurezza” now before the Legislature should certainly contain a provision of the kind, or at least one appealing more sensibly to the would-be assassin than board and lodging for life at the expense of the industrious and law-abiding citizens.

Leo XIII and Dr Mazzoni

Grateful for the continued good health—nay, more, for the prolonged life—he owes to Dr Mazzoni’s intervention four months ago, the Holy Father has just presented his portrait (of full length in oils) to that eminent surgeon, accompanying the gift with a special dedication couched in Latinity of characteristic eloquence. Besides this token of “gratitude and esteem” His Holiness in an autograph letter (also in the language of his Church) has just nominated Dr Mazzoni “Surgeon in chief to the Apostolic person.”

June 19th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND—The following gentlemen having passed the necessary examinations and having conformed to the By-laws and Regulations, have been admitted fellows of the College and have received their diplomas—

Frederick William Robinson, M.D. O.M. Aberd. Aberdeen University, Charing Cross and Guy’s Hospital, Diploma of Member dated August 4th, 1897. Fergus Menteith Ogilvie, M.D., B.O. Cantab., L.R.C.P. Lond., Cambridge University and St. George’s Hospital, Member July 29th, 1898. Arthur Gaskell (Surgeon, I.R.N.), L.R.C.P. Lond., University College Hospital, Member August 1st, 1892. William Charrington Wood, M.D. Lond., L.R.C.P. Lond., St. Mary’s Hospital, Member Feb. 8th, 1894. Frederick Newfield Cookson, M.D. Lond., L.R.C.P. Lond., Middlesex Hospital, Member May 10th, 1894. Herbert Johann Scharlieb, M.D., B.S. Lond., L.R.C.P. Lond., University College Hospital, Member July 30th, 1894. Stanley Copley, L.R.C.P. Lond., Guy’s Hospital, Member Nov. 8th, 1894. Felix Bolton Carter, M.D. Lond., L.R.C.P. Lond., University College Hospital, Member July 29th, 1895. Frederick Riley, M.B., B.S. Lond., L.R.C.P. Lond., Westminster Hospital, Member July 29th, 1895. Alfred William Sanders, M.D. Lond., L.R.C.P. Lond., St. Mary’s Hospital, Member July 29th, 1895. Archibald Robert John Douglas, M.B., B.S. Lond., L.R.C.P. Lond., St. Bartholomew’s Hospital, Member May 14th, 1896. Angelo Mattes Orabtree, L.R.C.P. Lond., St. Bartholomew’s Hospital, Member August 4th, 1896. John Thomas Hewetson, M.B., O.M. Edin., L.R.C.P. Lond., Edinburgh University, King’s College, and St. Bartholomew’s Hospital, Member August 4th, 1896. Alexander Benjamin Tucker, M.B. Lond., L.R.C.P. Lond., St. Bartholomew’s Hospital, Member August 4th, 1896. Sidney Herbert Berry, M.B. Lond., L.R.C.P. Lond., St. Bartholomew’s and Charing Cross Hospital, Member Feb. 11th, 1897. Edward Joseph Fox, B.Sc. Lond., L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester, and St. Bartholomew’s Hospital, Member Feb. 11th, 1897. William Joshua Harding, M.D. Lond., L.R.C.P. Lond., St. Bartholomew’s and Westminster Hospital, Member Feb. 11th, 1897. George Tristram Watson, M.A. M.B. and B.O. Camb., L.R.C.P. Lond., St. George’s Hospital, Member Feb. 11th, 1897. John James Bruns, M.B., O.M. Edin., L.R.C.P. Lond., Edinburgh University, Mason College and General Infirmary, Birmingham, Member May 13th, 1897. Henry Simpson Newland, M.B. O.M. Adel., L.R.C.P. Lond., Adelaide University and London Hospital, Member July 29th, 1897. Maurice Vincent Dea, M.B. O.M., L.R.C.P. Lond., Edinburgh University, King’s College and St. Mary’s Hospital, Member Feb. 10th, 1898. James Batterby, L.R.C.P. Lond., St. Mungo’s College and Royal Infirmary Glasgow, Member May 4th, 1898. Peter Lewis Daniel,

L.R.C.P. Lond., Charing Cross Hospital, Member May 4th, 1898. Henry Thomas Hadley Williams, M.D. Lond., Canada, L.N. O.P. Lond., Western University, Ontario, and St. Bartholomew’s Hospital, Member August 2nd, 1898. Bland Stokes Whitley, M.D. Dub., M.R.C.P. Lond., Trinity College, Royal College of Surgeons, and Richmond Hospital Dublin, and St. George’s Hospital, not previously a Member.

Two other gentlemen passed the examination, but not having attained the legal age, will receive their diplomas at future meetings of the Council. 22 gentlemen were referred for six months and one for one year.

The last of the series of three concerts in aid of the funds of University College Hospital was held in the Botanical Theatre, University College, on June 16th, before a crowded and fashionable audience.

MR T BOWHILL, F.R.C.V.S., has resigned his position as Bacteriologist to the Glamorgan County Council. The appointment of his successor will be left to a joint committee of the Cardiff Corporation and the Glamorgan County Council.

THE CHEMISTS’ EXHIBITION—The fact that this exhibition which is now held annually can only find proper accommodation in the Agricultural Hall, Islington, is some evidence of its increasing popularity and success. The Board of Trade further recognise the exhibition as an international one. This year’s event was signalled this week, the exhibition being opened on June 19th and closed on June 23rd. So far as can be gathered the attendance was a satisfactory one. There was everything on view to engage the attention of the visiting pharmacist, and this annual show should be useful to him in affording him an insight into recent developments and the direction which during the past year progress in pharmacy has taken. Pharmaceutical exhibits afford abundant material for artistic display and the exhibitors on the present occasion took every opportunity to make the exhibition attractive. Most of the leading houses in the drug trade were represented, the subjects of display being almost entirely confined to pharmacy and accessories of pharmacy. An excellent programme of music was provided by the Ladies’ Pompadour Band and demonstrations of liquid air, modern photography, and telephotography helped to make up an attractive programme. This annual exhibition appears to supply a distinct want and the organisers—the proprietors of the *British and Colonial Druggist*—may be congratulated on the success which has met their enterprising efforts.

LITERARY INTELLIGENCE—The following is a list of new books and new editions to be published by Messrs Baillière, Tindall, and Cox: “Difficult Digestion due to Displacements,” by A. Symons Eccles, M.B., O.M. Aberd., ex-President of the West London Medical-Chirurgical Society, “Artistic Anatomy of the Horse,” with 20 original plates, by H. W. Armstead, M.D., B.S. Lond., F.R.C.S. Eng., “Food Standards, with Statistics of Adulteration,” by O. H. Cribb, B.Sc., F.I.O., and O. G. Moor, M.A., F.I.O., “Dictionary of Medical Terms” (Part II, French-English), by H. De Merio, M.R.O.S. Eng., Surgeon to the French Hospital and Dispensary, “Aids to Materna Medica” (Part III), by William Murrell, M.D. Brux., F.R.O.P. Lond., M.R.O.S. Eng., Physician to, and Lecturer on Pharmacology and Therapeutics at, Westminster Hospital, “Urinary Analysis and Diagnosis by Microscopical and Chemical Examination,” with 108 original illustrations, by Louis Heitzmann, M.D., “The Roentgen Rays in Medical Work,” second edition, revised and enlarged, by David Walsh, M.D. Edin., Physician to the Western Skin Hospital, Honorary Secretary, Roentgen Society, London, “Roentgen Ray Case-book,” by the same author, “Dental Surgery,” fourth edition, by H. Sewill, M.R.O.S. Eng., L.D.S., “Hand book of Surgical Pathology,” third edition, by W. J. Walsham, M.B., O.M. Aberd., F.R.O.S. Eng., Surgeon to, and Lecturer on Surgery at, St. Bartholomew’s Hospital, Member of the Court of Examiners of the Royal College of Surgeons, “The Principles and Practice of Veterinary Surgery,” ninth edition, by W. Williams, F.R.O.V.S., F.R.S.E., Principal and Professor of Veterinary Medicine and Surgery at the New Veterinary College, Edinburgh, “Practical Guide to the Public Health Acts and Correlated Acts for Officers of Health and Inspectors of Nuisances,” second edition, by T. Whiteside Hime, B.A., M.D. Dub., late Medical Officer of Health of Sheffield and Bradford, “A Manual of Surgery,” second edition, by Wm. Rose, M.B., B.S. Lond., F.R.O.S. Eng., and Professor of Clinical Surgery in King’s College, London, and Albert Carless, M.B., M.S. Lond., F.R.O.S. Eng., Teacher of Operative Surgery in King’s College, London, Imperial Health

Notes, Short Comments, and Answers to Correspondents.

THE LABORER IS WORTHY OF HIS WIFE

Dr. G. F. BOWKIN, the coroner for West Surrey held an inquest on a woman recently when evidence was given in her favor. As the woman was a laborer, it was not surprising that the jury returned a verdict of "not guilty" in the case of the deceased.

The inquest was necessitated by the recent and sudden death of a woman aged 30 years. The husband of the deceased, a laborer, was found by the jury to be the cause of the death. The jury found that the husband had been drinking and had been violent to his wife. The jury also found that the husband had been neglectful of his wife and children.

Another case was heard at the same inquest. The husband of a woman had been drinking and had been violent to his wife. The jury found that the husband had been neglectful of his wife and children. The jury also found that the husband had been neglectful of his wife and children.

The jury in this case found that the husband had been neglectful of his wife and children. The jury also found that the husband had been neglectful of his wife and children. The jury also found that the husband had been neglectful of his wife and children.

The jury in this case found that the husband had been neglectful of his wife and children. The jury also found that the husband had been neglectful of his wife and children. The jury also found that the husband had been neglectful of his wife and children.

not at all connected with the vaccination but was an ordinary infantile skin disease which frequently occurred without vaccination at all. The calf lymph in this case was received from the Local Government Board Department after it had undergone the usual test. The calf from which it was taken was thoroughly sound and the test showed the usual result, that there was no infectious matter in it. He had received the reports of 339 vaccination officers dealing with over 3000 cases where this glycerinated calf lymph had been used and they were all entirely satisfactory. The public vaccinator did not state what was alleged against him in the question but another gentleman who was called in did make such a statement. In these circumstances he did not intend to make any inquiry.

TUESDAY JUNE 20TH.
Inoculation in India.

Sir CHARLES CAMEROY asked the Secretary of State for India whether he could lay upon the table of the House any official reports on the results of inoculation in India against cholera, typhoid and the plague.—Lord GEORGE HAMILTON: The hon. Member is aware that a Commission has for some time past been investigating the whole question of the plague in India, including that of the various forms of inoculation. I hope that their report may shortly be ready for publication and I should be disposed to await it before presenting any other papers on the subject to which the hon. Member's question refers. I should add that as regards inoculation against typhoid fever no official reports are as yet available.—Sir CHARLES CAMEROY: What about inoculation against cholera?—Lord GEORGE HAMILTON: There are certain papers, but I think it will be better to await the report of this Commission and then I shall endeavour to distribute as much information as I can.

WEDNESDAY JUNE 21ST
Inebriates Act (1893) Amendment Bill.

An attempt was made to get the second reading of this Bill but failed, a member "talking out" the Bill.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BENNETT W B F.R.C.S. Eng., has been appointed Honorary Surgeon to the Royal Orthopaedic and Spinal Hospital, vice Charles Warden, retired.
BENNETT W G L.R.O.P. Lond. M.R.C.S., has been appointed Medical Officer to the Worcester Dispensary and Provident Institution.
BOASE R. D. L.R.O.P. Lond. M.R.C.S., has been appointed Medical Officer by the Penzance Port Sanitary Authority.

It is most important that communications relating to the editorial business of THE LANCET should be addressed to the Editors, "THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the editorial staff. It is urgently necessary that attention be given to this notice.

It is an especially important factor in the development of local centers of research and development, or in the development of a new industry. The importance of the factor is not only in the fact that it is a factor in the development of a new industry, but also in the fact that it is a factor in the development of a new industry.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication. We cannot preserve or reproduce local papers containing reports or news paragraphs should be mailed and addressed "To the Sub-Editor." Letters relating to the publication, sale, and advertising department of THE LANCET should be addressed "To the Manager." We cannot undertake to return MSS not used.

he made with his successor when he succeeded to the excellent practice, 13 years ago which had been in the Raven family for, I believe a century. A more genial and honourable gentleman than Mr Henry Raven could not exist and the way his successor disposed of the practice and subsequently failed to pay the annuity under circumstances familiar to me are not conducive to an old practitioner transferring his practice to a young man under similar circumstances. Endowed with the feelings of a gentleman and punctilious to a degree on all points of professional etiquette he unfortunately placed too great confidence in the arrangement with his successor. And I do most earnestly lend my support to Mr Winter's attempt to raise a liberal fund for this old couple the more so as Mr Raven has two sisters living, both over 80 years of age whose only means now they are past farming a small holding is dependent on a charge which Mr Raven has had to meet, so that it is not too much to say that the action of his successor has jeopardised the existence of Mr and Mrs. Raven and his two old sisters—the elder one being the exact age of our beloved Queen.

I am sending my mite towards this real object of charity to Mr Winter and beseech all members of the profession to do likewise. I can vouch for the facts of the case, with which I was made familiar at the time consequent on my acquaintances with the family

I remain, Sirs, yours faithfully,

ELLIOT DAUNT,
Physician and Surgeon

June 17th 1899

A RURAL PARISH DOCTOR.

I'm a country parish doctor with about enough of pay
Just to give myself a dinner when my horse has had his hay
And I must go on a working for the pittance that I get
There's such awful competition, such a lot of human sweat
Though I often thought 'twere better if I dropped the weary load
And just stepped into the pasture from the grinding of the road
For I'm almost as familiar with the moon as with the sun,
For my work is often hardest when all others' work is done
And when each man of labour is fast sleeping in his bed
I must shift a weary body try to clear a weary head
It's no matter if the storm carries on its wings the snow,
And the heavy clouds of winter shroud in darkness all below,
And the way lies o'er the moorland where you easily miss the track,
I must carry out the order or they'll jump upon my back.
So it's a saddle up and face it, though before I'm back the night
May have given place to morning, with its raw and chilly light,
When you find your back has shivers and your feet and hands are numb,
And the feelings of exhaustion o'er your drooping spirits come
For it's not like serving Uncle when you're 'neath the parish rule,
Any man who thinks it is so—well he's thinking like a fool
And I wish he had the guardians to contend with if he broke
Through a trifling regulation then he'd find it was no joke.
For they'd buzz around and sting him as the gadfly stings the horse
When you see him in the pastures hold a wild distracted course,
For it is a rule I've noticed, in the ways of things below
That the fiercest ones in nature are the meanest of the show,
And a little brief authority if ignorance has got
Makes it just about the fiercest and the meanest of the lot
Oh, that I'd enough of practice in a private sort of way
To enable me to parish work to bid a long 'Good day';
But this awful overcrowding fairly chains one to the mill
Till you moil and shed your spirit from a body weak and ill
Then before you're hardly planted where the parson mows the grass
There are many fellows striving to the vacant place to pass.

G T W

THE CONSULTANT AND THE GENERAL PRACTITIONER.

To the Editors of THE LANCET

SIRS,—As an old subscriber to your valuable journal and in the interest of the younger members of the profession may I ask the favour of your inserting the following statement of facts in THE LANCET with an expression of opinion from yourself? It seems to me that there should be a recognised code of morals between the consultant and the general practitioner if there is to be maintained that trustful and happy spirit which ought to exist between the two branches of the profession

The case in question is as follows. My patient whom I will call Mr. A, was laid up with a serious nerve breakdown associated with some curious pains of a rheumatic character. After a while some more serious symptoms supervened such as diplopia and paralysis of the external rectus muscle of the right eye. I suggested a consultation with a member of a hospital staff and at this consultation it was decided to prolong the treatment of absolute rest for a further period of at least one month. To this the patient agreed with evident satisfaction and continuing treatment for two weeks the patient made sure but slow progress. On a certain morning after my usual visit and without giving me any intimation of his intention Mr. A got up and dressed and paid a visit to a consultant in the West-end. This gentleman was told that Mr. A was under my care and that I had seen him that morning but Mr. A brought no letter of introduction or even a card from me. The consultant, however saw him and prescribed for him, ignoring me altogether; the first intimation I had of what had taken place being a letter from the patient telling me that Dr. B (not his real initial) had seen him and agreed with me as to his state and had suggested a line of treatment. I declined to continue the case.

Surely Sirs if consultants see patients already under treatment without any letter of introduction from the medical charge it must of necessity place the general practitioner at disadvantage with his patient and, further, must generate distrust between two branches of a profession both of which work happily together. During my 30 years practice in London I have only on one or two occasions been thus treated to hear through THE LANCET the opinion of some medical profession who must be naturally interested in this important

I am, Sirs, yours faithfully,

June 16th 1899

CLAY AND GLOVERING AS A DRESSING FOR INFLAMMATION CONDITIONS

To the Editors of THE LANCET

SIRS—I understand that a surgical dressing of clay and was very popular in Great Britain some 30 years ago and used quite largely in the army and navy. Can you or any of you give me any information on the subject or mention any matter bearing on the subject? The dressing or poultice was used in inflammation.

I am, Sirs, yours faithfully
